FRUIT: Cones, ovoid-cylindric to narrowly conical, sessile, 3 to 6” long, buff rust brown, umbo dorsal and armed with a stout, sharp, recurved spine, grouped 2 to 5 together.

CULTURE: Easy to transplant, may develop a short taproot but it ceases growth in favor of an extensive lateral root system; grows on a wide variety of soils, prefers those with deep surface layers having abundant moisture and poor drainage; prefers acid soils.

DISEASES AND INSECTS: None particularly serious in normal context of the landscape; pine beetle can devastate plantings, fusiform rust, heart and butt rot.

LANDSCAPE VALUE: Not a graceful pine but very adaptable to extremes of soil and therefore valuable in South where the more graceful species do not thrive; good for fast screen in early years; one of the pioneer species along river bottoms; one particular abandoned bottomland agricultural field at the University's Botanical Garden was rapidly invaded by this species; is being used more frequently as a quick screen in southern landscapes, frequently container-grown and is easily transplanted.

CULTIVARS:

'Al's Dwarf'—Compact and dense, dark green needles; found by Albert Durio, offered by Louisiana Nursery.

'Nana'—Raulston described several 30-year-old dwarf loblollies that originated from "witches' brooms," 8 to 15' tall with dense rounded crowns; I have seen the plants and they are truly artistic and imbued with character; now (2008) much larger, some 25 to 30' in height.

PROPAGATION: Seeds germinate without pretreatment.

ADDITIONAL NOTES: One of the leading commercial timber species in the southeast United States. On cutover areas in the South, the species has spread to a remarkable degree and is aggressive in forming pure stands in old fields. Have seen it growing in the reddest of red clay where few other species proliferate. I have come to appreciate the beauty of this species particularly in my travels through the Southeast. It is one ubiquitous pine, colonizing highway cuts, banks, ditches, open grassy fields, and abandoned agricultural land. In eroded, red clay, that resists other vegetation, *P. taeda* manages a toe-hold. Many landscapers utilize this species for screens, groupings, buffers because of the fast growth and wholesale adaptability. Considerable controlled breeding by Forestry companies and was told about genetically superior trees that grew 70' high with 14" trunk diameter in 14 years. Whereas, everyday *Pinus taeda* seedlings cost \$35.00/thousand; the "super seedlings" sell for \$450.00/thousand.

NATIVE HABITAT: Southern New Jersey to Florida, eastern Texas and Oklahoma. Introduced 1713.

RELATED SPECIES:

Pinus clausa (Champ.) Vasey., (pī'nus claw'sa), Sand Pine, is a 2-needed (sometimes 3), small tree, 30 to 40' high, with shiny rich green needles. I observed the tree in northern Florida at Superior Trees where it served as a windbreak. In late February, the color was exceptionally rich green. Needles range from 1 1/2 to 3 1/4" long, are slender, straight or slightly twisted. Cones of two kinds: open and unopen (until fire), 2 to 3" long, ovoid-oblong, scales hard and inflexible, umbo with prickle, scale darker brown at tip than remainder of the surface. Grows in deep, well-drained, infertile sands in the wild. National champion is 72' by 29' in Aiken, SC. Native to Florida, southwestern Alabama. Zone 7 and 9.

Pinus elliottii Engelm., (pī'nus el-i-ot'ē-ī), Slash Pine, is more coastal in distribution from South Carolina to Florida west to southeastern Mississippi and Louisiana and represents an important timber species in those areas. It is a tall tree with ovoid crown, reaching over 100' high. Not unusual on the Georgia coastal islands like St. Simons and Jekyll to see 80' high trees. National champion is 144' by 54' in Jacksonville, FL. Needles are variable, occur in 2's with a few 3's or 2 and 3 per fascicle well intermixed, 4 to 9"(12") long and glossy dark green. The stalked (~1") cones are lustrous chestnut brown, 3 1/2 to 6" long, ovoid, with a short, stout prickle at the end of each cone scale. The bark is purple to red-brown at maturity, forming large, irregular blocks not unlike *P. echinata*, with scaly, flaking plates. Found in wet flat woods, interdune hollows and near coastal sands mixed with sand live oak, *Q. myrtifolia*. Has grown quickly in the Georgia trials. Zone 8 to 10.

Pinus glabra Walt., (pī'nus glā'bra), Spruce Pine, is a handsome 40 to 60' high, oval-rounded crowned species. Needles are dark green, 2 per fascicle, spirally twisted and 2 to 4" long. The cones are brown, 1 3/4 to 3 3/4" long, the scales with minute prickles. Cones may persist 2 to 4 years. Bark is dark gray and smooth at first, finally closely ridged-and-furrowed, producing small, thin, reddish brown plates suggestive of *Picea* bark. The national champion is listed at 156' by 70' in Bienville National Forest, MS. An immense, 80 to 90' high tree in the Coker Arboretum, probably about 100 years old, is the most magnificent I have witnessed. The bark is gray, ridged-and-furrowed and not at all as described as suggestive of *Picea* species. However, one tree does not umbrella a species. Found scattered on uplands, bluffs, slopes of ravines, in floodplain forests where flooding is shallow and brief. Have tested it in field plots in Athens and winter wind and sun induce yellow, off-color foliage. One of the more shade tolerant pines. Observed in low, wet areas around Statesboro, GA. South Carolina to northern Florida to Louisiana. Zone 8 and 9(10).

Pinus palustris Mill., (pī'nus pa-lus'tris), Longleaf Pine, is among the most unique of the southern pines because of the grass stage where seedlings produce dense, long, spreading needle fascicles, but minimal height extension. The tree grows 60' in landscape situations and the national champion is 106' by 36' in Montgomery, NC. The dark green needles are in fascicles of 3, occasionally 2, 6 to 12" long (up to 18"). The

ovoid-oblong, brown, 6 to 8"(10") long cones (up to 5" wide at base) open promptly and abscise over the winter following maturation. Not a plant for everyday use but intriguing. On trips to the coast, from Metter to Savannah, GA, the broomy-grassy stage of Longleaf Pine is common in the sandy or clay-sand ridges along with the scrub oaks. Southeastern Virginia to Florida, east to Texas. Zone 7 to 10. Introduced 1727.

Pinus thunbergii Parl. — Japanese Black Pine

(pī'nus thun-bērj'ē-ī)

LEAVES: Two, persisting 3 to 5 years, densely crowded, twisted, more or less spreading, 2 1/2 to 4 1/2" long, 1/12" wide, apex stiff, fine-pointed, rigid, margins finely toothed, with stomatic lines on each surface; very lustrous dark green; leaf sheaths 1/2" long, ending in two long, thread-like segments, persistent.

BUDS: One of the few conifers in which the buds provide a good identification feature; the terminal buds characteristically ovoid-cylindrical, apex-pointed, 1/2 to 3/4" long (may be longer), not resinous, scales appressed, tips free, gray or silvery white (very prominent), fimbriated.

STEM: Light brown, glabrous, ridged with the scale leaves persisting during the first year; in the second and third year blackish gray.

SIZE: 20 to 80' in height with a greatly variable spread, usually 20 to 40' under cultivation.

HARDINESS: Zone (5)6 to 8, -10 to -15°F will burn the needles.

HABIT: In youth artistically uneven but more or less pyramidal, in old age with spreading often pendulous branches, however, young trees can be pruned into a full dense specimen.

RATE: Medium.

TEXTURE: Medium.

BARK: On old trees blackish gray, soon becoming fissured into elongated irregular plates.

LEAF COLOR: Dark green, very handsome.

FLOWERS: Monoecious.

FRUIT: Cones subterminal, solitary or clustered, short-stalked, spreading, symmetrical, ovoid to conical, 1 1/2 to 3" long, 1 1/4 to 1 3/4" wide; scale end flattened, shiny light brown; umbo depressed, small, obtuse or with a minute prickle.

CULTURE: Transplants easily balled-and-burlapped if root pruned or from containers; makes its best growth on moist, fertile, well-drained soils; will grow on sandy soils and has been used for reclaiming sand dunes and other protective work near the shore; quite salt tolerant and has been used where foliar salts present a cultural problem; best in full sun; displays heat and drought tolerance; many in coastal North Carolina growing literally in sand next to the Atlantic and quite prosperous.

DISEASES AND INSECTS: Abundant branch dieback (*Diplodia* ?) on plants in Zone 7 and 8. A nurseryman and I were discussing the merits of this species and asked whether the other had ever witnessed a robust old specimen, the answer was NO! Life span has been 5 to 10 years on the Georgia campus.

LANDSCAPE VALUE: Because of its tolerance to salt spray it is invaluable for seashore plantings and useful in stabilizing sand dunes; also a good accent or bonsai plant; in 1985 several 4 to 5' plants were used as an irregular mass to screen a clay hillside at the University's Botanical Garden, by fall of 1989 the plants had grown 10 to 12' high and filled in without any pruning, their habit was somewhat irregular, the lustrous deep green needles and white, candle-like buds were particularly handsome; these plants were dead by 1997, see the discussion under DISEASES AND INSECTS.

CULTIVARS: Stanley & Sons 2007–2008 catalog lists 36 *P. thunbergii* taxa.

'Compacta'—Dense irregular large shrub type.

'Frosty Patches'—Yellow shoots mixed with green; not particularly vigorous.

'Globosa'—Large dense globe habit, dark green needles.

'Iseli' ('Aocha Matsu')—Gold-variegated, broad pyramidal form, 7' by 3'.

'Kotobuki'—Small, pyramidal, with bright green, short needles.

'Majestic Beauty'—Habit like species, but more dense and compact, with lustrous dark green needles, resistant to smog, cutting propagated, Monrovia introduction.

'Mini Mounds'—Good name for this 2 to 4' high, 7 to 9' wide, 23-year-old selection; closely spaced, 3 to 5"(8") long needles that are bunched to form mounds; Vermeulen introduction.

'Mt. Hood Prostrate'—Dramatic low sweeping habit, dark green needles, 6 to 8' high, 8 to 12' wide; Iseli introduction.

'Oculus-draconis'—Needles are banded with yellow (2 bands) like *P. densiflora* 'Oculus draconis', very stiff appearance and wide-spreading habit; for the collector.

'Pygmaea'—Compact form with rich green needles, 5' to 4'; Iseli.

'Shioguro'—Compact, globose with bright green, long needles.

'Thunderhead'—Heavy bud set, i.e., white, candle-like buds above heavy, dense, dark green needles; dwarf, broad habit; Angelica Nursery introduction.

PROPAGATION: Seeds have no dormancy and will germinate immediately upon planting.

ADDITIONAL NOTES: I conducted considerable salt tolerance research and in one comparative study between this species and *P. strobus* found that *P. thunbergii* was tremendously salt tolerant. Apparently, it is able to exclude the sodium and chloride ions and thus resist injury. White Pine accumulated chloride at levels greater than 2% of needle dry weight and died. For a rather complete listing of salt tolerant plants see Dirr, *Journal of Arboriculture* 2:209–216 (1976). See Townsend and Kwolek, *J. Arboriculture* 13(9): 225–228 (1987) for a discussion of the salt-tolerance of 13 pine species.

NATIVE HABITAT: Japan, Korea. Grows by the seashore. Introduced 1855.

Pinus virginiana Mill. — Virginia (Scrub) Pine, Jersey Pine, Spruce Pine, Poverty Pine
(pī'nus vē-jin'ē-ā'na)

LEAVES: In two's, remaining 3 to 4 years, twisted, spreading, stout, 1 1/2 to 3" long, margins with minute, irregular teeth, apex sharp-pointed, yellow-green to dark green; sheath persistent, 3/16" long.

BUDS: Ovoid with a short point, 1/3 to 1/2" long, resinous with closely pressed scales.

STEM: Young-slender, reddish purple with a pale bloom; good way to separate it from *P. banksiana* and *P. sylvestris*.

SIZE: 15 to 40' in height by 10 to 30' spread; respectable 60' plants at Bernheim Arboretum and Tyler Arboretum; national champion 91' by 43' in Arlington, VA.

HARDINESS: Zone 4 to 8.

HABIT: A broad, open pyramid, becoming flat-topped, the branches springing irregularly from the stem; finally low, straggling, scrubby, with long outstretched limbs.

RATE: Slow.

TEXTURE: Medium.

BARK: Thin and smooth, eventually scaly-plated, reddish brown, 1/4 to 1/2" thick.

LEAF COLOR: Yellow-green to dark green; often sickly yellowish green in winter.

FLOWERS: Monoecious; staminate orange-brown, pistillate pale green.

FRUIT: Cones 2 to 4 together or solitary, short-stalked or sessile, spreading or deflexed, oblong-conical, symmetrical, 1 1/2 to 3" long by 1 to 1 1/4" broad, apex blunt, dark brown; maturing in the second autumn but often persistent after that; cones sharp due to prickly-like appendage.

CULTURE: Does well in poor, dry soils where other pines will not grow; best on clay loam or sandy loam; dislikes shallow, chalky soils; open, sunny exposure.

DISEASES AND INSECTS: See *Pinus* introduction.

LANDSCAPE VALUE: Not very ornamental but valuable as a cover for dry and barren soils; served as the basis for the Christmas tree industry in the southern states, losing some of its steam because of Leyland Cypress intrusion and the extensive Fraser Fir production in North Carolina and Virginia.

CULTIVARS: Stanley & Sons 2007–2008 catalog lists 6 cultivars of *P. virginiana*.

'Wate's Golden'—Golden needles in winter, green in summer, start to change to yellow-gold in October–November; quite effective in the cold-weather landscape and combines well with the red, gold, yellow, orange-stemmed, shrubby *Cornus*.

ADDITIONAL NOTES: Chief merit lies in its ability to reproduce and grow on heavy, clay land where few other plants will grow, both on virgin soil and impoverished farm land.

NATIVE HABITAT: Long Island, New York, southwestward to central Alabama, in the Appalachian, Ohio Valley, Piedmont, and part of the Coastal Plain regions. Introduced before 1739.

Pinus wallichiana A.B. Jacks. — Himalayan Pine, Bhutan Pine; also called *P. griffithii* McClelland
(pī'nus wâl-lik-ē-ā'na)

LEAVES: Five, persisting 3 to 4 years, on young shoots more or less erect, the older ones spreading or drooping, slender, flaccid, creating a feathery effect, 5 to 8" long, apex sharp pointed, grayish green to blue-green, margin minutely toothed, with glaucous, white stomatic lines inside, outside green, leaf sheaths about 3/4" long, soon falling, needles often bent abruptly near base so greater part of needle is pendulous.

STEM: Stout, bluish green, glabrous, slightly ridged below each bundle of needles towards the apex.

SIZE: 30 to 50' high under landscape conditions but can grow to 150'; spread is variable but the large specimens I have seen were 1/2 to 2/3's the height.

HARDINESS: Zone 5 to 7; shows considerable needle browning when temperatures drop below –15°F.

HABIT: Loosely and broadly pyramidal when young; graceful, of elegant habit and often feathered with branches to the ground in old age; tends to be more wide-spreading than many pines as it approaches maturity.

RATE: Slow-medium, in youth may grow 2 to 3' per year.

TEXTURE: Medium.

LEAF COLOR: Gray-green to blue-green.

FLOWERS: Monoecious.

FRUIT: Cones subterminal, solitary, on a 1 to 2" long stalk, erect when young; pendulous the second year, cylindrical, banana-shaped, 6 to 10" long by approximately 2" broad, light brown when ripe and very resinous.

CULTURE: Listed as somewhat difficult to transplant and should be moved as a young plant to a permanent location; soil requirements are similar to those for White Pine and a sandy, well-drained, acid loam is best; full sun; not recommended for shallow, chalky soils; severe winter winds can result in needle browning; withstands atmospheric pollutants better than most conifers; in extremely exposed locations the top becomes thin and weak when the tree is 25 to 40' high and, therefore, a sheltered position is desirable.

DISEASES AND INSECTS: See *Pinus* introduction.

LANDSCAPE VALUE: Excellent and beautiful pine for large areas, very graceful in effect; a lovely specimen tree; apparently there are differences in hardiness among nursery-grown trees (related to origin of seed) for some trees will do well in the Midwest and others succumb after a difficult winter; the Morton Arboretum has a lovely, well-formed specimen from which seed or scion wood should be collected for the midwestern states.

CULTIVARS: There is a yellow-banded clone which is listed as 'Oculus-draconis' by some authorities; however, Den Ouden and Boom categorize the clone as 'Zebrina' which they describe as having leaves barred, marked an inch below the apex with a cream-colored band, otherwise green and gold. I have seen this cultivar at the U.S. National Arboretum in the Gottelli Conifer Collection. Perhaps as striking and interesting a cultivar as one could hope to see among the pines. There are three 'Oculus-draconis' clones; one is *P. densiflora*, another is *P. thunbergii*, and the above. All are interesting but difficult to blend into the average landscape. For the hobby gardener they offer a worthwhile challenge. Other cultivars are known. Stanley & Sons 2007–2008 catalog lists 4 *P. wallichiana* taxa.

PROPAGATION: Seeds have no dormancy or a slight one and may require 15 days of stratification.

NATIVE HABITAT: Temperate Himalaya at 6,000 to 12,500' elevation, extending westward to Afghanistan and eastward to Nepal. Introduced 1827.

RELATED SPECIES:

Pinus armandii Franch., (pī'nus är-man'dē-ī), David's Pine, Chinese White Pine, Armand's Pine, is closely allied to the above species and differs in its relatively broad, scarcely tapered, 4 to 8" long, 2 1/2 to 3" wide, thick-scaled cones. The needles occur in 5's, persistent for 2 to 3 years, 4 to 7" long, glossy green on outside, glaucous on inner sides; pointed at apex and minutely toothed on the margin; the sheath soon falling away. It makes a graceful, broad pyramid in youth. It is as handsome as *P. wallichiana* but supposedly less hardy. I am not sure this is the case and degree of hardiness would no doubt reflect the provenance of the seed. It is a beautiful tree that certainly deserves consideration for landscape use. The large cones are quite resinous and my initial introduction to the species came at the expense of resin-coated hands when I plucked a beautiful, unripened, glaucous, green cone from a tree at the Arnold Arboretum. The cones are so large and heavy as to partially weigh down the branches. Several varieties are described but I have not seen them in cultivation. Western and central China, southeastern Tibet, Taiwan and Korea. Introduced 1895. Zone 5 to 7?

Pistacia chinensis Bunge — Chinese Pistache or Pistachio

(pis-tā'shi-a chī-nen'sis)

FAMILY: Anacardiaceae

LEAVES: Alternate, compound even pinnate, about 10" long, 10 to 12(20) leaflets, each leaflet 2 to 4" long, 3/4" wide, terminal leaflets the shortest, lanceolate, short-stalked, acute or acuminate, mucronate to cuspidate, oblique, entire, glabrous at maturity, lustrous dark green; petiole—1 to 4" long, puberulous.

BUDS: Terminal—1/4 to 3/8" long, imbricate, brownish black, ovoid, composed of stout, mucronate keeled bud scales, glabrous to slightly pubescent; vegetative—1/8 to 1/4" long, similar to above in color, directly centered over leaf scar.

STEM: Stout, light brown, prominently covered with orangish lenticels, glabrous with prominent odor when bruised; leaf scars raised, shield-shaped; pith-white, solid, ample.

SIZE: 30 to 35' high, spread 25 to 35', can reach 50' by 40'.

HARDINESS: Zone 6 to 9.

HABIT: Oval-rounded to rounded in outline; main branches may be upright-arching; have seen many specimens of the tree in the Athens-Atlanta areas and most were oval-rounded with upswept branches; rather unorganized growth habit in youth, becoming more uniform and handsome with age.

RATE: Medium, however, may grow 2 to 3' per year under good cultural conditions.

TEXTURE: Medium in leaf, coarse in winter.

BARK: Develops shallow furrows, the ridges becoming scaly, gray to gray-black in color; as the scales flake off they expose a salmon to orange inner bark.

LEAF COLOR: Late leafing as most oaks and maples have a complement of foliage; dark green in summer, often lustrous; hold rather late in fall, becomes brilliant orange and orange-red; for the southern states this is the closest thing to rivaling Sugar Maple for fall color; over the past 30 years I have monitored the quality and progression of fall color, color will vary from yellow-green to vivid orange-red and red, and the best forms need to be propagated; in the Athens area color develops about mid-October and often extends into late November, leaves sometime present into early December.

FLOWERS: Dioecious, small, greenish, male in dense, 2 to 3" long panicles; female in 7 to 9" long, loose panicles, not showy, early to mid April before leaves; flowers occur on previous year's wood; almost look like foliose lichens on the bare branches.

FRUIT: A globose to obovoid, 1/4" diameter drupe, typically maturing to robin's egg blue or red in the same fruit cluster; fruits are reasonably showy but certainly not the reason for using the tree, old fruit stalks persist on some trees and are less than aesthetic; fruits ripen in October and either fall or are taken by birds before late November.

CULTURE: Transplants well balled-and-burlapped or from containers; very adaptable species, tolerates a wide range of conditions but makes its best growth on moist, well-drained soils; very drought resistant; full sun; needs pruning in youth to form a good crown; in Kansas tests it averaged 1'1" per year over a 10 year period and prospered in dry sandy soils.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Too long neglected in the southern states for lawn, park, and street use; selections should be made for good habit and excellent fall color; its ability to withstand poor, droughty soils holds it in good stead as an urban tree; trees in Athens, GA are thriving; I am most impressed by its complete freedom from insects and diseases; have observed great trees in Savannah and Tifton, GA and Woodward, OK where dryness and wind are ways of life; in fact, the Woodward tree was 25' by 30', broad-rounded, uniform, dense, and dark green on September 12, 1992; one of the best street trees in Birmingham, AL; if superior clones are identified, propagated and marketed the tree will become commonplace; a truly tenacious species.

LANDSCAPE MAINTENANCE: As a young tree the habit is best described as gawky. Seedlings do not develop straight trunks and may produce multiple leaders. Some staking and pruning are necessary to produce a decent trunk. Once developed, the head seems to follow without a great deal of manicuring. My observations indicate that male trees are much neater and uniformly branched than the females.

CULTIVARS:

'Keith Davey'—Described in a California publication as a selected male form that is neater and easier to shape.

'Pearl Street (PP 9,242)—Male selection characterized by rapid growth and large trunk caliper, upright branches that average 52° angle branch attachments, trunk and scaffold branches with strong apical dominance, and tall, dense, globe-shaped crown; introduced by Peter Cowles and Allen Lagarbo, Modesto, CA; selected from 6,000 seedling trees growing in Modesto, CA.

Sarah's Radiance™—Consistent orange-red fall color; 35' by 30'; female; Zone 6; introduced by Mountain States Wholesale Nursery, Litchfield Park, AZ.

PROPAGATION: One report stated that the pulp should be removed from the seeds, the seeds soaked in water for 16 hours then sown. From actual experience I have found the following to be reasonably foolproof. First and most important is the collection of sound seed. Only collect the bluish fruits for these have solid seed.

I tried cut tests on a great number of reddish fruits and they were invariably hollow. Clean pulp from the seeds, place seeds in a moist medium at 41°F and observe for radicle emergence. In our work, 54 days proved optimum, for many seeds had germinated in the bag. These were then sown and the germination percentages were in the 80 to 90% range. Seed was sown directly and not a single one germinated. Cuttings: Morgan obtained 52% rooting of terminal cuttings with 1/3" old wood attached, mid-May, 15,000 ppm KIBA, mist, cuttings were collected from a mature, 45-year-old tree; with terminal new growth only, rooting was 20%; mid-June and August cuttings did not root as well. Grafting and budding have proven difficult. Mini-treatise on success with mounding in *North American Regions Plant Propagator* 8(2):20 (1996); more shoots were produced when plants were cut 2" above soil line; rooting averaged 77% and 75% on wounded shoots plus 1.75% IBA; this might be a useful method for what is considered a recalcitrant rooter. Similar information, more detailed, in *J. Environ. Hort.* 13:109–112 (1995). Another study, same principal author, *J. Amer. Soc. Hort. Sci.* 121:269–273 (1996) assessed degree days and rooting; highest rooting was 44%, green softwood, 380 days after bud break, 8,750 ppm IBA, from 34-year-old tree.

ADDITIONAL NOTES: Have seen the species as far north as Urbana, IL where it was far from happy but did survive. It is really a tree for Zone 7 through 9. Is used in California to a considerable degree. Used as an understock for the pistachio nut, *Pistacia vera* L., of commerce. In China, the young shoots and leaves are eaten cooked as a vegetable. E.H. Wilson collected seeds of the species during his 1908 and 1910 expeditions to China. He noted that it turned a gorgeous crimson in the fall. Anyone interested in additional information should read Gary Koller's account in *Arnoldia* 38: 157–172 (1978). Also see McMillan Browse, *American Nurseryman* 167(1): 115–120 (1988), for excellent propagation and cultural discussion. Also, *Pistacia texana* Swingle, a shrub/tree species with smaller evergreen leaflets is growing contentedly in Wilmington, NC at the New Hanover County Arboretum.

NATIVE HABITAT: Central and western China, Taiwan, Philippines. Introduced about 1890.

Pittosporum tobira (Thunb.) Ait. — Japanese Pittosporum, Tobira

(pit-o-spō'rum to-bī'ra)

FAMILY: Pittosporaceae

LEAVES: Alternate, simple, evergreen, obovate, 1 1/2 to 4" long, 3/4 to 1 1/2" wide, blunt or rounded at apex, tapering to a short petiole, glabrous, entire, margins revolute, leathery, lustrous dark green, with a paler green midvein above.

SIZE: 10 to 12' high, spread 1 1/2 to 2 times height; 15' high, wide-spreading, architecturally handsome plant on Tulane campus; picturesque spreading plants 20 to 25' high have been reported.

HARDINESS: Zone 8, preferably lower portion, to Zone 10; plant is often flattened in Athens-Atlanta by cold but in Macon and Augusta, GA prospers, distances of 100 to 120 miles south.

HABIT: Dense, compact, broad-spreading evergreen shrub of impenetrable proportions.

RATE: Slow.

TEXTURE: Medium.

LEAF COLOR: Lustrous dark green throughout seasons, emerging leaves, early April, more frost tolerant than I imagined, withstood 26 to 27°F.

FLOWERS: Perfect, 5-petaled, fragrant (orange-blossom scent), creamy white becoming yellow with age, 1/2 to 1" diameter, borne in terminal, 2 to 3" diameter, umbellate clusters, April–May; somewhat inconspicuous but wonderfully fragrant.

FRUIT: Odd-looking, 3 valved, pear-shaped, 1/2" diameter capsule, green, yellow, changing to brown, capsule dehisces to expose the fleshy orange coated (aril) seeds in September–October.

CULTURE: Easily transplanted from containers, adaptable, sandy soils to clays as long as well-drained; acid or alkaline; used extensively in Florida; seems to thrive in sandy soils and hot, dry locations; full sun or heavy shade; withstands heavy pruning; tolerates salt spray.

DISEASES AND INSECTS: Tough, durable plant but can contract leaf spot disease and mealy bugs; a Florida publication through their cooperative extension service, *Plant Pathology Fact Sheet PP-29*, lists 10 diseases of this species.

LANDSCAPE VALUE: Overused in warmer areas of South; mass plantings are popular, foundation use, in drifts under trees; hedges, screens, buffer or barrier planting; handsome plant for containers, patio tubs.

CULTIVARS:

'Compacta'—Compact, dense, spreading.

'Compacta Green'—Listed in Florida literature, have been unable to track origin, mentioned in *HortScience* 27:1198 (1992).

Cream de Mint™ ('Shima', PP 6,449)—Tightly mounded form, 2 to 2 1/2' high and wide; soft mint green leaves with cream-white variegation.

'Laura Lee' ('Lauralee', PP 5,893)—Compact form like 'Wheeler's Dwarf', with uniform white flecking throughout the leaves; experienced the plant for the first time (March 25, 1993) on St. Simons Island, GA, have not seen it since.

Louisiana Hardy Form ('Louisiana Compact')—Beautiful large, lustrous dark green leaves on compact framework, 6 to 8' high and wide; McCorkle Nurseries, Dearing, GA was growing this form, might be suitable in Zone 7, tested in Athens and not hardy.

Mojo® ('CNI Three', PP 16,188)—Potent cream-white variegated leaves; compact habit, 18 to 22" by 36 to 48"; increased cold hardiness over species, plant in our Chapel Hill garden suffered in winter of 2006–2007; a grouping at the New Hanover County Arboretum, Wrightsville Beach, had bleached to uniform cream-brown, no demarcation of cream-white-green, these were the previous year's leaves, May 10, 2007; a Carolina Nurseries introduction.

'Spring Snow'—New growth is almost pure white, slowly turning green as it ages, subsequent flushes are white even in Zone 7 heat; from Ted Stephens at Nurseries Caroliniana.

'Tall 'N Tough'—Looser than typical species form as I viewed this JC Raulston introduction, may be more cold hardy as seedlings were grown from Korean seed, at best Zone 7 if sited away from wind and sun; listed at 10 to 12' by 10 to 15' by Hawksridge Nursery.

'Turner's Variegated Dwarf' (Turner's Pitt™, PP 4,919)—Green foliage edged in white; low and compact, 2 to 3' high and wide; severely injured in 2004–2005 winter at Raulston Arboretum; Zone (8)9.

'Variegatum'—Leaf is edged with white, green areas take on a gray-green color, can be blended with green form for handsome effect; might not be as cold hardy as species; extremely popular and overused; grown as a house and conservatory plant in the North; flowers with same wonderful fragrance as species; 6' or more at landscape maturity.

Variegata Winter Pride®—Grows 8 to 12' high; like 'Variegatum' but more cold hardy; Hines Nursery introduction.

'Wheeler's Dwarf'—Compact form of the species growing 3 to 4' high and wide; forms a compact mound of dark green foliage, all parts smaller than the species; not as cold hardy as species and generally not as adaptable, can be used as a houseplant; at 0 to 5°F, bark split devastated this cultivar; in Savannah, GA a large mass planting was killed outright at 10°F; this cultivar is a Zone (8)9 plant at best; a friend gave me a plant for our garden and after two winters with nothing below 5°F, it was the worst for wear.

Winter Pride® ('Hines Hardy', PP 7,304)—Green foliage, more cold hardy, otherwise like species; Hines Nursery introduction; how unique, I do not know.

PROPAGATION: Seeds germinate readily when cleaned of the orange-red aril (coat); have grown numerous seedlings always questing for compactness and cold hardiness; although variation in seedling foliage and habit was great, cannot find cold hardiness. Dr. John Ruter, Horticulture, Georgia, is also breeding *P. tobira* for increased hardiness. Use firm wooded cuttings, 1,000 to 3,000 ppm IBA-talc or solution, well-drained medium, mist; have observed considerable "rot" under excessively moist propagation conditions. Wang, *J. Environ. Hort.* 9:199–203 (1991), reported the species easy to root, in fact, rooting was excellent in all months studied: February, April, June, October, and December. Lamb, *The Plantsman* 10(4):251–252 (1989), reported seed, cutting, and grafting procedures for *P. tenuifolium*.

ADDITIONAL NOTES: Something approaching 200 species have been documented. Most are tender and the genus as a whole is listed as Zone 9. In Scottish and Irish gardens, many species are grown but the most common is *P. tenuifolium* Gaertn., Tawhiwhi or Kohuho, a New Zealand native. It forms a 10 to 20'(30'), slender, conical, dense-foliaged, evergreen shrub or tree. Numerous cultivars with foliage of yellow, gray, cream-variegated, purple, almost black and dark green are known. At Mt. Congreve, Ireland, I still reflect on the kaleidoscopic variation in leaf coloration. Another species, *P. ralphii* T. Kirk, is an evergreen, 7 to 15' high shrub with dark crimson flowers. It hybridizes with *P. tenuifolium*. *Pittosporum heterophyllum* Franch. is a pleasant surprise in the Athens trials. Lustrous medium green, narrow obovate to lanceolate leaves, 1 to 1 1/2" long, densely set, on a broad-rounded shrub to 8 to 10' high and wide. Our plant remained dense without pruning and would serve as a loose screen or fine-textured hedge. Flowers, white, May, fragrant, age to yellow, borne in the axils of the leaves. Easy to root from cuttings. Has been cold-hardy in the 5 to 10°F range. A landscape sleeper that gardeners would enjoy. Grows in sun to partial shade. Not fussy about soils. 'Variegatus' has cream-margined leaves, smaller and slower growing, but attractive. Might prove a showy container plant. 'Winter Frost' has leaves with irregular white margin, rich green centers; white, aging to yellow, fragrant flowers, not sure relative to size; listed as Zone 7; might be the same as 'Variegatus'. Dr. Ruter has a small, compact form with shiny green leaves that could serve as a dwarf holly alternative.

NATIVE HABITAT: Japan, the Ryukyus, Taiwan, Korea and China. Introduced 1804.

Planera aquatica (Walter) J.F. Gmel. — Water Elm

(plan-er'a a-kwat'i-ka)

FAMILY: Ulmaceae

Planera aquatica, Water Elm, is appropriately named as it grows in wet, swampy habitats in the Southeast.

Generally a small, spreading tree, 20 to 30', with gray to light brown, thinnish bark, that with age develops flat scales which exfoliate, exposing the reddish brown inner bark. Leaves are elm-like, shiny medium green, 1 1/4 to 2 1/2" long, broad-ovate, glabrous above, acute, base asymmetrical, serrate to doubly serrate, petiole about 1/4" long. Flowers with leaves, April–June, male, female and bisexual on same tree; fruits one-seeded, 1/3" long, nutlike drupe with irregular crested, fleshy ribs. Waterfowl apparently eat the fruits. Might be a worthy tree for wetlands mitigation. Nowhere common and a handsome, small, 25' specimen grew at the Raulston and prospered there for many years in full sun and dry soil. Obviously moist environments maximize performance. Species may grow as large as 75' with a 32" trunk diameter. National champion is 56' by 84' in Williamsburg, VA. Zone 6 to 9. Monotypic species, i.e. only species of the genus. Southern North Carolina to Florida, west to southern Illinois and south to Oklahoma and Texas. Introduced 1816.

Platanus ×acerifolia (Ait.) Willd. (Result of a cross between *P. orientalis* × *P. occidentalis*, sometimes listed as *P. ×hybrida* Brot.) — London Planetree

(plat'a-nus a-ser-e-fō'lē-a)

FAMILY: Platanaceae

LEAVES: Alternate, simple, 6 to 7" long, (5)8 to 10" wide; 3- to 5-lobed, with triangular-ovate or broad triangular, not or sparingly toothed lobes, with acute or rounded sinuses extending 1/3 the length of the blade, truncate to cordate at base, glabrous or nearly so at maturity, medium to dark green; petiole—2 to 4" long.

BUDS: Similar to *P. occidentalis*.

STEM: Similar to *P. occidentalis*.

BARK: Olive-green to creamy, exfoliating; actually one of the best assets of the tree.

FRUIT: Rounded, syncarp of achenes, bristly, 1" across, 2 per stalk, rarely 1 or 3.

SIZE: 70 to 100' in height with a spread of 65 to 80' although can grow to 120' or more.

HARDINESS: Zone (4)5 to 8(9); not happy in central Florida.

HABIT: Pyramidal in youth, developing with age a large, open, wide-spreading outline with massive branches; does not spread as much as *P. occidentalis* but nonetheless is still not acceptable for small area use.

RATE: Medium, 35' over a 20-year period, in Kansas tests grew 1'11" per year over a 10 year period; under nursery production practices literally grows like a weed.

TEXTURE: Medium-coarse, but not particularly offensive; superb in winter when the bark is maximized.

BARK: Perhaps the handsomest of all large trees for winter character because of cream, olive, light brown bark; no two trees are exactly similar and large trees in Hyde Park, London; Berne, Switzerland; Mainau, Germany; Cambridge, MA; Washington, DC; Vancouver, B.C. and the great *allée* at *Jardin des Plantes*, Paris flash into view; all are spectacular, all remembered because of noble habit and exquisite bark.

LEAF COLOR: Flat medium to dark green in summer, yellow-brown in fall.

FLOWERS: Monoecious, April, not showy, male and female similar in dense globose structures but on separate peduncles; develop with leaves.

FRUIT: Syncarp (multiple fruit) of elongated, obovoid achenes, 1" diameter, ripening in October and persisting late into winter, usually borne 2 together although 3's and singles occur.

CULTURE: Easily transplanted; prefers deep, rich, moist, well-drained soils but will grow in about anything, withstands high pH conditions and pollutants; full sun or very light shade; prune in winter; withstands smoke and grime of cities and was so widely planted in London because of its adaptability that it acquired

the name London Planetree; hardiness in Zone 4 and 5 is not guaranteed and individuals may or may not survive; Capiello, Orono, ME, Zone 4, reported outright kill; Morton Arboretum, Lisle, IL, Zone (4)5, reported variation in hardiness but an 82' by 55' specimen was on the grounds.

DISEASES AND INSECTS: Cankerstain (very serious), anthracnose, *Xylella fastidiosa* [more serious than I knew with the literature replete with references to dieback of sycamores, see *J. Arboriculture* 18:57–63 (1992)], *Botryosphaeria* canker, powdery mildew, American plum borer, and Sycamore lace bug; the London Planetree was touted as a "Super" tree by many people and was overplanted; many diseases have caught up with it and its use should be tempered, the cankerstain fungus is especially troublesome and I have seen trees badly infested with lace bug; frost cracking is common in the Midwest and anthracnose may occur on selected trees although the species generally shows degrees of resistance; considerable variation in anthracnose susceptibility among clones (see under CULTIVARS).

LANDSCAPE VALUE: Acceptable for open areas in parks, golf courses, campuses; use as a street tree should be restricted for it grows too large; in some respects its use has approached monoculture status; the influx of disease problems should be closely monitored; considering that the tree is seed-grown it shows good uniformity but some segregation occurs and types resembling either parent result.

CULTIVARS: Considerable interest in better selections with uniform characteristics. Several new cultivars may be superior to run-of-the-mill seedlings. In Europe, 'Augustine Henry', 'Cantabrigiensis', 'Hispanica', 'Kelseyana', 'Pyramidalis', 'Sutternii' (cream-white-marked new growth, soon green), and 'Tremonia' are known.

'Bloodgood'—Greater resistance to anthracnose than the species and after 10 years was the 10th rated tree in the Shade Tree Evaluation Tests at Wooster, OH; tolerates soil compaction, heat, drought, as well as severe pruning and is rapid-growing; unfortunately, the severe winters of 1976–77, 1977–78 caused considerable injury and laboratory tests have indicated it is very susceptible to 0.5 to 1.0 ppm ozone, still a good selection and is being produced in greater numbers, 50' by 40' after 20 to 30 years, good dark green summer foliage, yellow-brown in fall; at Milliken Arboretum, Spartanburg, SC, this was the most severely infected with anthracnose, followed by 'Columbia', with no symptoms on 'Yarwood', perhaps the fungus has caught up with and surpassed 'Bloodgood's' early resistance.

'Columbia'—Original cross made by Dr. Santamour, U.S. National Arboretum in 1970 between *P. orientalis* (female) and *P. occidentalis* (male), pleasing pyramidal form in youth with dark green, mildew and anthracnose resistant foliage, compartmentalizes wounds well, grew 27' in 12 years, 4" diameter; 5-lobed leaves, length 80 to 90% of width; fruits in 2's and 3's; see *HortScience* 19(6): 901–902 (1984) for more detailed information.

Exclamation™ ('Morton Thornhill')—Uniform pyramidal growth habit, strong central leader, vigorous; resistant to anthracnose and powdery mildew, no frost cracking; light fruit production; exfoliating bark; 60' by 45'; Zone 4 to 8; bred by Dr. George Ware, Morton Arboretum, utilizing *P. orientalis* (naturally resistant) × anthracnose-resistant *P. occidentalis*; according to Keith Warren, J. Frank Schmidt & Son, Inc., Exclamation™ is better than Ovation™; introduced via Chicagoland Grows®.

'Liberty'—*P. orientalis* × *P. occidentalis* (bottomland tree), remotely 5-lobed leaves, fruits 1 to 2 with less than 1/3" between fruits, resistant to anthracnose and powdery mildew, readily compartmentalizes against decay organisms; tremendous growth at Milliken Arboretum with 6-year-old trees 20 to 24' high and 12 to 14' wide with a ±6" trunk diameter; bark does not exfoliate as early as 'Yarwood', also bark is more gray-green and not as cream-white as 'Yarwood' over time; some anthracnose; see *HortScience* 19(6): 901–902 (1984) for details.

Metroshade™ ('Metzam')—Pyramidal, described by the introducer as most vigorous growing of all the London Plane cultivars; foliage deep-green, mildew resistant; 60 to 70' by 60'; have seen at Spring Grove as a 20' tree, looked good; Lake County Nursery introduction.

'Mirkovec'—A shrubby form found in former Yugoslavia at the Mirkovec Nursery, introduced to western Europe via Belgium by the de Belder's at Kalmthout Arboretum; broad, finely lobed leaves are a mixture of pink, cream and bronze with prominent veins; have observed in England, unusual variant of a behemoth tree.

Ovation™ ('Morton Euclid')—Pyramidal in youth, oval and spreading with age, 60' by 50'; demonstrated good resistance to leaf anthracnose; attractive cream and brown bark; from Morton Arboretum, Lisle, IL. 'Yarwood'—Appears promising, in the 1990s I listed it as mildew resistant, after 17 or 18 years in the Milliken Arboretum, it appears the best of the improved selections; fast growth, tight pyramidal outline, disease-free, dark green leaves, early exfoliating, cream-colored aging to olive-brown bark; with 'Bloodgood' and 'Liberty' within a stone's roll, this exquisite form predominates; interestingly, fruits are borne singly suggesting *P. occidentalis* affinity; I am enamored with this cultivar's early performance; walked the Schmidt Arboretum in August, 2006 with horticulturist Keith Warren and he showed me an incredibly beat up 'Yarwood' from anthracnose, with 'Liberty' the best followed by 'Columbia'; Keith and I are still looking for the perfect tree; see *NMPro*. Shade tree development today means hope for the future. 23(1):12, 112 (2007) and How new shade trees are shaping the landscape. 23(2):12, 80 (2007).

Evaluation of anthracnose and mildew resistance of 'Bloodgood', 'Columbia', 'Liberty', 'Yarwood', and 'Saratoga 86-336-C' in *J. Arboriculture* 18:161–163 (1992) showed 'Bloodgood' significantly less affected by anthracnose, 'Yarwood' was most resistant to mildew. Study was conducted in an urban park in California.

PROPAGATION: Seed requires a cold treatment for 45 to 60 days; there is some indication that seeds will germinate without pretreatment. Softwood and hardwood cuttings can be rooted and this appears to be standard practice in European countries; best to use 8,000 ppm IBA, bottom heat, open bench with hardwoods. Myers and Still, *The Plant Propagator*, September 1979, 9–11, present interesting data relative to rooting June softwood cuttings; they collected the cuttings from a 45-year-old and a 20-year-old tree, dipped them in 50% alcohol solution, 8,000, 16,000, 32,000 ppm IBA; best rooting occurred with the control and was 100% for the 20-year tree and 95% for the 45-year tree; IBA at the 2 lowest concentrations was also effective but not better than control; NAA proved valueless. Winter hardwoods rooted 89–100% from 2- to 4-year-old trees.

ADDITIONAL NOTES: The history of the plant is interesting and I suggest the reader consult Bean for a fine account. The first record of the tree was in 1663 when the hybrid was found growing in London. It is widely planted in Europe and especially England where in London it is the dominant street and park tree. Bonnie and I walked through Hyde Park on a cool September day and admired the great beauty of the bark and massive trunks. I think it is safe to say I have changed my opinion of the species over the years. When properly grown, it is a fine tree. The tree withstands heavy pruning and is often pollarded and pleached to form hedges and allées. There is a magnificent allée at the Jardin des Plantes, Paris, that every visitor to that city should see and experience. Average life span of 39 years as street trees in Jersey City, NJ; see *J. Arboriculture* 17:303–305 (1991).

Platanus occidentalis L. — American Planetree, also known as Sycamore, Buttonwood, and Buttonball-tree

(plat'a-nus ok-si-den-tā'lis)

LEAVES: Alternate, simple, 4 to 9" wide, often broader than long, 3- or sometimes 5-lobed with shallow sinuses and broad-triangular lobes, truncate or cordate, rarely cuneate, coarsely toothed or rarely entire, floccose-tomentulose when young, at maturity pubescent only along veins beneath, medium to dark green; petiole—3 to 5" long, prominent stipules 1 to 1 1/2" long, entire or toothed.

BUDS: Terminal—absent, laterals—large, 1/4 to 3/8" long, conical, blunt-pointed, smooth, shiny dark reddish brown, with single visible scale formed within petiole base, second scale green, gummy, innermost scale covered with long rusty hairs; diverge at 45° angle.

STEM: Rather stout, round, smooth or pubescent, shiny yellow-orange-brown, generally zig-zag.

BARK: Red to gray-brown and scaly near base, exfoliating on upper trunk exposing lighter colored (white to creamy white) inner layers.

FRUIT: Multiple, globose fruit of achenes, 4/5 to 1 1/3" diameter, borne singly on a 3 to 6" long peduncle, occasionally 2 fruits per stalk.

SIZE: 75 to 100' in height with a similar or greater spread; can grow to 150' and next to *Liriodendron tulipifera* is one of our tallest eastern native deciduous broadleaf trees; national champion is 129' by 105' in Ashland, OH.

HARDINESS: Zone 4 to 9.

HABIT: Usually a tree with a large, massive trunk and a wide-spreading open crown of massive, crooked branches; a behemoth in the world of trees; a striking and impressive specimen especially in winter when the white, mottled bark stands out against the cold gray sky; the best description of habit would be irregular.

RATE: Medium to fast, in Kansas tests averaged 1'11" per year over a 10 year period.

TEXTURE: Coarse, but humanely so.

BARK: Mostly smooth, very light grayish brown, flaking off in large, irregular, thin pieces and exposing the grayish to cream-colored inner bark which gradually becomes whitish and produces the impressive mottled appearance.

LEAF COLOR: Flat medium to dark green in summer; fall color is tan to brown and unrewarding; leaves emerge late in spring.

FLOWERS: Similar to *P. xacerifolia*.

FRUIT: Also similar except the fruits are borne singly, slightly larger.

CULTURE: Similar to, but not as tolerant as *P. xacerifolia*; found native in bottomlands and along the banks of rivers and streams; attains its greatest size in deep, moist, rich soils.

DISEASES AND INSECTS: Anthracnose, leafspots, aphids, Sycamore plant bug, Sycamore tussock moth, scales, bagworms, borers, ad infinitum; anthracnose (*Gnomonia veneta*, also listed as *G. platani*) is a serious problem as it affects developing leaves and stems; there is a dieback followed by a "witches' broom" type development beneath the dead area; cool temperatures and excessive moisture are ideal for the spread of this disease.

LANDSCAPE VALUE: If native to an area do not remove the tree(s); however, do not plant it; used for street tree planting in Urbana, IL; the tree is simply too large and is constantly dropping leaves, twigs and fruits; if people only considered all the factors regarding each tree they plant perhaps much maintenance and trouble could be avoided, but . . . !; the city forester and I had several bouts over the removal of a plant that happened to be located in the tree lawn (parkway) bordering my property; I wanted to remove the tree and he did not approve; I did end up removing the lower branches; the tree was forever dropping part of its anatomy but was truly at its "best" when anthracnose kept it devoid of leaves until mid to late June; in a native situation especially along water courses it is an impressive sight in the landscape.

CULTIVARS:

'Howard' (PP 5,359)—Never knew one existed until the 1989 Georgia-South Carolina nursery meeting when a gentleman approached me about rooting a yellow-foliaged form; the new growth is a bright yellow that fades with the heat of summer; it is spectacular when the leaves first emerge; observed in Wilmington, NC at Airlie Gardens.

PROPAGATION: Supposedly no pregermination treatment is necessary, although 60 days at 41°F has proven beneficial.

ADDITIONAL NOTES: The wood is heavy, hard, tough and coarse grained, and is used for furniture, boxes, crates and butcher's blocks. A beautiful tree in its finest form and as a child growing up in Cincinnati, OH, much pleasure was derived from climbing and hiding in the hollow trunks of the magnificent specimens that occurred along the stream along the back of our property.

NATIVE HABITAT: Ranges from Maine to Ontario and Minnesota, south to Florida and Texas into northeastern Mexico. Introduced 1640.

RELATED SPECIES:

***Platanus orientalis* L.**, (plat'a-nus ôr-i-en-tā'lis), Oriental Planetree, is one of the parents of *P. xacerifolia* and mentioned here because of its resistance to anthracnose which was apparently transmitted to the London Planetree. Similar to other species except the 5- to 7-lobed, 4 to 8" wide leaves are more deeply incised, the sinuses reaching nearly to the middle of the blade, the base long cuneate or truncate. The fruits are borne 3 to 6, rarely 2's. The bark is a cream color. I have seen a magnificent specimen at Kew Gardens and one can really appreciate the beauty of the tree in its mature state. It is not common in the United States. JC Raulston Arboretum promoted a clone called 'Digitata' (also listed as f. *digitata*) with finger-like lobes. It proved susceptible to canker and leaf diseases. Definitely not superior to the better cultivars of *P. xacerifolia*. In China, hairs on fruits have been reported to cause extreme irritation to eyes, nose, ears, and throat; see *J. Arboriculture* 13:113-118 (1989). Cankerstain and powdery mildew were reported on this species. Southeastern Europe and western Asia. Zone 7 to 9. Not particularly hardy.

*Platanus orientalis*

Platanus racemosa Nutt., (plat'a-nus ra-se-mō'sa), California Sycamore, with 3- to 5-lobed, 6 to 12" wide, leathery deep green above, tomentose below leaves and fruits grouped 3 to 7. National champion is 95' by 108' at San Juan Capistrano, CA. 'Roberts' has more deeply cut sinuses and is more resistant to anthracnose; grows 50' by 40'. Native to California. Cultivated 1870. Zone 7 to 9.

Platanus wrightii S. Wats., (plat'a-nus rīt'ē-ī), Arizona Sycamore, has deeply 5- to 7-lobed leaves and fruits grouped 2 to 4. On an expedition to Tucson, AZ, one of my former graduate students and the author were plant hunting on Mt. Lemon and witnessed handsome stands of the species in the ravines leading down from the mountain. National champion is 71' by 73' in Coconino National Forest, AZ. Arizona, New Mexico to northwestern Mexico. Cultivated 1900. Zone 7 to 9.

*Platanus wrightii*

Platycarya strobilacea Sieb. & Zucc.

(plat-i-kā'ri-a strō-bil-ā'sē-a)

FAMILY: Juglandaceae

LEAVES: Alternate, compound pinnate, 7 to 15 leaflets, 6 to 12" long, each leaflet 1 3/4 to 4" long, sessile, ovate to oblong-lanceolate, acuminate, biserrate, dark green, glabrous, leaflets when crushed have fragrance like Black Walnut.

Platycarya strobilacea is a small, 20 to 30' high, round-headed tree with handsome dark green foliage and curious ovoid-oblong, 1 to 1 1/2" long, upright, cone-like catkins that persist after maturation. The flowers are monoecious with the male in 2 to 3" long, erect catkins in groups of 4 to 8. The fruit is a 1/5" diameter, winged nutlet in a $\pm 1 \frac{1}{2}$ " long, ovoid, cone-like structure. Appears to prefer a moist, well-drained soil, but has grown vigorously at the Arnold and JC Raulston Arboreta. A 40' tree at Hillier, 1999. Certainly a tree for the collector. The fruits are unique. Monotypic genus related to *Pterocarya*. China, Japan, Korea, Taiwan. Introduced 1845. Zone 6 to 8.

Podocarpus macrophyllus (Thunb.) Sweet 'Maki' — Maki, Shrubby or Chinese Podocarpus

(pō-dō-kār'pus mak-rō-fil'us)

FAMILY: Podocarpaceae

LEAVES: Arranged spirally on stem, evergreen, needle-like, 1/2 to 2 3/4" long, 1/4 to 3/8" wide, sharply acute, leathery, lustrous waxy dark green above with two wide glaucous stomatiferous bands beneath, glabrous; needles give a bottlebrush-like effect.

STEMS: Stout, green, grooved, glabrous.

SIZE: 20 to 35' high, one-half this in spread; smaller in Piedmont.

HARDINESS: Zone 8 to 10, severely injured at -3°F on Georgia campus, many plants burned at 11°F at Sea Island, GA, most probably because of cambial damage (bark split) during the 1983-84 freeze.

HABIT: Upright oval to columnar evergreen shrub or tree; quite stiff and rigid; useful for screening and hedging.

RATE: Slow.

TEXTURE: Medium-fine.

BARK: Older specimens of the species have yew-like, exfoliating, gray to red-brown bark, quite attractive but seldom evident as foliage camouflages the effect.

LEAF: Lustrous dark green throughout the seasons.

FLOWERS: Dioecious, male catkin-like, cylindrical, yellow brown, 1 to 1 1/2" long in clusters, female consists of a short stalk bearing few scales of which only the upper one or two are fertile; April-early May.

FRUIT: Naked seed, red to red-purple, 1/2" long, have seen fruits with a pronounced bloom that gave them a bluish color, attached to a fleshy receptacle generally the same color as the seed; fruits are not poisonous and can be used to make preserves.

CULTURE: Transplants readily from containers; prefers well-drained, fertile soils; like *Taxus* does not tolerate wet feet; full sun or moderate shade; tolerant of salt spray; displays excellent heat tolerance.

DISEASES AND INSECTS: Root rot in wet situations, scale has been reported and has occurred on plants in our tests.

LANDSCAPE VALUE: Makes a good hedge, screen, or small specimen tree where adapted; in upper reaches of Zone 8 is more shrubby and not particularly vigorous; used in quantity along the Georgia coast, throughout Florida, Gulf Coast and California; at The Cloisters, Sea Island, GA it is appressed to and shaped to fit against the buildings, particularly in shady environments; considered deer resistant.

CULTIVARS:

'Brodie'—Spreading, compact form, 3' high by 6' wide.

'Chollipo Form'—New growth cream-yellow, maturing green; how similar to 'Gold Crown' is unknown; witnessed at New Hanover County Arboretum in mid May and the shoots were moving toward green.

'Edgefield'—Cold-hardy selection that has performed well for 10 years in the Georgia trials; upright habit, looser than typical 'Maki', dark green leaves hold color in winter; easy to root; found by Dr. Dan Horton, UGA, in Edgefield, SC.

'Golden Crown'—Bright yellow new growth and each succeeding flush of new growth is bright yellow; introduced by Ted Stephens, Nurseries Caroliniana.

'Nana'—Bushy, rounded, compact clone.

'Pringle's Dwarf'—Compact form.

'Royal Flush'—New growth is a bright pink that slowly matures to green; 6 to 8" of each flush of growth during the growing season retains this characteristic; introduced by Ted Stephens, Nurseries Caroliniana.

'Spreading'—Spreading form, ground cover-like habit.

'Variegatus'—Cream-white to white variegated foliage.

PROPAGATION: Seeds require 2 years to germinate. Hardwood cuttings root readily, handle like *Taxus*; also can be rooted in late summer and fall, 3,000 to 8,000 ppm IBA-talc, well-drained medium, mist. Tissue culture has succeeded; see *Scientia Horticulturae* 47:323-326 (1991).

ADDITIONAL NOTES: *Podocarpus* belongs to the gymnosperms and bears a naked seed that is referred to as a "fruit." The podocarps are warm climate trees and shrubs and in northern areas are utilized as house and conservatory plants. Approximately 100 species are known and many are superb ornamentals. Even in Zone 7 (0 to 10°F, Athens, GA) they do not perform well. *Podocarpus macrophyllus* 'Maki' was grown on the Georgia campus but suffered from the low winter temperatures and perhaps poorly drained clay soil of the Piedmont.

'Maki' was listed as var. *maki* in the 1990 edition. As currently cataloged it represents more than one clone, although what I see in the trade is as described above. The species *P. macrophyllus* has larger,

broad linear-lanceolate leaves, 3 to 4" long, 2/5" wide on mature trees, often longer to 7" on young trees. It is coarser and less hardy than 'Maki'.

The Atlanta Botanical Garden, under the leadership of Ron Determann, has assembled one of the best gymnosperm collections in the Southeast, with many *Podocarpus* species either growing in the outside collection or in the greenhouse. Time will tell if they have landscape merit. All are sited in raised beds in well-drained soil. Two of the hardiest are *P. lawrencei* Hook. f. (*P. alpinus* R. Br. ex Hook. f.), Tasmanian Podocarp, and *P. nivalis* Hook., Alpine Totara. Both are listed as Zone 7 adaptable. Ted Stephens, Nurseries Caroliniana, North Augusta, SC, about 110 miles southeast of Athens, believes *P. lawrencei* has promise and noted it thrived in his nursery. Report from Yucca Do Nursery, Waller, TX indicated satisfactory performance. 'Blue Gem' is a female selection of *P. lawrencei*, a broad mound, with attractive blue-green needles. Experienced during sabbatical and was impressed with foliage color. 'Purple King' assumes a silvery-blue color with the advent of cold weather.

In Ireland and the south of England, I made the acquaintance of *P. salignus* D. Don, Willowleaf Podocarp, with graceful, slender 3 to 5" long, 1/4" wide, lustrous foliage and *P. totara* G. Benn. ex D. Don, Totara, the largest and most robust species, with yew-like, 1/2 to 1" long, 1/6" wide, sharply spined needles.

Podocarpus salignus is native to central Chile, Zone 8; *P. totara* to New Zealand, Zone 9.

NATIVE HABITAT: Japan, southern China.

RELATED SPECIES:

Nageia nagi (Thunb.) Kuntze (formerly *Podocarpus nagi* (Thunb.) Mak.), (nā-jē'a nā'jī), Broadleaf or Japanese Podocarpus, forms a loose pyramidal outline of soft pendulous branches. Ultimate height ranges from 30 to 40'. The lustrous dark green, elliptic leaves are 1 to 3" long and 1/2 to 1 1/4" wide, with numerous veins running lengthwise. This species is distinct in the width of the leaf as compared to its length. Fruits are about 1/2" wide and covered with a plum-like bloom. Bark is quite attractive. Has been utilized at Disney World with great success. Native of southern Japan, Taiwan, and China. Introduced 1830. Only suited for Zones 9 and 10. Largely killed to the ground at 11°F at Sea Island, GA.

Poliothyrsis sinensis Oliv.

(pōl-ē-ō-thēr'sis sī-nen'sis)

FAMILY: Flacourtiaceae

LEAVES: Alternate, simple, broad ovate, 3 to 6" long, acuminate, rounded or truncate, medium green, dentate, 3 prominent veins, pubescent beneath; petiole—1 to 1 1/2" long.

Poliothyrsis sinensis is not common and the first flowering plants I experienced were at the Arnold Arboretum where in late July, large, white, fragrant panicles were dripping from the ends of the shoots. This indicates that flowers are formed on the new growth of the season. Bark, gray-brown, has horizontal lenticels like cherry. Although described as a tree, 40 to 45', I envision a shrub-like constitution, 15 to 20'(25') high and wide at maturity. A 30' tall plant grew at Hillier in 1999; this specimen was just starting to flower on July 20. The foliage is rich green and turns yellow-burgundy in autumn. When first emerging, leaves are soft yellow, appearing nitrogen deficient. Flowers are monoecious, 1/3" diameter, with 5 sepals (apetalous) that initiate white and age to yellow. Fruit is a 3- to 4-valved, 1/2 to 3/4" long capsule with winged seeds. The flowers are borne in a (4")6 to 8" long, loose, terminal panicle. Does not appear aloof about soils. The Arnold's plants were in full sun and in the 1991 summer I witnessed them, the plants had persisted through an extended drought. Unusual accent, novelty, fool-your-friends plant. Wonderful article by Spongberg, *Arnoldia* 54(3):32–34 (1994), provides history, characteristics, and culture. Central China. Introduced 1908. Zone (5)6 to 7.

Poncirus trifoliata (L.) Raf. — Hardy-orange, Trifoliate-orange, Bitter-orange
(pon-sī'rus trī-fō-li-ā'ta)

FAMILY: Rutaceae

LEAVES: Alternate, trifoliate, terminal leaflet obovate to elliptic, 1 to 2 1/2" long, 1/2 to 1" wide, obtuse or emarginate, cuneate, crenulate, sub-coriaceous, the lateral ones similar, but smaller and usually elliptic-ovate, very oblique at base, lustrous dark green, glabrous; petiole—1/3 to 1" long, often winged.

BUDS: Glabrous, rather small, solitary, sessile, subglobose, with about 3 exposed scales; terminal lacking.

STEM: Glabrous, glossy green, triangular, dilated into the thorns at nodes, rather stout; pith large, white, homogeneous; leaf scars very small, elliptical, scarcely raised; bundle trace 1, crescent-shaped; no stipule scars; single spine at node, 1 to 2" long; green stem color and very prominent broad-based spines are good winter identification characters.

SIZE: 8 to 20' high, 2/3's that in width.

HARDINESS: Zone 6 is more favorable; however, will grow in Zone 5 to Zone 9; have seen it killed to ground by -20°F.

HABIT: Small, oval shrub or tree with green spiny stems, usually low-branched and viciously spiny.

RATE: Slow to medium.

TEXTURE: Medium in leaf; medium to coarse in winter.

STEM COLOR: Young stems a distinct bright green with numerous spines, almost lethal to the touch.

LEAF COLOR: Lustrous dark green in summer changing to yellow or yellow-green in fall.

FLOWERS: Perfect, white, 5-petaled, axillary, subsessile on previous year's branches, 1 1/2 to 2" across, supposedly very fragrant, borne singly usually in late April to early May; in Athens, flowers appear on naked stems in late March—early April; in spite of what the literature states I cannot sense the sweet odor.

FRUIT: A modified berry (hesperidium), yellow, 1 1/2" across, covered with soft down or glabrous, containing numerous seeds, very sour, ripening in September or October; ripens an unbelievable quantity of fruits in the South.

CULTURE: Easy to transplant, prefers well-drained, acid soils; once established in the right situation it proves to be a vigorous grower; full sun; has escaped from cultivation near Wrightsville, GA and in the Houston, TX area, fields have been colonized; also at Jefferson's Monticello, plants occasionally dot the local woods; several old plants grow in the cemetery where Jefferson is buried and serve as the inoculum for the wayward souls (no pun intended).

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: More of a novelty plant than anything else in the North, used in the South for hedging because of its dense growth and thorny character; no sane person would attempt to penetrate this hedge! At one time I doubted its landscape usefulness but have seen plants in Longwood's Mediterranean garden with yucca, prickly pear, sedum, and blue sheep's fescue that appeared to belong; the plant has tremendous late fall and winter character because of yellow fruits and interesting green stems and spines; spines are lethal and, doubtfully, should be used in high traffic areas; visited Oklahoma State University campus and noticed the plant was used as a hedge; hedges were so tightly pruned that one could walk on top; could prove more effective than a good watch dog.

CULTIVARS:

'Flying Dragon'—Interesting twisted stems, a novelty at best; has been embraced for accent use; spines also have a slight twist; I never believed Don Shadow when he told me this cultivar had a future; grows as large as the species, truly a quirky habit, seedlings come true-to-type as the embryos are nucellar in origin from 2n tissue (like the parent) and not sexual via male and female gametes; seedlings first emerge and appear "normal", with time and size the spiraling stem character is evident; have grown hundreds of seedlings and, as I reflect, all were twisted.

New cultivars are being introduced from Japan. Have observed a dwarf 'Flying Dragon' and a variegated 'Flying Dragon' with cream marked leaves, irregularly presented; only a demented collector would covet such a "thing".

PROPAGATION: Seeds germinate like beans when stratified for 90 days at 41°F in a moist medium; one of my former students collected fruits from a tree in the Missouri Botanic Garden, St. Louis, and after stratification subsequent germination averaged 95% plus. I have also collected fruits in October from the University's

Botanical Garden and sowed them directly, initial germination took 4 to 6 weeks and seeds were still coming up 3 months later; the cold period unifies and hastens germination more than anything else; also noted quite a number of albino seedlings, many more than occur in most seedling populations. Softwood cuttings taken in summer rooted after treatment with 50 ppm IBA/17 to 24 hour soak; cuttings taken in late October failed to root without treatment, but rooted 76% after treatment with 50 ppm NAA/24 hour soak. Species rooted 58% after treatment with 4,000 ppm IBA; 'Flying Dragon' 100% with 2,000 ppm IBA; 'Rubidoux' 44% with 6,000 ppm IBA.

ADDITIONAL NOTES: Introduced into commerce in U.S. by William Saunders of the USDA and P.J. Berckmans of Augusta, GA. It was listed by the Prince Nursery in 1823. Ripe fruits set aside for several weeks become juicy and develop a sprightly, slightly acid flavor. Serves as a substitute for lemon, pulp—can be made into marmalade, and peel can be candied. After removing the numerous seeds there is not a whole lot of pulp left over. Want to emphasize that the most respected reference books describe the flowers as sweetly scented. I may be missing something but have smelled flowers from numerous plants and cannot sense the "sweet perfume".

NATIVE HABITAT: Northern China, Korea. Introduced about 1850. Seems incongruous that Prince Nursery listed it in 1823 but its introduction date corresponds to about 1850. Such is the nature of the literature.

Populus alba L. — White Poplar, Silver-leaved Poplar

(pop'ū-lus āl'ba)

FAMILY: Salicaceae

LEAVES: Alternate, simple, on long shoots, palmately 3- to 5-lobed with triangular, coarsely toothed lobes, acute, subcordate or rounded at base, 2 to 5" long, dark green above, white-tomentose beneath; on short branches, smaller, 1 to 2" long, ovate to elliptic-oblong, sinuate-dentate, usually gray tomentose beneath; petiole—1/2 to 1 1/2" long, tomentose.

BUDS: Imbricate, small, ovate to conical, light chestnut brown, appressed, shining or more or less covered especially toward base with cottony wool; laterals 1/5 to 1/4" long, terminals larger.

STEM: Slender or sometimes stout, greenish gray, densely covered with thick whitish cottony wool which can be readily rubbed off; pith—5-pointed, star-shaped.

BARK: On young trunks characteristically light greenish gray or whitish, often with dark blotches; base of older trunk deeply furrowed into firm dark ridges.

SIZE: 40 to 70' in height with a similar spread; can grow to 90' or greater; national champion is 68' by 70' in Charlevoix, MI.

HARDINESS: Zone 3 to 8(9).

HABIT: Usually a wide-spreading tree with an irregular, broad, round-topped crown; at times spreading abundantly by root suckers; tends to be weak-wooded and susceptible to breakage in storms.

TEXTURE: Medium-coarse in leaf; coarse in winter.

BARK: Greenish gray to whitish, marked with darker blotches, the bases of old trunks becoming fissured, with blackish ridges.

LEAF COLOR: Dark green above and silvery white beneath, the lower surface coated with a thick, matted tomentum; the leaves fall very early in the fall and usually show no coloration although yellowish and reddish have been listed by various authorities.

FLOWERS: Dioecious; male catkins 2 to 3" long, 5 to 10 stamens per flower, anthers purple, female 3 to 4" long.

FRUITS: Two-valved, dehiscent capsule.

CULTURE: Easy to grow, does well under any conditions but prefers moist, deep loam; pH adaptable; full sun; prune in summer or fall as it "bleeds" if pruned in winter and spring; air pollution tolerant; quite tolerant of salt spray.

DISEASES AND INSECTS: Poplars, in general, are affected by a whole host of diseases; they are poor ornamental trees and are continually dropping leaves, twigs and other debris; the following pests are the more common and include *Cytospora* canker, poplar canker, fusarium canker, hypoxylon canker, septoria

canker, branch gall, leaf blister, leaf spots, leaf rusts, powdery mildew, dieback, aphids, bronze birch borer, poplar borer, red-humped caterpillar, poplar tent maker, scales and imported willow leaf beetle; if anyone plants poplars they deserve the disasters which automatically ensue.

LANDSCAPE VALUE: I hesitate to recommend this tree for anyone since it becomes a nuisance and liability after a time; wood is brittle, roots will clog drain tiles, sewers and water channels; avoid this pest; there are those who admire the silver-backed leaves and white bark, be cognizant that leaves may abscise by late summer due to fungal leaf spots.

CULTIVARS:

'Globosa'—Broad-rounded habit, large shrub-like constitution; young leaves pinkish, gray-tomentose below.

'Intertexta'—Leaves dull gray, developing yellow speckles with maturity.

'Nivea'—Stems, leaf undersides and petioles are white tomentose, leaves prominently lobed, considered a juvenile characteristic which is reduced as plant matures.

'Pyramidalis'—Columnar in habit; called Bolleana Poplar; better than Lombardy Poplar but still of negligible quality; slightly broader than Lombardy; several mature trees at the Morton Arboretum were 60' by 9' and 55' by 5', all diseased and declining.

'Raket'—Described as narrow habit with upright branches; have not observed.

'Richardii'—Upper surface of the leaves yellow, white beneath; slow-growing, effective from a distance; have seen a time or two and always wanted to fertilize the tree; sometimes treated as a cut-back shrub to encourage long shoots of better color and intensity; an old specimen at the Morton Arboretum was 72' high.

PROPAGATION: Seed requires no pretreatment and germination will take place after dispersal. Cuttings root when treated with IBA but success may vary with timing; probably best in July–August.

ADDITIONAL NOTES: Some 30 to 35 species are known in the northern hemisphere with many hybrids occurring naturally. All are fast-growing, disease-ridden and with minimal redeeming everyday landscape value, particularly in American gardens. Ask yourself the last time a handsome poplar was seen in a cultivated situation. Possibly for naturalizing in rough areas. Few trees more impressive than *P. tremuloides* in yellow fall color. For windbreaks and quick screens, poplars might be considered. In Europe, *P. xjackii* 'Aurora' and *P. nigra* 'Italica' are as common as *Pyrus calleryana* 'Bradford' in the United States. For the average site in the United States, there are many superior tree selections.

For lack of a clear-cut pigeon hole, I offer 4 additional patented (and unpatented) *Populus* taxa.

'Curly Poplar' (PP 17,525)—Hybrid of *P. canescens* × *P. alba* that occurred as a sport on a cultivated tree in Maryland; the tree produces high value, curly figured veneer.

'Gnarly Poplar' (PP 15,613)—Hybrid of *P. trichocarpa* × *P. maximowiczii* with contorted, zig-zagging branches and trunk undulations.

'Shinsei' (PP 14,664)—Hybrid of *P. nigra* × *P. maximowiczii* with narrow crown form, dark green foliage, high resistance to leaf rusts and anthracnose, and low palatability to possums; I was unsure about that last statement but it was included in the patent abstract; this was a first!

'Highland'—Similar to *P. acuminata* with smaller, waxy dark green leaves; disease resistant; seedless; 40 to 50' by 20 to 25', upright oval habit; introduced by Highland Nursery, Greeley, CO; tested at Milliken Arboretum, Spartanburg, SC with essentially total leaf drop by late summer.

NATIVE HABITAT: Central to southern Europe to western Siberia and central Asia. Long cultivated. Naturalized in North America. Introduced 1784.

RELATED SPECIES:

***Populus nigra* L. 'Italica'** — Lombardy Black Poplar, Lombardy Poplar, Italian Poplar
(pop'ū-lus nī'gra)

LEAVES: Alternate, simple, rhombic-ovate, triangular, 2 to 4" long, about as wide, long-acuminate, broad cuneate to truncate, finely crenate-serrate, non-ciliate, dark green above, glabrous, light green beneath; petiole—3/4 to 2 1/4" long, slender, flattened.

BUDS: Imbricate, small compared to other poplars, terminal 3/8" long, laterals 1/3" or less long, appressed, shiny, glutinous, reddish brown, glabrous.

STEM: Slender, round, lustrous brown.

GROWTH HABIT: Easily recognizable because of decidedly upright habit; often used for screens on old farm properties.

Populus nigra 'Italica', Lombardy Black Poplar, is an upright, fast-growing cultivar that was introduced into this country in colonial times (1784). Can grow to 70 to 90' with a spread of 10 to 15' in 20 to 30 years but seldom attains this size because of a canker disease which develops in the upper branches and trunk for which there is no cure. In the Morton Arboretum trees are 50' by 14' and 44' by 8'. Substitutes might include *Populus alba* 'Pyramidalis', *Alnus glutinosa* 'Fastigiata', *Quercus robur* 'Fastigiata', although none will grow

as fast as Lombardy. Lombardy is a male clone and is propagated by cuttings. The catkins are 1 to 2" long, with 12 to 20 stamens per flower, the anthers crimson. It apparently arose in the Lombardy district of Italy in the 1600's and was spread to other parts of Europe in the early 1700's. *Cryptodiaporthe* (*Dothichiza*) *populea* canker is a devastating disease which starts in the upper branches of the tree. It also infects Balsam, Black, and Eastern Cottonwoods. A form listed as 'Thevestina' ('Theves') and sold as an improved Lombardy does resemble Lombardy in habit but tends to be more broad, has a whitish bark that becomes dark and slightly furrowed on old trunks, and is a female clone. A more correct name is 'Afghanica' for this form arose by mutation from a race of *P. nigra* native to central Asia. A 60' by 9' tree grew in the Morton Arboretum. It is supposedly more resistant to the canker but I have seen no hard evidence to support this claim. 'Lombardy Gold', as I have seen it in Europe, is similar to Lombardy in growth habit but has yellow-gold leaves; selected in 1974 as a sport of Lombardy Poplar. 'Majestic' is a hybrid, fast-growing, pyramidal, male, with greater resistance to diseases, from University of Wisconsin. Other cultivars include: 'Charkowiensis', 'Gigantea', 'Plantierensis', 'Vereeken', and 'Vert de Garonne', with variations on the upright growth habit of Lombardy are described in European literature. I have not observed them in the United States. See Wood, *Arnoldia* 54:24–30 (1994) for the history of 'Italica' in North America. Madsen, *Arnoldia* 54:31–34 (1994), offers fastigate alternatives to the above. The species is native to western Europe, North Africa, Russia. Lombardy is adapted to Zones 3 to 9.

Populus deltoides Bartr. ex Marshall — Eastern Cottonwood, also called Eastern Poplar.
(pop'ū-lus del-toy'dēz)

FAMILY: Salicaceae

LEAVES: Alternate, simple, deltoid-ovate or broad-ovate, 3 to 5" (6") long, about as wide, acuminate, subcordate to truncate and with 2 or 3 glands at base, coarsely crenate-dentate with curved teeth, entire at base and apex, densely ciliate, medium green above, bright green below, glabrous; petiole—2 1/2 to 4" long, flattened laterally.

BUDS: Imbricate, terminal—1/2 to 3/4" long, 6 to 7 visible scales, conical, acute, shiny chestnut brown, resinous, balsam scented; laterals—more or less flattened, appressed, smaller.

STEM: Stout, yellowish to greenish yellow to brown, round or marked especially on vigorous trees with more or less prominent wings (decurent ridges) running down from the two sides and bases of the leaf scars; also quite ragged in appearance.

SIZE: 75 to 100' in height spreading 50 to 75'; national champion is 154' by 84' in Buffalo County, WI; var. *occidentalis* national champion is 95' by 98' in Hygiene, CO.

HARDINESS: Zone 3 to 9.

HABIT: Pyramidal in youth but developing a broad vase-shaped habit in old age with the branching structure being somewhat open, irregular and ragged; often with massive, spreading branches.

RATE: Fast, 4 to 5' a year in rich moist soil is not uncommon, in fact, in two years trees may attain heights of 30' and diameters of nearly 5".

TEXTURE: Medium-coarse in leaf, coarse in winter.

BARK: Ash-gray and divided into thick, flattened or rounded ridges separated by deep fissures on old trunks; young stems and trunks greenish yellow; impressive bark on mature trees.

LEAF COLOR: Lustrous light to medium green in summer, abscising early in fall and usually with a trace of yellow; in some regions good yellow.

FLOWERS: Applies to most *Populus*; dioecious, anemophilous, in pendulous catkins appearing before the leaves, individual

flowers (both sexes) solitary, inserted on a disk and subtended by a bract; male flowers with either 6 to 12, or 12 to many stamens; female with a single pistil; up to 60 stamens on *P. deltoides* with attractive red anthers; usually opening in March–April before the leaves.

FRUIT: Three- to 4-valved dehiscent capsule, 1/4 to 1/3" long, the seeds are tufted and represent the "cottony" mass which is seen under and around the trees at dispersal time, June–July; hence, the name Cottonwood.

CULTURE: Easily transplanted and grown, prefers moist situations along waterways but tolerates dry soils; very common on moist alluvial soils through the plains and prairie states; tolerates saline conditions and pollutants; very pH adaptable; considered a short-lived species and trees over 70-years-old deteriorate rapidly; however, I have observed noble, stately, awe-inspiring specimens, particularly in the Midwest.

DISEASES AND INSECTS: See under *P. alba*; serious leaf and canker problems with this species and the many hybrids, resistance has been illusive.

LANDSCAPE VALUE: Little, except in the difficult plains states; a messy tree often dropping leaves, flowers, fruits, twigs and branches; will break up in storms as the wood is light, soft and weak; impressive in river bottoms and should remain there; quite weed-like and stray seedlings are evident in fields alongside water courses where the tree grows naturally, quick to move into abandoned land.

CULTIVARS: Many cottonless (male) forms and hybrids between *P. deltoides* and *P. nigra* have been selected and named. Pair evaluated six different forms over a 10-year period.

'Colmar'—Resistant to leaf diseases; male; yellow fall color; from University of Illinois.

'Lydick'—Averaged 4' per year; female clone.

'Mighty Moe'—Seedless, oval-shaped tree; green summer foliage turns yellow in fall; smooth bark; good tree for plains and prairie states; 65' by 40'.

'NE-355'—Averaged 3' per year.

'Noreaster'—Averaged 4' per year; hybrid, with thicker bark and canker resistance.

'Red Caudina'—Narrow pyramidal form 50 to 70' by 8 to 12'; large deltoid leaves with red veins and petioles, young leaves are bronze-red; male.

'Robusta'—Averaged 4'1" per year, vigorous; developed some canker; 40 to 60' by 30 to 40'.

'Siouxland'—Averaged 2'10" per year; rust resistant; male form; introduced by South Dakota State University; apparently is susceptible to canker after 18 to 20 years; have observed in Spring Grove where ~10-year-old trees averaged 30' high and were quite pyramidal in outline, had dropped many interior leaves by late August and were not the most appealing specimens; included at Milliken Arboretum, Spartanburg, SC and leaves are essentially absent by September; estimated size 60 to 80' by 30 to 40'.

'Skywalker'—Narrow form from Nebraska; a 10" diameter tree undamaged in 2009 devastating ice storm in Louisville, KY; according to Mike Hayman who compiled damage assessments, the species also held up well.

'Sparks'—Narrow version of the cottonless cottonwood, 40' by 15'; discovered near Sparks, Nebraska.

Species Male Clone—Averaged 3'4" per year; subject to breakage.

PROPAGATION: Seeds require no pretreatment; cuttings can also be used and apparently root with varying degrees of ease depending on the tree from which they were selected.

NATIVE HABITAT: Quebec to North Dakota, Kansas, Texas; Florida. Introduced 1750.

OTHER *POPULUS* OF GENERAL INTEREST

There are about 30 to 35 species of poplars widely distributed in North America, Europe, North Africa and in Asia south to the Himalayas. There are numerous hybrids and named cultivars. In European countries they are commonly used for streets, parks, fence row, windbreak and canal plantings. They are important sources of pulpwood and other wood products. Their growth rates are phenomenal and the following figures are derived from information put out by the Minnesota Landscape Arboretum. Bolleana Poplar grew about 30' in 9 years; 'Siouxland' 40' in 9 years; Japanese Poplar 30' in 9 years; *Populus nigra* 'Afghanica' ('Thevestina') 30' in 9

years; *P. tremula* 'Erecta' 30' high and 4' wide in 10 years; *P. tremuloides* 25' in 10 years; *P. trichocarpa* 20' high and 7' wide in 9 years.

Poplars can be divided into four groups:

1. White and gray poplars, aspens.

Young trunks and main branches at first smooth, eventually pitted with numerous diamond-shaped holes; leaves toothed or lobed; they can be further subdivided into:

White or gray poplars—Leaves on long shoots woolly beneath, those of short shoots less woolly or almost glabrous, and of different shape; petioles usually not flattened; included here are: *P. alba*, *P. xcanescens* (Ait.) Small, and *P. xtomentosa* Carr.

Aspens—Leaves glabrous or almost so beneath; uniform in size and with laterally flattened petioles which allow them to flutter in the slightest breeze; included are: *P. grandidentata*, *P. tremula*, and *P. tremuloides*.

2. Leucoides

The leaves are large and leathery, usually tomentose when young, and more or less the same size and shape; the bark is rough and scaly; *P. heterophylla* L., *P. lasiocarpa* Oliv., and *P. wilsonii* C.K. Schneid. belong here.

3. Balsam poplars

The first to open in the spring, the buds and leaves very gummy, emit a pleasant balsam fragrance when expanding; usually whitish but not woolly beneath; petiole not compressed; *P. angustifolia* E. James ex. Torr., *P. balsamifera* L., *P. laurifolia* Ledeb., *P. maximowiczii* Henry, *P. simonii* Carr., *P. trichocarpa* Hook. (now a variety of *P. balsamifera*) and others belong here.

4. Black poplars

Leaves are green on both sides, petioles compressed, margins translucent and cartilaginous, trunks ridged-and-furrowed; *P. deltoides*, *P. nigra*, and others belong here.

Populus xcanadensis Moench — Carolina Poplar

(pop'ū-lus kan-a-den'sis)

Populus xcanadensis represents a large group of hybrids between *P. deltoides* and *P. nigra*. They are more vigorous than either parent and propagate easily from cuttings. 'Eugenei' is of a columnar habit with comparatively short, spreading lateral branches. 'Prairie Sky' is a tall, narrow single-stemmed, male tree with short lateral branches, parent tree was 33' high, 6 1/2' wide, triangular-shaped leaves, approximately 4" long and 4" wide with a shiny green upper surface, exhibited high resistance to canker and only minor susceptibility to leaf rust diseases, from Morden, Manitoba, Canada. 'Carrièreana', 'Eugenei', 'Florence Biondi', 'Gelrica', 'Henryana', 'Marilandica', 'Noreaster' (only hybrid to show resistance in Dr. Pair's Wichita trials), 'Pacheri', 'Regenerata', 'Robusta' (small, vigorous, broad-oval), 'Serotina', 'Serotina Aurea', and 'Serotina de Selys' belong here. Considered adaptable to Zone 4 and south. For a complete description see Bean.

Populus grandidentata Michx. — Bigtooth Aspen

(pop'ū-lus gran-di-den-tā'ta)

LEAVES: Alternate, simple, on long shoots, 3 to 4" long, about as wide, acuminate, truncate to broad-cuneate at base, coarsely sinuate dentate with callous mucronate teeth, dark green above, gray tomentose beneath at first, soon glabrescent and glaucescent, those of short branches elliptic, with sharper teeth; petiole—glabrescent, 1 to 2 1/2" long, slender, compressed toward the top.

BUDS: Imbricate, 1/8 to 1/4" long, 6 to 7 visible scales, ovate to conical, pointed, generally divergent, dull, dusty-looking due to fine, close, pale pubescence especially at margin of scales.

STEM: Stout, round, reddish brown or somewhat yellowish brown, older stems greenish gray.

Populus grandidentata is normally a medium-sized tree reaching 50 to 70', with a spread of 20 to 40'. National champion is 93' by 51' in Appleton, ME. Often pyramidal in youth with a central leader, developing an oval, open, irregular

crown at maturity. Very fast-growing (65' in 20 years). Reaches best development on moist, fertile soils but will grow on dry, sandy or gravelly soils. Ornamental assets are few but it is valuable for pulp wood and other wood uses. New leaves silver-gray, conduplicate (folded along midrib) when young; leaves emerging May 28, 2005, Deer Isle, ME. Have seen good yellow fall color in early October in Cushing, ME. Native from Nova Scotia to Ontario and Minnesota south to North Carolina, Tennessee, Illinois and Iowa. Introduced 1772. Zone 3 to 5(6).

Populus ×jackii Sarg. (*P. ×candicans* 'Aurora')

(pop'ū-lus jak'ē-ī)

Populus ×jackii represents hybrids between *P. balsamifera* and *P. deltoides*. Leaves range from 1 to 5" long, are deltoid-ovate, blue-green, with 1 to 2" long petioles. Trees vary in size from 30 to 100'. Although not common in commerce in the United States, 'Aurora' is everywhere in Europe, particularly Ireland, where the bold variegated rose, pink, cream new shoots are striking. The tree is usually cut back to induce long, supple, brightly colored shoots. The hybrid occurs in central and eastern North America. Introduced 1900. Zone 2 to 5.

Populus maximowiczii Henry — Japanese Poplar

(pop'ū-lus max-sim-ō-wix'ē-ī)

Populus maximowiczii is a handsome, rather broad-spreading, large tree. The bark is smooth, light gray-green and attractive. It has proven to be one of the most promising and disease-free poplars in Minnesota's collection. The leaves open early in spring and persist late in fall. The leaves are slightly leathery, vivid green, pale green beneath, and about 3 to 5" long and wide. It has hybridized with other species and produced named selections including 'Androskoggin', 'Geneva', 'Oxford' and 'Rochester'. Northeast Asia, Japan. Introduction before 1890. Zone 3 to ?

Populus simonii Carr. — Simon Poplar

(pop'ū-lus sī-mōn'ē-ī)

LEAVES: Alternate, simple, rhombic-elliptic, 2 to 5" long, 1 to 3" wide, acute, broad-cuneate to narrowly rounded, crenate, bright green above, pale beneath; petiole—1/3 to 3/4" long, red.

Populus simonii is occasionally grown in the northern United States, with major sitings at the Chicago Botanic Garden and University of Maine. The species is a medium to large, 40 to 60' high tree with vase-shaped habit. Unfortunately, the leaves, like many poplars, are susceptible to leaf spot and abscise prematurely. 'Fastigiata' has steeply ascending branches resulting in a rather columnar tree in youth, becoming fatter with age. Northern China. Introduced 1862. Zone 2 to 5.

Populus tremula L. 'Erecta' — Upright European Aspen

(pop'ū-lus trem'ū-la)

LEAVES: Alternate, simple, thin, suborbicular to ovate, 1 to 3" long, rounded or acute at apex, truncate or subcordate at base, margins undulate, sinuately crenate-dentate, tomentose when emerging, quickly glabrous, dark green above, glaucescent beneath, gray-green; petiole—flattened, glabrous, often as long as the blade.

Populus tremula 'Erecta' is an excellent, narrowly fastigiate tree that was found in the forests of Sweden. Originally I considered it a substitute for the canker-infested Lombardy Poplar. Based on evaluations of plants in the Illinois trials, the leaves contract a severe leaf spot and defoliated by early August. Specimens at the Minnesota Landscape Arboretum and Arnold Arboretum appeared in outstanding condition. A 40' high tree is about 6 to 8' wide at the Schmidt Arboretum, Oregon. Full complement of dark green leaves in late August 2005. 'Pendula' is a weeping form with stiffly pendulous branches

and grayish purple catkins. The tree is best adapted to colder climates. *Populus ×canescens* embodies hybrids between *P. alba* and *P. tremula*. 'Pyramidalis' and 'Tower' are upright forms, the latter almost columnar, resistant to stem cankers, and adapted to stresses of northern great plains, Morden introduction. The species is native to Europe, northern Africa, western Asia and Siberia. Zone 2 to 5.

Populus tremuloides Michx. — Quaking Aspen

(pop'ū-lus trem-ū-loy'dēz)

LEAVES: Alternate, simple, thin, ovate to orbicular, short-acuminate, truncate to broad-cuneate at base, 1 1/2 to 3" long and wide, finely glandular-serrate, lustrous dark green above, glabrous and glaucescent beneath, leaves of suckers ovate, large, glabrous; petiole—1 to 2 1/2" long, slender, flattened.

BUDS: Terminal-imbricate, conical, sharp-pointed, sometimes very slightly resinous, 6- to 7-scaled, reddish brown; laterals-incurved, similar to terminal but smaller.

STEM: Slender, lustrous, reddish brown.

BARK: Smooth, greenish white to cream-colored; in old age furrowed, dark brown or gray, roughened by numerous wart-like excrescences.

Populus tremuloides is the most widely distributed tree of North America. It is fast-growing, relatively short-lived and attains heights of 40 to 50' with a spread of 20 to 30'. National champion is 130' by 36' in Coronado National Forest, AZ. Pyramidal and narrow when young, usually with a long trunk and narrow, rounded crown at maturity. Indifferent as to soil conditions and over its range can be found in moist, loamy sands to shallow rocky soils and clay. The leaves flutter in the slightest breeze; hence, the name Quaking Aspen. The fall color is a good yellow. Ornamentally not important because of disease and insect problems but, nonetheless, an interesting tree. The wood is important for pulpwood and other uses. Have seen a rather pretty cream-yellow-margined-leaf form at Bailey Nurseries in 2005. Observed several accessions at J. Frank Schmidt & Son Nursery in August 2007 and, Keith Warren, horticulturist, pointed out the shepherd's crook dieback on the terminal shoots. Prairie Gold® ('NE Arb') is an oval to pyramidal selection, well adapted to the heat, humidity and drought of the Great Plains; resistant to leaf spot; golden fall color; 35' by 15'; introduced in cooperation with Schmidt, Nebraska Arboretum and Todd Faller (per Oregon Pride Nurseries), 2008 Great Plants release. Native from Labrador to Alaska, south to Pennsylvania, Missouri, northern Mexico and lower California. Introduced 1812. Zone 1 to 6(7). Have seen a population in the Piedmont of Georgia.

Potentilla fruticosa L. (according to GRIN, the name is *Dasiphora fruticosa* (L.) Rybd.; this change will not be totally adopted in my lifetime; RHS Plant Finder 2008–2009 keeps *P. fruticosa*) — Bush Cinquefoil
(pō-ten-til'a frō-ti-kō'sa)

FAMILY: Rosaceae

LEAVES: Alternate, compound pinnate, elliptic to linear-oblong, 3 to 7 leaflets, usually 5, 1/2 to 1" long, sessile, acute, with revolute margin, light medium blue to dark green, sometimes lustrous, more or less silky.

STEMS: Shiny brown, slender, wispy, exfoliating with age.

SIZE: 1 to 4' in height and 2 to 4' or larger in spread; dainty in size considerations.

HARDINESS: Zone 2 to 6(7), does not perform well in Zone 7; have tested several selections with no long-term success.

HABIT: Very bushy shrub with upright slender stems forming a low, rounded to broad-rounded outline.

RATE: Slow.

TEXTURE: Fine in leaf, medium-fine in winter; refined, graceful appearance in foliage.

STEM COLOR: Interesting in winter if framed by a new snow; peeling, shredding, brown in color.

LEAF COLOR: Leafs out early in spring, silky gray-green when unfolding changing to bright to dark green in mature leaf; fall color is green to yellow-brown, not ornamental.

FLOWERS: Perfect, bright buttercup yellow, about 1 to 1 1/2" across, June through until frost, borne singly or in few-flowered cymes, excellent color addition to any garden; numerous cultivars provide interesting color variation; collection at Minnesota Landscape Arboretum was in full flower on July 20, 2005, July 15, 2008.

FRUIT: Achene, not showy, persistent.

CULTURE: Fibrous rooted, transplants well, of easy culture; withstands poor, dry soils and extreme cold; full sun for best flower although does well in partial shade; best in a fertile, moist, well-drained soil; most plants are container-grown; in the wild occasionally found in bogs but more common on wet or dry open ground especially that of calcareous origin; this is one of the reasons they perform so well in the midwestern states; remove one-third of the canes or renewal prune in late winter.

DISEASES AND INSECTS: Relatively free from insect and disease pests; there are several leaf spots and mildews which affect the plant but they are rarely serious; spider mites can be troublesome.

LANDSCAPE VALUE: Shrub border, massing, edging plant, low hedge, perennial border, facer plant, can be integrated into the foundation planting and will add a degree of color unattainable with most plants, dainty clean foliage, good flower color and length of flowering period justify wider landscape consideration; can become ragged with time and proper pruning practices should be employed; I tried to grow 'Goldfinger' in my Georgia garden but the plant lacked vigor and never measured up to performance in Zone 4 to 6; high night temperatures may be the limiting factor; know many gardeners who tried to grow the various cultivars in Zone 7 without success; as mentioned, not the best-for-wear after flowering and plants become untidy, tired and deflated. Something akin to a compact spiraea might be a better choice in high profile areas.

CULTIVARS: I am hedging on my responsibility by including all the cultivars together but for ease of presentation have chosen this approach. Cultivars have been selected from several species, *P. arbuscula* D. Don, *P. davurica* Nestl., *P. fruticosa*, and *P. parvifolia* Fisch. ex Lehm. as well as from hybrids between these. All are now in the genus *Dasiphora*. Excellent review of "The Shrubby Potentillas," appeared in *The Plantsman* 9(2):90–109 (1987). Article discusses culture, taxonomy, and cultivars. Since the 1983 edition, I have seen many new cultivars come onto the market, some good, others miserable. In addition, during sabbatical I carefully evaluated the entire collection at the Arnold Arboretum. Also, Bachtell and Hasselkus. *American Nurseryman* 153(3): 83–89 reported on their evaluations of *Potentilla* cultivars. Also used Bressingham Gardens catalog as a source for new introductions and consulted Krüssmann and Hillier (2002) for more specifics. All of this information has been distilled and is presented here as a rather heterogeneous average that should serve as a reasonable guide to the selection of the best types.

Interestingly, *The New RHS Dictionary of Gardening* treats *P. fruticosa* as a polymorphic species and reduces the above species to varieties. In practice, it might be wise to consider all under the genetic umbrella of *P. fruticosa*. Cultivars exceed 150 and new additions, particularly from Europe and Canada, occur yearly. The fifth edition discussed 81 cultivars; this edition adds 33 more. I counted another 24 cultivars in Hillier 2002 that are not listed herein. Over 100 listed as commercially available in the RHS Plant Finder 2008–2009. RHS Trials Bulletin lists another 18 different cultivars. Show me the best white, yellow, pink, orange and red and let's move on.

'Abbotswood'—Dark bluish green foliage, spreading habit, large white flowers produced over a long period; considered one of the best whites, truly outstanding in flower; 3' high, 3' wide.

'Abbotswood Silver'—Leaves with creamy white margins; the entire shrub rather handsome on close inspection; does not appear to be a vigorous grower and is not preferable to 'Abbotswood'; flowers are white; probably only good in cooler climates; 24 to 30" by 24 to 30".

'Annette'—Orange-yellow flowers, flowers fade in high heat; compact dome shape; relatively new from Europe.

'Apricot Whisper'—Apricot flowers, light green foliage, oval-rounded habit, 2 to 3' high; University of Manitoba introduction.

'Barnbannoch'—Strong bushy constitution, a continuum of primrose yellow flowers, 30 to 36" high.

'Beanii'—White flowers, shiny dark green leaves, medium height, irregular rounded form, severe dieback at –19°F.

'Beesii'—Buttercup yellow, 3/4" diameter flowers; producing stamens only (should be fruitless); leaves rather silvery green; slow-growing to 2' high.

'Boskoop Red'—Flame red flowers early in season becoming lighter later; bright green foliage on a semi-dwarf plant.

'Buttercup'—Deep yellow, 1" wide flowers; pale green leaves; low, mounded, fine-textured form; severe dieback at –19°F.

'Coronation Triumph'—A large clone, 3 to 4', with a softer green foliage cast compared to 'Jackmanii'; the habit is dense, full, and mounded, and the bright yellow 1" diameter flowers are borne in great quantity; Drs. Jim Klett, Colorado State University and Dale Hermann, North Dakota State University voted it one of the best for their area; in my Illinois garden it outperformed 'Jackmanii'.

- Dakota Goldrush™ ('Absaraka')—Comparable to 'Jackmanii', possibly more compact; golden yellow, 1 to 1 1/2" wide flowers, flowers more profusely, especially late in season; 3 to 3 1/2' by 4 to 5'; dark green foliage; North Dakota State University introduction.
- 'Dakota Sunrise'—Tends toward prostrate habit the first year, eventually dense and rounded; 1" diameter, bright yellow flowers from June until frost; 2 to 3'; considered hardy to Zone 2; introduced in 1978.
- Dakota Sunspot® ('Fargo')—Vivid yellow (deep golden), 1" diameter flowers, spring to frost; compact-spreading habit, 2 to 3' high, 3 to 4' wide; North Dakota State University introduction.
- 'Dart's Golddigger'—A low-spreading form with large golden flowers, raised in Darthuizer Nurseries, Holland.
- 'Daydawn' ('Day Dawn')—Handsome form in a cool climate, peach-pink, suffused with cream, flowers fade in heat to cream; tall mounded form with medium green leaves, 30" high; sport of 'Tangerine'.
- 'Donard Gold'—Low-spreading form, perhaps 20" high but much wider; green foliage, large golden yellow flowers.
- 'Elizabeth' ('Arbuscula', 'Sutters Gold')—Flowers rich, soft yellow and up to 1 1/2" diameter, flowering over a long period, leaves somewhat grayish green; bushy shrub to 3'; I have always liked this form; described in English literature as susceptible to mildew and mites.
- 'Farreri' ('Gold Drop')—Flowers deep yellow, 3/4 to 1" diameter; leaves very small; 25-year-old plant-2' tall and 3' across; small bright green leaves, moderate flowering at Arnold.
- 'Farreri Prostrata'—Buttercup yellow, 1 1/4" diameter flowers on a 1 1/2' by 3' shrub.
- 'Floppy Disc'—Deep pink, double flowers, long flower period, may fade in heat; low-spreading habit, 10 to 18" high.
- 'Forever Gold'—Long flowering from May to October, golden-yellow flowers, bright green foliage, 2 1/2' to 3' high, 2 to 2 1/2' wide; from Fort Collins Nursery, Colorado; as I witnessed the plant in July in Minnesota, more upright branched than most cultivars and flowers more yellow than gold; a breakthrough in potentilla if the flowering period is as long as marketed; listed as a selection of var. *purdomi*.
- 'Forrestii'—Medium yellow, large flowers, most abundant in late summer; gray-green leaves, coarse texture; low, mounded form; foliage may become bronzed and chlorotic in late summer.
- 'Friedrichsenii' ('Berlin Beauty')—Flowers creamy white to pale yellow, 1" diameter; 58-year-old plant was 4 1/2' high and 6' across (hybrid origin); sparse flowered at Arnold; resembles 'Maanelys' but is more open; from a grex (group) of several clones.
- Frosty® ('Monsidh', PP 10,987)—Low spreading, mounded habit, 1' by 3'; gray-green foliage; white flowers; observed at Minnesota Landscape Arboretum, 'McKay's White' was superior on the July 20, 2005 visit, but larger growing; introduced by Sidhu and Sons Nursery, Canada.
- 'Gold Carpet'—Improved form of 'Arbuscula', mildew-free with large deep yellow flowers.
- 'Gold Drop'—Often a common name for the yellow-flowered potentillas; in actuality a clone with 7/8" diameter yellow flowers on a dwarf bushy framework, see 'Farreri'.
- 'Goldfinger'—Compact, mounded, 3' by 4' shrub with large, bright yellow, 1 3/4" diameter flowers that occur into fall; dark green foliage; it has proven to be a superior clone in the Midwest.
- 'Goldstar' ('Gold Star')—This form keeps cropping up in my European travels and I believe it will become popular in the future; deep yellow-gold, 1 1/2 to 2" diameter flowers are borne in abundance particularly in cool climates; mildew resistant and trouble-free; 3' high, 2 to 2 1/2' across, from West Germany.
- 'Goldteppich'—Somewhat similar to 'Dart's Golddigger' with smaller flowers and larger, deeper green leaves; golden yellow, 1 1/4 to 1 1/2" diameter flowers are produced in great numbers.
- 'Grandiflora'—Flowers bright yellow, 1 3/8" diameter, with large dark green leaves; ultimate height about 6'; abundant flowers; 3' by 4' at Arnold.
- 'Hollandia Gold'—Large, dark yellow flowers; medium green leaves; medium texture; low, mounded form; suffers chlorosis and leaf scorch under water stress.
- 'Hopleys Little Joker'—Seedling of 'Red Ace'; very compact and low-growing; flowers are red but fade to white with a red margin, particularly in the heat.
- 'Hopleys Orange'—Rounded shrub, 2' by 2'; warm deep orange flowers, flowers on-and-off for several months, color less intense in heat; Bressingham Nursery introduction, original plant from same nursery that produced 'Red Ace'.
- 'Hurstbourne'—Bright yellow small flowers on a fine-textured, compact, globe form.
- 'Irving'—Golden yellow small flowers on a fine-textured, dense, 3' high shrub.
- 'Jackmanii' ('Jackman's Variety')—A larger form, 3 to 4' high; good dark green almost bluish green foliage color, and a profusion of bright yellow, 1 1/4 to 1 1/2" diameter flowers; has performed well in the Midwest; stops flowering before 'Goldfinger' and 'Coronation Triumph' at least in the Urbana, IL area; originated in the nursery of Messrs. Jackson, Woking, Surrey, England.
- 'Katherine Dykes'—A fine form with gracefully arching branches and seldom growing more than 2 to 3' high; the medium green foliage is glaucous-tinged and provides a framework for the lemon yellow, 1" or slightly wider flowers that are freely produced; 4 1/2' by 3 1/2' at Arnold, with age may become twiggy and unattractive; have read size estimates of greater than 6' high; arose in the garden of W.R. Dykes and named after his wife.

- 'Klondike' ('Klondyke')—A dwarf, compact shrub about 2' high is studded with 1 1/2" diameter, deep yellow flowers; foliage is bright green above, bluish green below; did not perform well at Arnold.
- 'Knap Hill' (also 'Knap Hill Buttercup')—Small, bright yellow flowers produced all season; medium green leaves; fine texture; dense low-mounded form; rated highly by Bachtell and Hasselkus; showed good tolerance to water stress but suffered slight dieback at -19°F.
- 'Kobold'—Low, compact; fresh green leaves; masses of small, yellow flowers from June into fall; 18" or greater.
- 'Lady Daresbury'—Large, bright yellow flowers, 1 1/2" diameter, sparsely produced after initial strong showing; blue-green leaves; medium height, to 3' and broad-spreading form; foliage chlorotic and bronzed under water stress.
- 'Limelight'—Free flowering, soft yellow flowers with bright yellow center; bright green foliage.
- 'Logan'—Dark yellow flowers; pale green leaves; fine-textured, low, mounded form; may suffer from water stress.
- 'Longacre'—Similar to 'Elizabeth' but lower and more spreading; flowers large, bright sulfur-yellow; shiny dark green leaves; 3' by 4'; heavy flowers at Arnold; self-sown seedling at Longacre Garden, Northern Ireland.
- 'Maanelys' ('Moonlight')—Soft yellow flowers about 1 1/4" diameter fading as they age but remaining darker at the center; foliage soft gray-green and silky above, whitish underneath; flowers from May to July–August; considered a low, mounded grower although may reach 4 to 5' by 8'; 4' by 4', 3/4" diameter yellow flowers at Arnold.
- 'Manchu' (var. *mandshurica*)—White flowers, 1" diameter, not prolific; a dense mounded shrub about 1 to 1 1/2' high; grayish green foliage; a rather wispy, shabby shrub at the Arnold.
- Mango Tango® ('UMan', PP 12,258)—Mango-orange and red bi-color flowers, color recedes in hot weather and like many orange/red types may fade to yellow, gold on outside of petals, orange-rose in center; witnessed at Minnesota Landscape Arboretum July 20, 2005 and flowers were yellow with slight-orange eye; 2' by 2'; University of Manitoba introduction.
- Marion Red Robin® ('Marrob', 'Hinerob', PP 9,321)—Listed as perhaps the best red by Forestfarm 2007; low-spreading habit with flowers slightly deeper red than 'Red Ace'.
- 'McKay's White'—Creamy white-flowering sport of 'Katherine Dykes' that occurred at McKay Nursery, WI; 2 to 3' high and 2 to 3' wide; no fruits; Zone 3.
- 'Medicine Wheel Mountain'—Compact, spreading habit; blue-green leaves; bright yellow flowers to 1 1/2" across.
- 'Mount Everest'—White, 1 to 1 1/2" diameter flowers in spring and summer on an upright branching shrub; 3' high, 5 leaflets; narrow, yellow-green.
- 'Mount Townsend'—Double to semi-double, yellow flowers, freely produced throughout summer (Washington); 18" high; discovered on Townsend Mountain in the Olympic Mountains in June 1994.
- 'Northman'—Rich yellow flowers, sage-green leaves and small habit; as I saw the plant, light yellow.
- 'Ochroleuca'—A seedling of 'Friedrichsenii' with bright green leaves and small cream-colored flowers; small erect shrub to 6'; may be confused in the trade for was described as spreading 4' by 6'.
- 'Orangeade'—Upright habit, bright green leaves, flowers orange-red; seedling of 'Red Ace', from Liss Forest Nursery.
- 'Pink Beauty' (PP 9,874)—Attractive pink flowers, single and semi-double, free-flowering; 2' by 2 1/2'; flower color holds reasonably well in heat; faded in July 2008 in Minnesota with barely any pink evident; bred by Louis Lentz, University of Manitoba.
- 'Pink Pearl'—Large, mid-pink flowers on a neat, mounded, spreading shrub, 16 to 20" high.
- 'Pink Whisper'—Flowers blushed with deep pink, may fade to soft yellow in heat; small to medium size, 2 to 3'; University of Manitoba introduction.
- 'Pixie Gold'—Smallish, 3/4", bright yellow flowers on 12 to 18" high and wide plant; small green leaves; Carroll Gardens introduction.
- 'Pretty Polly'—Small, salmon-pink flowers on a compact shrub, 14 to 20" high.
- 'Primrose Beauty'—A small (3'), free-flowering shrub with 1 3/8" diameter, primrose with deeper center flowers that pale with age; grayish green foliage; may grow 4 to 5' high and 6' wide; allied to 'Vilmoriniana' but is better and is considered one of the finest of all the garden hybrids; moderate flowering at Arnold.
- Princess™ ('Blink', PP 5,106)—Delicate pink flowers, white on the reverse, May into October but become smaller and may fade to white in the heat of summer; robust shrub to 30"; Bressingham Gardens introduction; beautiful as I have seen it in England, doubtfully as nice in the heat of the United States.
- 'Pyrenaica'—Perhaps a misnomer but plants with this name are dwarfish, 6 to 18" high, and have 1" diameter, bright yellow flowers.
- 'Red Ace' (PP 4,226)—I would like to relate that this is a superior red-flowering form but, unfortunately, that is not the case; it was introduced through Bressingham Gardens, England, and described as having 1" diameter, flaming vermillion petals, undercoated with yellow on an ultra-hardy, 2 1/2' by 2

1/2' framework; in the United States it is a weak grower and the flowers in heat or drought bleach out to yellow or pale orange-red; it is also quite susceptible to mite damage and leaf scorch; I grew it in my Illinois garden and was woefully disappointed; handsome in England where I have seen it in June, will fade there also in summer; arose as a chance seedling in 1973 in the nursery of Hopley's Plants, Much Hadham, England.

'Red Robin' (same as Marian Red Robin™)—Single, red flowers on a 24" by 28" framework; small attractive green leaves; Hines introduction.

'Red Sunset'—Orange flowers fading to yellow; listed by Leo Gentry, possibly a rename.

'Rhodocalyx'—Low-growing, flowers nodding, corolla white, pedicel and calyx crimson.

'Royal Flush' (PP 4,628)—A seedling from 'Red Ace' with rosy pink, yellow-centered flowers on a compact shrub, 12 to 18" high (twice as wide); leaves dark green; will lose its color and fade to soft pink or cream in hot weather.

'Ruth'—Small shrub, erect habit, with nodding, bell-shaped, cream flowers with red calyces.

'Sandra'—Ivory-white, 1 3/8" diameter flowers on a 3' high bushy shrub.

'Scarlet'—Red, from Leo Gentry, possibly a rename.

'Snowbird'—Cream-white, semi-double, 10 to 15 petals; dark green leaves; 2 to 3' mounded habit; University of Manitoba introduction.

'Snowflake'—Flowers white, single to semi-double, 1" diameter; not vigorous at Arnold.

'Sommerflor'—Listed in *Deutscher Gartenbau* 43:1282–1284 (1989) without description; several catalogs list this as bushy habit with large, bright yellow flowers and long flowering period; considered more heat tolerant.

'Stoeker's Variety'—White flowers, sparsely produced; glossy dark green leaves, almost leathery in appearance; medium texture, dense, globe form.

'Sundance'—Butter yellow, double flowers; light green foliage; 2 to 3'; University of Manitoba introduction.

'Sunset'—Pale yellow flowers tinged orange, retaining their unusual color but produced in small numbers; shiny medium green leaves; fine-texture, tall-mounded form; foliage may be chlorotic under water stress, has been noted that color may fade to yellow in hot weather.

'Sutter's Gold'—Bright yellow, silvery foliage, low-growing, 1 to 2' by 3'.

'Tangerine'—Medium yellow, pale copper orange or flushed with orange-red (copper-red) under ideal conditions; in full sun, flowers are yellow; 1 1/4" wide, gray-green leaves; 2' by 4', mounded, spreading shrub; raised by Slieve Donard Nurseries, Newcastle, Co. Down, Ireland.

'Tilford Cream'—White flowers on a compact plant, 12 to 18" high; leaves bright green.

'Veitchii'—White flowers with dull red stamens, 1" diameter; pale green leaves; to 5' high.

'Vilmoriniana'—Flowers pale yellow to creamy white with a yellow center, up to 1 1/2" diameter; silvery green leaves; stiffly erect shrub, 4 to 5' high; flowers borne sparsely over a long period.

'Walton Park'—Golden yellow, 1 1/2 to 1 3/4" diameter flowers; leaves deep green above, blue-green beneath; spreading shrub to 2' high.

'White Gold'—Medium yellow, large flowers; gray-green leaves; coarse-textured, low, mounded form; chlorosis and foliage bronzing may occur under water stress.

'William Purdom' ('Purdomii')—Canary yellow flowers, with a deeper center, 1 1/8" diameter; bright green leaves; fine-textured, large rounded, open, 4 to 6' high.

'Woodbridge Gold'—Flowers buttercup-yellow, 1 1/4" diameter, abundant over several months; leaves rich green and rather glossy; low-growing to about 2' by 3'.

'Yellow Bird'—Double yellow flowers, 8 to 10 petals, may produce single flowers; from Canada.

'Yellow Gem'—Bright yellow, 1 1/4" diameter flowers, ruffled attractive petals, May until frost; gray-green leaves; 16" high by 40" wide; University of British Columbia Botanical Garden introduction.

PROPAGATION: Seeds require no pretreatment. Softwood cuttings rooted 100% under mist in peat:perlite when treated with 1,000 ppm IBA; very easy to root from softwood cuttings but reduce the water as soon as they root; tissue culture has been successful, see *Plant, Cell, Tissue Organ Culture* 32:235–240 (1993).

ADDITIONAL NOTES: Wyman noted that one cultivar grown in the Arnold Arboretum in the same location for 60 years was 3' tall and had never required pruning or spraying. I have seen the Arnold and the Minnesota Landscape Arboreta's extensive collections of *Potentilla fruticosa* and wondered how anyone could separate them without labels. Many look similar in flower color, habit, and foliage characteristics. The logical approach would be to select the best 5 to 10 and use this as a guide. Continued breeding and selection are occurring so, no doubt, more clones will inundate an already confused group of plants. Their extreme hardiness and summer flowering sequence make them valuable landscape plants.

In June 1996, as I scurried through the National Botanical Garden of Ireland (Glasnevin) a *P. fruticosa* collection jumped in front of my camera and tape recorder. Madly I spat words into the machine with camera smoking and belching. After 20 minutes of this insaneness, I became totally confused by the similarity of habit, foliage, flower, et al., told myself it was time to quit and walked to the butterfly-bush collection, a much easier group to distinguish, particularly since they were only in leaf. There is a moral here. I will let the reader decide.

I agonized about adding more but here goes from my sabbatical notes and Hillier 2002 in abbreviated fashion:

- 'Bulleyana'—Gray leaves, bright yellow flowers.
- 'Cascade'—Apricot with pink center.
- 'Chelsea Star'—Bright green leaves; vivid yellow flowers.
- 'Chilo'—Leaflets edged cream, unstable; weak grower; yellow flowers.
- 'Dart's Cream'—Gray-green leaves, cream-yellow flowers.
- 'Eastleigh Cream'—Green leaves; cream, 1" diameter flowers.
- 'Farrer's White'—White flowers.
- 'Glenroy Pinkie'—Dwarf shrub; large pink flowers, my field notes say this is the best pink.
- 'Golden Spreader'—Bright yellow flowers.
- 'Grace Darling'—Gray-green leaves; peach-pink flowers.
- 'Groneland'—Bright green foliage; off-white flowers.
- 'Hersii'—Dark green leaves; white flowers, often semi-double.
- 'Janet'—Bright green leaves; large, pale-yellow flowers.
- 'Jolina'—Gray-green leaves to 1 1/2" across; large, golden-yellow flowers, wide-spreading, cascading habit.
- 'King Cup'—Medium green leaves; large, vivid yellow flowers.
- 'Kingdon Ward'—Gray to sage-green leaves; large, yellow flowers.
- 'London Town'—Pale yellow flowers.
- 'Milkmaid'—Cream-white flowers.
- 'Mustard Dwarf'—Green leaves; bright yellow flowers.
- 'New Dawn'—Pink, deeper in center, grading to white at ends of petals.
- 'Orange Star'—Yellow with orange margins to petals.
- 'Penny White'—Bright green leaves; white, single to semi-double flowers.
- 'Sandved'—Light green leaves; large white flowers.
- 'Silver Schilling'—Silver-gray leaves; 1 1/4" diameter, golden-yellow flowers.
- 'Sophie's Blush'—White flowers.
- 'Whirligig'—Soft green, silky pubescent leaves; bright yellow flowers, petals wavy.
- 'White Rain'—White flowers.

The RHS Plant Finder 2008–2009 listed the following taxa that were not included in my two lists. They are: 'Alice', 'Apple Blossom', 'Argentea Nana', Baby Bethan™, 'Bewerley Surprise', 'Clotted Cream', 'Frances Lady Daresbury', 'Golden Dwarf', 'Goscote', 'Haytor's Orange', 'Hopleys Pink', 'Lemon & Lime', 'Lovely Pink' ('Pink Beauty'), 'Macpenny's Cream', 'Maybe', 'Peaches and Cream', 'Peachy Proud', 'Summer Sorbet', 'Super Ace', 'Tom Conway', 'Valley Gold', 'Wessex Silver', 'Wickwar Beauty', 'Wickwar Trailer', 'Wychbold White', 'Yellow Carpet', and 'Yellow Giant'.

Shrubby Potentilla, *RHS Trials and Awards Bulletin* was published in June 2002. Retrievable at www.rhs.org.uk. Ninety-six taxa were trialed from 1996 to 2001/2002. I listed those not in the previous treatment and lists. Those that were rated the best include:

Large yellow flowers: 'Jackman's', 'Medicine Wheel Mountain', 'Summerflor' and 'King Cup'.

Small yellow flowers: 'Chelsea Star'.

Average yellow flowers: 'Yellow Bird'.

White flowers: 'Groveland', 'Penny White', 'Abbotswood'.

Cream or pale yellow flowers: 'Limelight', 'Primrose Beauty'.

Pink flowers: 'Pink Beauty' (Lovely Pink™).

Orange flowers: 'Hopleys Orange'.

Red flowers: Marian Red Robin™ ('Marrob').

Those in the RHS Trials but *not* in the rest of the discussions in the Manual include: 'Burren Gold', 'Glenroy Flattie', 'Glenroy Seashell', 'Gold Parade', 'Hazel', 'Honey', 'Hunter's Moon', 'Judith', 'Mallows Pink', 'Pastel Pink', 'Perryhill', 'Pink Glow', 'Springwood Cream', 'Subalbicans', 'Sungold', 'Teesdale Silver', 'Teesmaid', and 'White Beauty'.

NATIVE HABITAT: Northern Hemisphere.

Prinsepia sinensis (Oliv.) Oliv. ex Bean — Cherry Prinsepia

(prin-sē'pi-a sī-nen'sis)

FAMILY: Rosaceae

LEAVES: Alternate on current season's growth, produced in clusters on the year old shoots, simple, ovate-lanceolate to lanceolate, 2 to 3" long, about 1/2" wide, long acuminate, entire or sparingly serrulate, finely ciliate, otherwise glabrous, bright green; petiole—slender.

BUDS: Small, indistinctly scaly, concealed in brown hairs, buds may develop into spines.

STEM: Long and slender, round, spiny (1/4 to 1/2" long), light gray-brown; pith—chambered; on older stems the bark exfoliates to varying degrees.

SIZE: 6 to 10' in height and as wide; specimen at Arnold was 10' high and wide.

HARDINESS: Zone 4 to 7; Cappelletto reported as not cold hardy in Maine, however Minnesota Landscape and Morton Arboreta have grown for years.

HABIT: Haystack to rounded, dense, spiny shrub well-adapted for hedges and screens.

RATE: Medium.

TEXTURE: Medium in leaf, perhaps medium-coarse in winter.

BARK: On old stems brown and shredding off in long papery strips.

LEAF COLOR: Bright green in summer; fall color of little consequence, perhaps yellow-green; usually the first shrub to leaf out, have seen leaves in early to mid-March at the Arnold Arboretum; during 1991 sabbatical at Arnold leaves were one-third developed by March 25, also drops leaves early in fall.

FLOWERS: Perfect, small, light yellow, 5-petaled, 10-stamened, almost creamy yellow, borne in fascicles of 1 to 4 on previous year's wood in March–April, each flower about 3/5" diameter, on a 1/2" long pedicel, worthwhile but not overwhelming.

FRUIT: Red, cherry-like, 1/2" long, subglobose or ovoid drupe which ripens in July, August and September and is effectively digested by birds; color is actually more orange to purple than red; supposedly edible; contains large amounts of ascorbic acid, dry matter content is 2.5 to 4 times that of currants, cherries, and apples; less sugar than most cultivated fruit plants; stone ovoid, flattened.

CULTURE: Easily transplanted, of undemanding culture, requiring only fertile, well-drained soil and open, sunny location; probably best to renewal prune when plants become overgrown; withstands pruning quite favorably.

DISEASES AND INSECTS: One of its principal merits is resistance to pests.

LANDSCAPE VALUE: Not a very common shrub but one certainly worth considering for hedges, screens or barriers; quite serviceable shrub and requires minimal maintenance; the endearing trait of being the first shrub to thrust its green leaves upon the spring landscape makes it worthwhile considering; no one characteristic is particularly outstanding but the sum of all the parts equals a good, serviceable shrub that could be utilized effectively on difficult sites.

PROPAGATION: Apparently seed germination is somewhat variable and the reports in the literature do not emphasize the best treatment; seeds will germinate when sown directly but a 2 to 3 month cold treatment definitely improves germination. Cuttings collected in June rooted 65 to 75% when treated with 3,000 to 8,000 ppm IBA; 100% rooting was obtained with August cuttings and 8,000 ppm IBA, mist; a higher hormone concentration is advisable.

Prinsepia uniflora appears more difficult to germinate and root; seeds will germinate if sown directly but cold treatments have produced variable results. Cuttings are difficult but can be rooted in July and August with high hormone and patience; during sabbatical I tried to root this species but was unable to induce a single root.

NATIVE HABITAT: Manchuria. Cultivated 1896.

RELATED SPECIES:

***Prinsepia uniflora* Batal. — Hedge Prinsepia**
(prin-sē'pi-a ū-ni-flō'ra)

LEAVES: Alternate, simple, linear-oblong to narrow-oblong, 1 to 2" long, 1/2 to 3/4" wide, distinctly toothed, each serration terminated by a short bristle, lustrous dark green above, light green below, glabrous; petiole—1/4" long.

BUDS: Small, indistinctly scaly, long, slender, scale-like appendages tend to mat together.

STEM: Slender, pale-gray to straw-brown, slight ridges, glabrous, small orangish bumps (lenticels); spines 1/2" long, slender, sharp-pointed, borne singly above a node; pith—greenish white, finely chambered.

Prinsepia uniflora, Hedge Prinsepia, is a rather thorny, moderately dense aggregate of light gray branches growing 4 to 5' high with a similar spread. The Minnesota Landscape Arboretum has both species growing side-by-side and the growth habit and foliage characteristic differences become immediately evident. The leaves are very dark green, 1 to 2" long and not as densely borne as those of *P. sinensis*. The flowers are white, 3/5" wide, 5-petaled, 10-stamened, 1 to 3 together along with the leaves from nodes of the previous season's growth, on a 1/4" long glabrous pedicel. The fruits are globose, about 1/2" long, dark purplish red,

bloomy, maturing in late summer. The stone is ovoid, flattened. The fruits are quite handsome and hang down from the branches in a rather pretty fashion. Interestingly, of two plants in the Arnold Arboretum, one fruited heavily, the other bore no fruits. This species would also make a good hedge or barrier and on the basis of foliage color is superior to *P. sinensis*. Rare in cultivation. Native to northwestern China. Introduced 1911. Zone 3 to 5(6).

Prunus L. — Cherries, Peaches, Plums, Apricots, Almonds

FAMILY: Rosaceae

The genus *Prunus* comprises over 400 species and numerous hybrids. The distinctions between species and cultivars are often difficult. Herein, I have presented an encapsulated treatment of the more popular ornamental types. The cherries provide a freshness to our gardens that is seldom achieved with any other plant. The delicate flowers pass quickly but in their finest hours are the equal of any ornamental tree. Unfortunately, *Prunus* as a group is beset with insect and disease problems and perhaps should not be looked upon as long-term garden investments. Some, such as *Prunus subhirtella*, *P. sargentii*, *P. xyedoensis* and selected *P. serrulata* types, can be expected to live for 30 to 50 years while *P. persica*, *P. cerasifera* 'Atropurpurea', *P. xcostena*, and *P. glandulosa* may decline in 5 to 10 years.

Leaves are alternate, deciduous or evergreen, usually serrate with prominent, usually vestigial stipules. Flowers are white, pink to red, solitary, in clusters or racemes, 5-petaled, 5-lobed calyx, numerous stamens, solitary pistil, ovary superior. Fruit is a 1-seeded drupe of various shapes, often bloomy; stone often compressed.

I have monitored flowering cherry performance from Maine to the coast of Georgia and northern Florida. For the colder climates, I would opt for *P. sargentii* and *P. subhirtella*, in the mid to deep South, *P. xyedoensis*, *P. campanulata* and *P. 'Okame'*.

Had a great study opportunity to assess cherries in 1999 during sabbatical in England and noted 227 entries in my field notes on the species and cultivars. Some of the purpleleaf plums were flowering February 19, 1999, while *P. padus* 'Watumi' was flowering March 30, 1999. Quite a span of time to assess *Prunus* and I did so with gusto.

ADDITIONAL NOTES: Two excellent books include Collingwood Ingram. 1948. *Ornamental Cherries*. Country Life, LTD, London; and Geoffrey Chadbund. 1972. *Flowering Cherries*. Collins, London. The first individual is considered the greatest force in ornamental cherry breeding and introduction. His 'Okame', correctly *P. xincamp* 'Okame', was introduced in 1947 and 60 some odd years later is receiving rave reviews from American gardeners. See discussion under *P. campanulata*. A trip through Ingram's book opens one's eyes to the beauty and diversity of flowering cherries. A more recent reference is Kuitert and Peterse. 1999. *Japanese Flowering Cherries*. Timber Press.

Prunus americana Marsh. — American Red Plum, also known as Wild Plum, August Plum, Hog Plum
(prō'nus a-mer-i-kā'na)

LEAVES: Alternate, simple, obovate to oblong-ovate, 2 to 4" long, 1 1/4 to 1 3/4" wide, acuminate, broad cuneate, sharply and doubly serrate, dark green and glabrous, or slightly pubescent on midrib below; petiole—1/3 to 3/4" long, pubescent, without glands.

Prunus americana is a common shrub or small tree, often forming large colonies along roadsides, in waste areas and other uncultivated habitats throughout its native range. I have seen the typical colonies which almost remind of sumacs the way they spread. Also, single-stemmed, 15 to 25' trees are evident. Tri-national champions are 30' by 10' in Gadsden Co., FL, 18' by 50' in Fairfax, VA and 17' by 17' in Yavapai, AZ. Flowers are pure white, about 1" diameter, on a slender, 2/3 to 1" long, glabrous pedicel, 2 to 5 together in sessile umbels. Flowers open before the leaves in early to mid-March in Athens and depending on temperature are effective for 5 to 7 up to 14 days. A pronounced difference in flowering times is evident as one colony will be spent while another is in full splendor. Flowers have that sickly sweet typical plum species odor. Fruits are generally yellow to red, rounded, about 1" long with yellow flesh that ripens in June–July. The fruits are utilized for jellies and jams. Cultivars have been selected for superior fruit quality. Obviously requires no special cultural requirements. Tends to thrive with neglect. Found from Massachusetts to Manitoba, south to Georgia, New Mexico and Utah. Cultivated 1768. Zone 3 to 8.

RELATED SPECIES:

Prunus angustifolia Marsh., (prö'nus an-gus-ti-fō'li-a), Chickasaw Plum, is another suckering, colonizing shrub with comparable attributes. National champion is 86' by 48' in Clatsop State Forest, OR. Branches are covered with thorn-like side branches. The leaves are 1 to 2" long, one-third as wide, oval-lanceolate, strongly trough-shaped, acute, broad cuneate or rounded, fine glandular-serrate margined, lustrous dark green above. The white, fragrant, 1/2" diameter flowers occur 2 to 4 together before the leaves. Fruit is a 1/2" diameter, rounded, lustrous red (yellow) drupe. This species is quite common in the Southeast and forms large, suckering colonies much like *Rhus glabra*. Flowers are evident in early to mid-March (Athens) and remind that spring is close at hand. Doubtfully useful in a contrived, cultivated situation but has merit for highway plantings and wildlife areas. Maryland and southern Delaware to Florida, west to Arkansas and Texas. Introduced around 1874. Zone 5 to 9.

Prunus avium L. — Gean, Mazzard or Sweet Cherry

(prö'nus ā'vi-um)

LEAVES: Alternate, simple, oblong-ovate, 2 to 6" long, 1 1/2 to 2" wide, acuminate, unequally serrate, dark green and often slightly rugose above, more or less pubescent beneath, of soft texture; petiole—1 to 1 3/4" long with prominent often reddish glands near the blade.

Prunus avium is a large tree of conical

shape growing to 70' or more but usually under cultivation reaches 30 to 40' with a similar spread. National champion is 96' by 73' in West Chester, PA. The emerging foliage is bronze, becoming deep green in summer and turns yellow to bronze in fall. Flowers are white, 1 to 1 1/2" diameter, fragrant, mid to late April, in several flowered umbels. The fruit is a reddish black, rounded drupe about 1" in diameter. This is the species from which most of our popular sweet cherry clones are

derived. On a garden tour through Germany, the plant was everywhere in evidence on the slopes above the Rhine River. Also, at Mainau, the species was underplanted with tulips and daffodils, all flowering at the same time. Although not common as an ornamental in the Midwest and East, it is one of the longer-lived cherries. 'Plena' has double, white, 1 1/2" diameter flowers with as many as 30 petals and is superior to the species for flower effect. The Arnold Arboretum had a tree that was spectacular when in flower. An enterprising nurseryman could sell this form. There are many clones of importance for commercial fruit production. I noted 76 cultivars listed in RHS Plant Finder, 2007–2008. Europe, western Asia. Cultivated since ancient times. Zone 3 to 8. One of the hardiest cherries and might be used where the Oriental types are not hardy. Does reasonably well in Athens.

Prunus besseyi Bail. (*Prunus pumila* var. *besseyi* (Bail.) Gleason according to GRIN) — Western Sand Cherry, Sand Cherry

(prö'nus bes'sē-i)

LEAVES: Alternate, simple, oval, oval-lanceolate, sometimes obovate, 1 to 2 1/2" long, acute, cuneate, shallowly serrate on upper two-third's, glabrous, gray-green; petiole—1/4" long.

Prunus besseyi is a suckering, spreading, 4 to 6' high and wide shrub. The gray-green leaves are rather attractive and provide a different foliage color than most *Prunus* species. In late April–early May the shrub literally glows with pure white, 1/2" diameter flowers that give way to sweet, purplish black, 3/4" long fruits in July and August. I have only seen the plant in flower on one occasion and, indeed, it is attractive but cannot compete with the Oriental cherries. The species is found in the Great Plains and tolerates rather inhospitable, hot, dry conditions. It prefers a well-drained soil. Many cultivars have been selected for fruit quality with 'Black Beauty' (small, black, sweet) and 'Hansen's' (large,

purple-black, flavorful) the most notable. 'Gus Mehlquist' (var. *depressa*) is a prostrate form of sand cherry, slender mid-green foliage is bluish white on lower surface, leaves turn wine-red in fall; white flowers in spring are followed by dark red fruits; 2 to 2 1/2' by 5' in 5 years. Pawnee Buttes® grows 15 to 18" by 4 to 6' and is a groundcover form of *P. besseyi*; lustrous green leaves turn bright red and purple; white flowers and black fruits; a Colorado Plant Select® introduction. Manitoba to Wyoming, south to Kansas and Colorado. Introduced 1892. Zone 3 to 6.

Prunus campanulata Maxim. — Bell-flowered, Taiwan, or Formosan Cherry
(prö'nus kam-pan-ü-lā'ta)

LEAVES: Alternate, simple, ovate, oval or slightly obovate, 2 1/2 to 4 1/2" long, 1 to 1 3/4" (2 1/2") wide, slender-pointed, broadly wedge-shaped to slightly heart-shaped at the base, margins regularly set with fine forward-pointing or slightly incurved teeth, lustrous dark green, 6 to 8 vein pairs, glabrous; petiole—1/2 to 3/4" long; stipules feathery, much divided.

Prunus campanulata is a small, graceful tree ranging from 20 to 30' in height. The young leaves emerge rich green and become dark green at maturity and develop bronzy red fall color. Before the leaves emerge, the deep rose, 3/4" diameter flowers appear 2 to 6 together on 1/2 to 3/4" long pedicels that arise from a 1 to 1 1/2" long peduncle. The calyx tube is also deep rose and offers color after the petals have abscised. The red fruits are about 1/2" long and about 3/8" wide. In my mind, the flowers may be the most handsome of all ornamental cherries. I have seen flowers as early as late January in Athens, GA, but they usually open in February. I have been in Savannah on February 22 and the leaves were almost fully mature. In my garden, the tree was in full leaf by mid-March. Many years past, I received a seedling from the late Mr. Jack Jones, Savannah, GA after admiring flowering trees in his garden. The tree grew 15' high and wide with three strong, polished, reddish brown trunks. It ranks as one of my all time favorites simply because it is the first to flower and offers spectacular rose-carmine flowers. Because of the early flowering date, buds and/or flowers may be injured if they are too far open. Has flowered in early February along with *Hamamelis mollis*. This is a most effective combination, the bright yellow of the witchhazel and the rose-carmine of the cherry. Seeds will germinate in the spring following fall planting, I suspect a slight cold requirement is required. Early June cuttings, 5,000 ppm KIBA, peat:perlite, mist, rooted 80%. It is probably best cultivated in the lower part of Zone 7 to 9. Temperatures of 0°F did not injure flower buds. The biological years extracted their revenge on the Dirr garden specimen and the last vestiges were removed in 1996. Observations indicated that late spring freezes were more damaging than typical Zone 7 winter low temperatures. For best performance, Zone 8 to 9 is recommended. Native to Taiwan, southern China, Ryukyu Islands of Japan. Cultivated 1899.

The late Dr. Don Egolf, U.S. National Arboretum, utilized *P. campanulata* in several innovative crosses including hybrids with *P. incisa* and *P. subhirtella* 'Autumnalis Rosea'. I have evaluated these hybrids since 1992 and am impressed by flower color, abundance, plant vigor and heat tolerance in the South. The double rose form may open as early as the first week in February, as late as the third week, with flowers effective for 3 to 4 weeks as the calyces are reddish and showy. Have rooted this as yet unnamed hybrid numerous times. The original trees grew 25 to 30' high. One of the most beautiful heat tolerant cherries, much more potent than *P. subhirtella* 'Autumnalis Rosea'.

'Okame' with carmine-pink petals (March–April), a rose-red calyx, and reddish flower stalks is hardier and very striking. Flowers are fully open by mid to late February in Athens. Leaves are fully developed by mid to late March. It has performed well in the Arnold Arboretum, Middle Atlantic States and on the Georgia campus. It is the result of a cross between *P. incisa* and *P. campanulata* raised by Collingwood Ingram. It definitely should be more widely planted for it also offers a good bronze to orange-red fall color. 'Okame' received the prestigious Styer Award from the Pennsylvania Horticultural Society and is now common in commerce. Will mature between 20 and 30' with a similar spread. 'Okame' has proven an outstanding cherry for Zone 6 to 8. The habit is almost broad-columnar in youth gradually feathering to a more rounded outline. A small rooted cutting in our garden was 18' high in only 6 years. The shiny, reddish brown bark is ringed with grayish lenticels; quite handsome in the winter landscape.

'Collingwood Ingram' has an upright habit, 18' by 6'; deep rose-red buds open rose-pink, flat-corolla, deeper than 'Okame', opening March 15, 1999 at Hillier; beautiful cherry, seedling of 'Kursar' raised at Kalmthout in 1979 and named after the man who enriched our gardens with many beautiful cherries. 'Dream Catcher' was released by the U.S. National Arboretum in 1999. It is an open-pollinated seedling of 'Okame' that grew 25' by 20' in 12 years. Single, bright pink flowers open one week after 'Okame'. Full flower, Milliken Arboretum, March 8, 2006, pink-white and not as described in the press release. Tree was not particularly striking. On March 21, 2009 at Milliken, flowers were largely past and leaves were more bronzy than 'First Lady'. Habit moderate vase-shaped, i.e. "V". Dark green leaves turn orange red in fall; foliage is relatively resistant to insects. Again, foliage tatty and ragged in October–November at Milliken. Would anyone purchase the tree based on what I documented? No! Hardy in Zone 6 to 9. 'First Lady' has single, deep rose-pink flowers like *P. campanulata* and a fastigate-upright, oval habit, grows 28' by 18'; dark green leaves, yellow-orange to red fall color; U.S. National Arboretum introduction. Flowered February 16, 2006 at Raulston Arboretum and was truly outstanding. At Milliken, March 21, 2009, flowers were deep pink like 'Okame' and leaves were about 1/3 mature size, more green and further along than 'Dream Catcher'. Might also mention that at Milliken, 'Dream Catcher' was more open, spreading in habit than 'First Lady.' 'Kursar' is another Ingram hybrid, smaller in stature than 'Okame', upright vase-shape with rich deep pink flowers in early March (Hillier); one Hillier tree was 28' by 20', another 24' high and upright spreading; first noticed in flower February 22, 1999; *P. campanulata* × *P. nipponica* var. *kurilensis*.

Prunus caroliniana (Mill.) Ait. — Carolina Cherrylaurel

(prō'nus ka-ro-lin-i-ā'na)

LEAVES: Alternate, simple, evergreen, oblong to oblong-lanceolate, 2 to 3" (4") long, 1" (1 1/2") wide, sharp apex, cuneate, margin entire or with several spiny teeth toward apex, leaves on seedlings or young plants more toothed than those from mature plants, glabrous, lustrous dark green; petiole—slender with 2 small glands, red in sun, green in shade.

STEM: Reddish on young stems, brownish on older, with a distinct maraschino-cherry odor when bruised or broken, perhaps the most potent odor of the cherries and all have this odor or a modification to some degree.

SIZE: 20 to 30' (40') high, 15 to 25' spread; have seen large trees 40' high with a 30 to 40' spread; national champion is 48' by 46' in Harris County, TX.

HARDINESS: Zone 7 to 10.

HABIT: Large evergreen shrub, or more often small tree of pyramidal-oval to rounded and irregular outline; usually dense and full but not always uniform in outline; often pruned into a hedge or screen.

RATE: Fast.

TEXTURE: Medium.

BARK: Dark gray to almost black.

LEAF COLOR: Lustrous dark green through the seasons, although will discolor in winter sun and wind; new growth rich yellow-green or bronze.

FLOWERS: Perfect, 5-petaled, white, sickeningly fragrant, 1/4" across, borne in 1 1/2 to 3" long, 3/4 to 1" wide racemes out of the leaf axils in March–April (usually late March to early April in Athens); flowers are not overwhelming but welcome by virtue of the early date.

FRUIT: Green maturing to lustrous dark black, 3/8 to 1/2" diameter, top-shaped drupe, ripen in October, not particularly conspicuous as they are masked by the foliage; persist into winter and until flowering during the spring, abundant; birds deposit the seeds all over the landscape and consequently stray seedlings appear everywhere.

CULTURE: Easily transplanted, adaptable, prefers moist, well-drained soils and here grows like a weed; pH adaptable; withstands heavy pruning; full sun to partial shade.

DISEASES AND INSECTS: Leaf spot, some damage from chewing insects, have not noticed any serious problems, subject to ice, snow, wind damage, have seen what appears to be an *Entomosporium* leaf spot.

LANDSCAPE VALUE: Utilized widely for screens and hedges in the South; has been used to soften harsh vertical lines of large buildings; should not be planted too close to a residence, tends to overgrow its boundaries; used at Williamsburg by the early colonists; one of the few plants that can seed into a privet hedge and win; the weedy nature is something to be considered before making wholesale use of the plant; have seen it "everywhere" in the Coastal Plain of Georgia and South Carolina especially along fence rows and in waste areas; actually makes a pleasant small multi-stemmed tree or large shrub, just be cognizant that stray seedlings will appear; have seen seedlings so dense under a tree that they formed a groundcover.

CULTIVARS:

Bright 'N Tight™ ('Compacta')—Compact, tightly branched, pyramidal form with smaller leaves than the species, leaves rarely have serrations; superior to the species for most situations; have seen 15- to 20-year-old plants at Disneyworld about 20' tall; sold under the name 'Compacta' in much of the nursery trade to avoid the hassle of the trademarked name.

Cherry Ruffles™—Compact selection with a wavy leaf margin, introduced by Flowerwood Nursery.

PROPAGATION: Seeds can be fall sown and will germinate the following spring; seeds with pulp removed, sown in November, germinated immediately; if a cold requirement exists it is indeed brief, probably 30 days would be sufficient. Softwood and greenwood cuttings will root and I suspect November–January or later hardwoods; cuttings collected on August 23 (Athens), 2,000 ppm KIBA, 2 perlite:1 peat, mist, rooted only 50%.

ADDITIONAL NOTES: Distinct cherry odor is evident when stems are bruised; leaves carry a high concentration of hydrocyanic acid which makes the plant unpalatable and dangerous to livestock.

NATIVE HABITAT: Coastal Virginia to northern Florida and west to Louisiana.

Prunus cerasifera Ehrh. — Cherry Plum or Myrobalan Plum

(prō'nus ser-a-sif'ēr-a)

FAMILY: Rosaceae

LEAVES: Alternate, simple, ovate, elliptic or obovate, 1 1/2 to 2 1/2" long, 1 to 1 1/4" wide, apex pointed, broadly wedge-shaped or rounded, finely obtuse-serrate, glabrous above, bright green above, green beneath, usually less than 6 vein pairs, pubescent on midrib and major veins beneath, petiole—about 1/2" long; if glands are present they usually occur at base of the blade near the point of petiole attachment.

SIZE: 15 to 30' by 15 to 25'.

HARDINESS: Zone (4)5 to 8.

HABIT: Small, shrubby tree, twiggly and rounded, with ascending, spreading branches.

RATE: Fast.

TEXTURE: Medium in all seasons.

LEAF COLOR: Light green in summer, no significant fall color.

FLOWERS: Perfect, solitary, white, 3/4 to 1" across, sickeningly fragrant, sometime in April before the leaves, open around early to mid-April (mid-March, Athens); usually borne solitary.

FRUIT: Reddish, slightly bloomy edible drupe, approximately 1" across, June, July or August.

CULTURE: This discussion applies to the *Prunus* species. Transplant bare root, balled-and-burlapped or container-grown materials in spring; any average soil is acceptable but should be well-drained; pH adaptable; full sun; prune after flowering although potential fruits will be cut off; keep trees vigorous as there are numerous serious insects and diseases associated with *Prunus*; they are not particularly pollution tolerant and in most cases are short-lived (approximately 20 years) although certain species are much more durable than others; if the gardener would think in decades instead of lifetimes the pleasurable experience of growing some of the *Prunus* would be just that.

DISEASES AND INSECTS: Almost hopeless to list them all but some of the worst include aphids, borers, scale, tent caterpillars, canker, leaf spots.

LANDSCAPE VALUE: The species has minimal value and is only known in cultivation, but the following cultivars are extensively (over-used) used for specimens, groupings, and in foundation plantings; there is something about a purple-leaved beast that excites people to spend money.

CULTIVARS: For true collectors, the reference *Purpleleaf Plums*, Timber Press (1992) is must reading. I have the book . . . best to wonder why . . . but does harbor many things you want to know about Purpleleaf Plums.

'Alfred'—An unknown to me but described as white-flowered, with 1 1/4" wide fruit; upright-spreading habit, 20' by 15'.

'Atropurpurea' ('Pissardii')—Upright, dense branching form with reddish purple foliage and 3/4" diameter, light pink flowers, which open before the leaves (usually); often called Pissard Plum; introduced into France around 1880 from Persia (now Iran) through the efforts of Mr. Pissard, gardener to the Shah; for best foliage color the purple-leaved forms should be sited in full sun; in this particular form the new unfolding leaves are ruby red, later claret and finally dark reddish purple; the fruits are also purplish; it is shakily hardy in Zone 4 and a hard winter will produce some tip or branch dieback; found as a branch sport before 1880 and a number of selections have arisen from this selection either through hybridization or sports.

'Clark Hill Redleaf'—Tree form, leaves deep red, pink flowers in early March, fruits, 3/4 to 1 1/4" diameter, red with yellow flesh, originated near Savannah River, collected in 1973/74, possibly of seedling origin, see *Fruit Varieties Journal* 43:58–59 (1989).

Crimson Pointe™ ('Cripoizam')—Columnar-fastigiate-vase-shaped habit, 20' by 5 to 6'; new growth orange-bronze maturing to rich merlot-purple; pink buds open to white flowers; deep purple fruits; discovered by Dan Nelson, Hans Nelson & Sons Nursery; Lake County Nursery introduction; listed as Zone 2 which I doubt, more likely 5; so-so at Milliken Arboretum, most leaves abscised on October 5, 2008; leaves bronze-green, certainly not red-purple, significant Japanese beetle damage.

'Festeri'—Round-headed tree growing to 30', pink flowers in spring, leaves red when young, turn purple with age, fruit 1" long, edible.

'Hessei' ('Hessii')—Has narrow, irregular, reddish brown leaves with a yellowish margin and golden rim; interestingly flowers are white, opening in late February (February 27, 1999) at Hillier; tree was 25' high and 25' wide although described as a shrubby form in the literature.

'Hollywood' (also called 'Trailblazer')—I have never been able to determine the exact nature of this selection and the literature is conflicting; flowers are light pink to white before the leaves; leaves dark green above, red purple below; distinct upright habit and may grow 30' by 20'; red fruits 2 to 2 1/2" wide, hybrid between *P. c.* 'Atropurpurea' and the 'Duarte' Japanese plum; have also seen the parentage listed as *P. cerasifera* 'Nigra' × 'Shiro' Japanese plum.

'Krauter Vesuvius' ('Vesuvius')—Similar to 'Thundercloud' but more upright oval-rounded; light pink flowers before leaves; new leaves purple-bronze, maturing dark purple; 30' by 20', supposedly quite heat tolerant; flowers were white-pink, 1/2 to 3/4" diameter, on March 12 at the Milliken Arboretum, Spartanburg, SC (buds swelling February 28, 2003); I compared this cultivar to 'Thundercloud' and simply could not find any tell-tale morphological differences between the two.

'Lindsayae'—Habit is upright, flowers pink (February 18 to 27, 1999) before leaves; green leaves; good-looking tree; supposedly difficult to propagate; introduced from Iran.

'Mt. St. Helens'—A branch sport of 'Newport' with a straighter, stronger trunk; faster growing than 'Newport', leafs out earlier in spring; new leaves bronze-purple, has longer and wider leaves than the parent, richer purple color that holds later in summer; flowers good pink, late February–early March, Milliken Arboretum; round-headed tree, 20' by 20'; a J. Frank Schmidt introduction.

'Newport'—Probably the hardiest of the purple-leaf types; a cross between *P. cerasifera* 'Atropurpurea' and the 'Omaha' Plum; introduced in 1923 by the University of Minnesota Horticultural Research Center; new growth light bronze-purple, finally changing to dark purple; pale pink to almost white flowers (full flower, mid-February, Athens) and dull purple, 1" diameter fruits; a round-headed tree 15'(20') high; best in Zone 5 but can be grown in 4; Cappiello reported occasional tip dieback at Orono, ME, while 'Thundercloud' was killed outright; appears to be the common form in the southern states, and has flowered before 'Atropurpurea' or *P. x**cistena* even opened a single bud.

'Nigra'—Foliage very dark purple, color is retained through summer; flowers single, pink, 5/8" diameter; this may be the same as 'Vesuvius'; also 'Woodii' is similar.

'Pendula'—Observed at Hillier, white flowers, 30% full March 5, 1999; semi-pendant branches; green leaves; not particularly attractive.

'Purple Pony'—Appears to hold up better in heat; good foliage color like *P. x**cistena* but a tree-form habit; single, pink flowers; 10 to 12' high.

'Purpusii'—Have seen several descriptions for the plant: the first called it a delicate scrambled mixture of plum-red and creamy white; the other bronze with yellow and pink variegation along the midrib and white flowers.

'Thundercloud'—Single, pink flowers before the leaves, fragrant; retains its deep purple foliage through growing season; unfortunately, not hardy at Madison, WI and I have observed injury at Urbana, IL, 20' by 20'; introduced in 1987, at Milliken Arboretum flowers opened later than 'Krauter Vesuvius'; in Michigan study, 30 to 70% defoliation each year by gypsy moth.

'Trailblazer'—Red-purple leaves initially, maturing bronze-green; white flowers on March 9, 1999 at Hillier, not as heavily plum-scented, plant 10' by 10'; edible red fruits; considered a hybrid, discovered as a seedling in Oregon.

PROPAGATION: *Prunus* seeds have an embryo dormancy and require a period of after-ripening; generally 2 to 3 months at 40°F will suffice; seeds can also be cleaned and sown outdoors in fall with germination occurring the following spring. Cuttings show variable response depending on the species and cultivar; there is some indication that NAA may be more effective on *Prunus* than IBA but it is best to start with IBA and then experiment with NAA; in my own work, I have found the purple-leaf types easy to root with 1,000 to 3,000 ppm quick dip; this also applies to the evergreen *P. laurocerasus* and cultivars; *P.* 'Hally Jolivette' has proven easy; I know nurserymen who are producing 'Kwanzan', *P. x**yedoensis* and others from softwood cuttings; from a practical standpoint it is better to establish many *Prunus* on their own roots to avoid possible graft incompatibilities; at Shadow Nursery, Winchester, TN, I have seen two-year-old rooted 'Kwanzan' cherries in the field that were 6 to 8' high; tremendous movement to own-root cherry and plum; slightly firmer cuttings seem to root in higher percentages than extremely soft May–June material, rooted cuttings will grow if lightly fertilized, overwintering does not appear to be a problem.

NATIVE HABITAT: Western Asia, Caucasus. Introduced before or about the 16th century.

RELATED SPECIES:

Prunus* ×*blireana André, (prō'nus blēr-ē-ā'na), Blireana Plum, is a hybrid between *P. cerasifera* 'Atropurpurea' and a double form of *P. mume*. It is a rounded, dense branching tree with reddish purple foliage that fades to green and double, 10- to 15-petaled, edges undulating, pleasantly fragrant, pink, 1 to 1 1/4" diameter flowers in March–April, before the leaves. Fruits are purplish red and lost in the foliage so as not to be effective. Grows 20' by 20'. 'Moseri' has deeper purple leaves and smaller flowers, strong-growing, observed at Hillier Arboretum and did not appear much different than *P. ×blireana*. Put into commerce by Lemoine in 1906. Zone 5 to 7. Several high-octane plants of 'Moseri' at Duke Gardens that flowered profusely in early March (March 9, 2007), the branches clothed with double pink flowers, habit vase-shaped, spreading, uniform.

Prunus* ×*cistena (Hansen) Koehne, (prō'nus sis-tē'na), Purpleleaf Sand Cherry, is a cross between *P. pumila* and *P. cerasifera* 'Atropurpurea' and grows 7 to 10' tall usually with a slightly smaller spread. The foliage is intensely reddish purple and stays effective throughout summer. The flowers are single, pinkish, fragrant, borne after the leaves have developed in April–early May. Fruits are blackish purple. Easily propagated from softwood cuttings. One of the hardiest purple leaf plants. 'Minnesota Red' ('Minnesota Purpleleaf') has deeper reddish purple leaf coloration that persists into fall. Big Cis® ('Schmidtciis') is a branch sport of *P. ×cistena* that grows twice as fast producing a rounded, dense, 14' by 12', small tree; the reddish purple leaves are larger, the trunk heavier; flowers are pink like the parent; a J. Frank Schmidt introduction. All *P. ×cistena* types in Zone 7 and 8 struggle and are almost defoliated by late summer. They are much better adapted in the northern climes. Introduced by Dr. N.E. Hansen of South Dakota State University in 1910. Zone 3 to 7.

Prunus glandulosa Thunb. — Dwarf Flowering Almond

(prō'nus glan-dū-lō'sa)

LEAVES: Alternate, simple, ovate-oblong or oblong to oblong-lanceolate, 1 to 3 1/2" long, 3/4 to 1" wide, acute, rarely acuminate, broad-cuneate at base, crenate-serrulate, medium green, glabrous beneath or slightly hairy on midrib; petiole—1/4" long; stipules linear with gland-tipped teeth.

Prunus glandulosa is the bargain basement shrub of many discount stores.

It grows 4 to 5' tall and 3 to 4' wide and is a spreading, weakly multi-stemmed, straggly shrub. The summer foliage is light green. Flowers are pink or white, single or double, late April to early May, one or two together. Fruits are dark pink-red, 1/2" across and rarely produced. Chief value is in the flower. Basically a very poor plant, single season quality, appearing distraught and alone in summer, fall and winter. Cannot get over the hump with this plant when I consider all the wonderful viburnums that could be utilized. Stands out in flower and then disappears, perhaps this is not all bad. Roots easily from cuttings. 'Alba' has pure white, single flowers. 'Alba Plena' ('Alboplana') has double, white flowers and 'Rosea Plena' ('Sinensis') double, 1 to 1 1/4" diameter, pink flowers. I saw a single, pink-white selection called 'Lawrence' in full flower in late March at Callaway Gardens, the double form nearby was still in tight bud. Every time I visit Coach Dooley's Athens garden he delights in showing me the "beautiful" Dwarf Flowering Almond. I just roll my eyes! Central and northern China, Japan. Introduced 1835. Zone 4 to 8. Some tip dieback at Orono, ME.

***Prunus* 'Hally Jolivette'**

'Hally Jolivette' is the result of a cross of *P. subhirtella* × *P. xyedoensis* backcrossed to *P. subhirtella* by Dr. Karl Sax of the Arnold Arboretum. It is a rounded, dense branching, shrubby tree growing 15' and of relatively fine texture. The flowers are pink in bud, opening pinkish white, double, 1 1/4" diameter and effective over a 10 to 20 day period in late April to early May as the flowers do not all open at once. I rooted a cutting and planted it in my Illinois garden. The plant grew 3' or more a year and in the

second year flowered. Still one of my favorite cherries and I have seen 20' tall trees. Have heard about disease problems that may afflict the tree, but have not observed outright kill. The parentage indicates respectable adaptability. Easy to root from May, June, July cuttings; tissue culture was successful, see *HortScience* 18:182–185 (1983). Introduced 1940. Zone 5 to 7.

Prunus incisa Thunb. — Fuji Cherry

(prō'nus in-sī'sa)

LEAVES: Alternate, simple, ovate to obovate, 1 to 2 1/4" long, 2/3 to 1 1/4" wide, acuminate, incisely double serrate, medium to dark green, pubescent above and below on veins; petiole—about 1/3" long, pubescent with 2 purple glands near blade; leaves reddish when first emerging.

Prunus incisa is a large shrub or low-branched tree, generally 15 to 20'(30') high. The small delicate leaves turn yellow, bronze, and red in autumn. The flowers are white to pale pink, campanulate, 3/4 to 1" across, and open before the leaves in March. Typically mid to late March at the Raulston Arboretum. Petals are notched or jagged at their ends. The flowers are extremely delicate and are subtended by the vinous red calyx. The fruits are 1/4 to 1/3" long, ovoid, purple-black drupes. This species does not appear long-lived in the midwestern, eastern, and southeastern United States. Served as a parent of 'Okame'. Cultivars include: 'February Pink' with early, pale pink flowers; 'Kojo-no-mai', a smallish, almost shrub form, 4' by 3', with twisted branches and pale pink (white) flowers, was in every garden center that I visited during the 1999 sabbatical in England; now, 2009, showing up in U.S. commerce; 'Moerheimii' a spreading, weeping form with long, trailing branches, covered with pale pink flowers; 'Omoioyama' with profuse, double, pale pink flowers; and 'Praecox' with pink-budded, open white, early flowers. Grows in great profusion on the slopes of Mt. Fuji. Wilson noted that no cherry is more hardy, more floriferous or more lovely. Dr. John Creech (*NMPro* 17(9): 47–48, 50 (2001)) describes two cultivars grown from seed collected by the U.S. National Arboretum in 1982. 'Fair Elaine' has pale pink petals, dark pink sepals, reddish bark and is quite vigorous. 'Snow Cloud' is smaller-statured with white pendent flowers that become pinkish with age. The latter was in full flower March 22, 2003 in the Dirr garden. In 1999, I witnessed the following in flower: 'February Pink', 20' by 20', March 8; 'Fujimae', single, white, red calyx, 12', upright habit; 'Kojo-no-mai', described above; 'Odoriko', pink to white flowers, tree habit; 'Oshidori', double, pale pink, upright habit; 'Pendula', beautiful weeping form; and 'Praecox', early white, February 18, at RHS Wisley, Japan. Cultivated 1910. Zone 5 to 6(7).

Prunus jacquemontii Hook.f. — Afghan Cherry

(prō'nus jak-mon'tē-ī)

Limited exposure caused me to question inclusion. I received the plant under three different names but all appeared similar in the Georgia trials. Plants are now 3 to 4' high, about as wide, not the neatest habit, with small, rich green leaves. Flowers, deep rose in bud open rich pink on naked stems in late March (Athens) and are quite potent as there is little competition. Fruits are red but I have yet to observe them on Georgia plants. Any well-drained soil in full sun is adequate. Foliage looks disheveled in late summer. Received as 'Hirome', 'War Eagle' and *P. japonica*. Zone 6 to 8. Northwest Himalaya, Tibet, Afghanistan. Introduced 1879.

Prunus laurocerasus L. — Common Cherrylaurel, English Laurel

(prō'nus lâr-ō-sēr-ā'sus)

LEAVES: Alternate, simple, evergreen, 2 to 6"(10") long, about 1/3 to 1/2 as wide, usually oblong or obovate-oblong, acuminate, cuneate to rounded at base, obscurely serrate to nearly entire, glabrous, lustrous medium to dark green above, 2 to 4 glands present on base of blade near point of attachment to petiole (seldom), or on underside of leaf at varying distances from point of petiole-blade on either side of midvein (commonly); petiole—1/2" long.

BUDS: Solitary or collaterally multiple, sessile, subglobose or mostly ovoid with usually 6 exposed scales.

STEM: Slender or moderate, green, subterete or somewhat angled from the nodes, typical cherry odor when bruised; pith roundish or angled, pale or brown, continuous; leaf scars raised on a cushion flanked by the stipule vestiges or scars, half-round or half-elliptical, small; 3 bundle traces, usually minute.

SIZE: Species can grow 10 to 18' high and under ideal conditions might become 25 to 30' wide but is smaller under cultivation and principally represented by the cultivars; national champion is 33' by 52' in Seattle, WA; gigantic plants in England with trunks like beech trees, 30' high plants are common.

HARDINESS: Zone 6 to 8.

HABIT: Large, wide-spreading, evergreen shrub of solid, dense constitution, extremely bold element because of large lustrous dark green leaves; have observed as low-branched tree.

RATE: Medium, 10' in 5 to 6 years under good conditions.

TEXTURE: Medium in all seasons.

LEAF COLOR: Lustrous medium to dark green in summer; loses some of its sheen in cold climates.

FLOWERS: Perfect, white, each flower 1/4 to 1/3" across, 20 stamens, April–May, (early April, Athens) born in 2 to 5" long, 3/4" wide racemes from the leaf axils, sickeningly fragrant.

FRUIT: Conical-rounded drupe, purple to black, 1/3 to 1/2" long, summer, often lost among the leaves.

CULTURE: Transplant balled-and-burlapped or from a container; lately I have seen most being sold in containers; although a great number of large plants are offered balled-and-burlapped from the West Coast; performs best in moist, well-drained soil supplemented with organic matter; pH adaptable; full sun or shade, salt spray tolerant; avoid excessive fertilization; withstands pruning very well; best in partial to heavy shade in well-drained soil.

DISEASES AND INSECTS: Not as susceptible to the problems which beset the tree *Prunus* but I have seen considerable foliage damage accomplished by insects, a shothole-type disease produces circular holes in the leaf that look like a shotgun was aimed at the plant; has become a significant problem in production nurseries where overhead watering is practiced, plants suffer from poorly drained soils and I have observed too many declining or dead plants because of this; several years past I was called to a large corporate site in Atlanta to assess the reason for many dying plants; 'Otto Luyken', a selection of the species, was used in great numbers and bright brown plants were everywhere in evidence, plants were installed in January, I came in late May; I pulled one plant out of the ground and heard this slush, slosh, glush, glosch sound; obviously no drainage; moral: if the soil is not drained plant Baldcypress; root rot is also a problem that relates to inadequate drainage.

LANDSCAPE VALUE: Relatively handsome hedge plant; popular in the South; is not too successfully used north of Philadelphia; makes a good plant in the shade especially some of the cultivars, often used in groupings or masses; in fact, 'Otto Luyken' may be massed 50 to 100 in one location.

CULTIVARS: Numerous cultivars (over 40) have been described from Europe. The late J.C. Raulston, NCSU, assembled a fine collection of cultivars and produced an excellent cultivar checklist; see *Proc. Southern Nurseryman's Res. Conf.* 39:364–368 (1994). I have attempted to incorporate J.C.'s observations with mine to provide a wide-angle view of the various taxa.

'Batumi Rubies'—Upright form with long, lanceolate, arching, leathery, lustrous dark green leaves on strong, upright stems; vigorous growing; estimate 10 to 15'; large, vigorous plant in Raulston Arboretum with fruits maturing red to black; probably excessively coarse for commerce; fruits listed as red; leaves infected by *Entomosporium*; collected by Dr. Todd Lesseigne in Soviet Georgia.

'Camelliafolia'—Lustrous dark green leaves, twisted, curled, disfigured; certainly other-worldly foliage; 30' high plant at Hillier; have only observed small plants in the U.S.

'Castlewellan'—See 'Marbled White'.

'Caucasica Nana'—Small, compact shrub with full, erect branching habit and thickly textured, rich green leaves.

'Cherry Brandy'—As observed at Hillier, a low growing form, probably no more than 18 to 24" high; bronze young growth.

Etna™ ('Anbri')—Rather handsome, compact, broad-upright form with pretty lustrous dark green leaves that clothe the branches; caught my attention in the Winter Garden at Hillier, in 1999 plants were 2 1/2' by 3' and more attractive than 'Otto Luyken'; I have yet to see this cultivar in the U.S.

'Forest Green'—Black-green foliage form, broader, darker green leaves than 'Schipkaensis'; grows 4 to 6' high; chance seedling from Bear Garden Nurseries, Silver Spring, MD; supposedly quite cold hardy.

'Magnoliifolia' ('Latifolia', 'Macrophylla', 'Magnifolia')—Large form with 10 to 12" long, 3 to 4 1/2" wide leaves; it may be trained into a tree; Dick Ammons, Florence, KY, mentioned that this was a shiny-leaved, hardy form; a massive 20 to 25' high, 1 1/2 to 2 times as wide specimen has prospered at Kew Gardens, leaves remind of *Magnolia grandiflora* and are extremely lustrous, almost black-green; for textural effect this is a superb plant.

- 'Majestic Jade'—Upright, broad-columnar from in youth with lustrous dark green leaves, becoming more rounded with age and remaining dense and full; original plant 10 to 12' by 8 to 10'; more resistant to leaf spot than 'Otto Luyken', its parent; I grew >100 seedlings from 'Otto Luyken' with four selected, the lone survivor, 'Majestic Jade', named by my wife, Bonnie; I experience numerous 'West Coast Skips' in the Zone 7 to 8 market when 'Majestic Jade' is an extraordinarily better choice.
- 'Marbled White'—Lustrous green leaves initially bronze-variegated, maturing to cream and green, not uniform, large splotches and streaks of cream on some leaves, not much on others, an unstable chimera; 'Castlewella' is probably the same plant.
- 'Mischeana'—Compact, dense, flat-topped, wide-spreading, lustrous dark green leaves; collected in Balkans, apparently by Spath, Berlin in 1898, Hillier considers this one of the most beautiful forms; as I witnessed it a companion to 'Otto Luyken', only smaller.
- 'Mount Vernon'—Small, compact, 3' high and wide form with large species type leaves; I got so excited the first time I saw the plant at Carlson Nursery in Oregon; Mr. Carlson gave me 5 cuttings and all rooted, 13 years later in my garden the plants were 2 to 3' tall, grows very slowly and might be a good plant in a rock garden; Raulston suggests 3 to 5' high and 5 to 8' wide; introduced by Wells Nursery, Mount Vernon, WA.
- 'Nana'—Listed at 4 to 6' high with foliage similar to species, from Monrovia.
- 'Otto Luyken'—Quite a fine form of compact habit, leaves dark green, 4" long, about 1" wide; very free-flowering; have seen it in heavy shade where it flowered profusely; grows 3 to 4' high and may spread 6 to 8'; introduced about 1968 by Hesse Nurseries, Weiner, Hanover, Germany; have seen 6' high by 10' wide plants in England, 10' tall plant at Hillier in 1999; easily separated from 'Schipkaensis' and 'Zabeliana' because of the way the leaves are disposed at an upward, 60 to 45° angle to the stem, in the other two cultivars the leaves are more or less perpendicular to the stem or slightly drooping, respectively; usually the leaves of this form are not toothed toward the apex.
- 'Parkway'—Probably 'Magnoliifolia', named by Woodlanders, Aiken, SC.
- 'Schipkaensis'—A dark green, narrow-leaved form found in 1889 near the Shipka Pass at 4,000' in Bulgaria; it is probably the hardiest of the cherrylaurels and I have observed plants with good foliage after a winter of -6°F; the leaves are 2 to 4 1/2" long and 3/4 to 1 1/2" wide; it is more refined than the species and forms a rather wide-spreading plant at maturity probably seldom growing more than 4 to 5'(10') high; leaves may be entire or show only a few teeth toward the apex; Zone 5 to 8; at least 3 other 'Schipkaensis' forms are known and differ in growth habit, size and leaf characteristics.
- 'Serbica'—A large, upright, vase-shaped shrub or small tree with thickish, obovate leaves; 10' high plant at Hillier; originally discovered in the former Yugoslavia.
- 'Variegata'—Leaves resembling those of the species and conspicuously mottled and variegated with creamy white, fairly robust and attractive, Zone 6 or 7, tends to revert; several white blotched and dotted forms are known; same as 'Castlewella'; catch-all category for variegated types? witnessed in Taff's Garden at Hillier.
- 'West Coast Schipkaensis'—Amazing how plants become mixed and this and 'Schipkaensis' are arriving in the Southeast, apparently on the same trucks, the West Coast version is much more upright, larger and rapid-growing with the large leaves spreading outward from the stems; I checked the leaf morphology and the West Coast form will be larger, firmer, serrated for much of the leaf margin, the typical 'Schipkaensis' is toothed toward the apex; be careful because if mixed in landscape plantings, the results will be *odd*, and clients will question you on the outcome; 'West Coast Schipkaensis' is more common in the Southeast, largely produced by West Coast nurseries; much coarser than 'Schipkaensis'; there is a German clone listed as 'Schipkaensis Macrophylla' with leaves up to 8 to 9" that may prove one and the same.

'Zabeliana'—Leaves dark green, narrow, entire, willow-like and, quite similar to 'Schipkaensis'; very free-flowering; may grow to 3' and spread 12'; plants 5' high and 25' wide were noted; makes a good ground cover in dense shade; Zone 6 and does quite well in the South; put into commerce by Späth in 1898, along with 'Schipkaensis', the hardiest form, interestingly, laboratory hardiness tests indicated this was the most cold hardy cultivar, followed by 'Schipkaensis' and 'Otto Luyken'; see *J. Environ. Hort.* 8:71–73 (1990).

PROPAGATION: Seed requires a 2 to 3 month cold treatment, and radicles often emerge in the stratification medium. Cuttings taken in late summer rooted 90% in sand:peat in 7 weeks without treatment; have rooted this successfully many times; cuttings of the clone mentioned under additional notes were taken in early June and early July, 3,000 and 5,000 ppm IBA quick dip, respectively, peat:perlite, mist, with 100% rooting 4 weeks later. Tissue culture, *Acta Horticulturae* 300:177–180 (1992), was successful with 'Otto Luyken'.

ADDITIONAL NOTES: Other cultivars are known and appear in European literature. For reference: 'Gajo', Genolina™ ('Mariblon'), 'Green Marble', Low 'n Green™ ('Interlo'), 'Mano', 'Milky', 'Novita', 'Otinii', 'Prostrata', Renault Ace™ ('Renlau'), 'Reynvaanii', 'Rotundifolia', 'Taff's Golden Gleam', and 'Van Nes' are listed in RHS Plant Finder 2008–2009. Since *Prunus* species are under post-entry quarantine procedures, it is difficult to introduce new(er) selections. Need to follow USDA-APHIS regulations since the introduction of a single pest could devastate *Prunus* much like Emerald Ash Borer has accomplished with *Fraxinus*.

NATIVE HABITAT: Southeastern Europe and Asia Minor. Introduced 1576.

RELATED SPECIES:

***Prunus lusitanica* L.**, (prō'nus lū-si-tan'ī-ka), Portuguese Cherrylaurel, is a large, bushy, evergreen shrub or small tree 10 to 20' high but occasionally larger. European literature reported tree-like stature to 60'. All my early sightings correlate with shrub stature. The 1999 sabbatical in England opened my eyes to 30 and 40' high specimens. The ovate or oval, 2 1/2 to 5" long, 1 1/4 to 2" wide, glabrous, toothed, glossy dark green leaves are handsome throughout the year. The white, 1/3 to 1/2" diameter, plum-fragrant flowers are produced in 6 to 10" long, 1 to 1 1/4" wide racemes in May–June from the ends of the previous season's growth and from the axils of their leaves. In England, flowers were noted at Hillier in early May to early June. The 1/3" long, cone- to top-shaped fruits are shiny red maturing dark purple-black. This is a rather handsome plant and surprisingly has survived on the campus of Reinhart College, Walesca, GA where winter temperatures ranged from 0 to –10°F. One reference reported that *P. lusitanica* was hardier than *P. laurocerasus*. I believe the species has potential for southern gardens. Plants at the Atlanta Botanical Garden, University's Botanical Garden, JC Raulston Arboretum, and UNC-Charlotte Botanical Garden have performed better than *P. laurocerasus*. Foliage is not affected by "shot hole." Performance in sun and shade is outstanding. Adaptable to high pH, limestone soils as well as acid and is remarkably heat and drought tolerant based on Southeastern performance. Could be useful to breed resistance into *P. laurocerasus*. European forms of the species are different than what I see in the Southeast. Habit on the European type is larger, looser and leaves are more lustrous and elongated. What is common in the Southeast could be a cultivar for 'Angustifolia' with 3" long, lanceolate leaves; 'Myrtifolia' with 2 to 2 1/2" long, ovate leaves, and neat rounded habit, have read that 'Angustifolia' is same as 'Myrtifolia', witnessed 'Myrtifolia' at Batsford Arboretum, April 24, 1999, and indeed the leaves are smaller; and 'Ormistonensis' with leathery dark green leaves and compact habit are described. 'Variegata' is quite common in European gardens, the leaves irregularly margined cream, but not overwhelmingly so. At Longstock Nursery, an infested 'Otto Luyken' was next to *P. lusitanica*, which did show some spotting. Plants I have observed under "normal" landscape conditions in the places mentioned showed no disease symptoms. Spain, Portugal. Introduced 1648. Zone 7 to 9.

Prunus maackii Rupr. — Amur Chokecherry, Manchurian Cherry

(prō'nus mak'ē-ī)

LEAVES: Alternate, simple, elliptic to oblong-ovate, 2 to 4" long, acuminate, rounded, finely serrate, medium green, gland dotted below, and slightly hairy on veins; petiole—1/2" long.

Prunus maackii is an interesting, rounded, to almost mop-headed, dense branching tree that grows 35 to 45' high. I have seen young trees that were pyramidal but with age the outline becomes more rounded. Although seldom credited with good flower characteristics, the white flowers occur in 2 to 3" long, 20- to 30-flowered

racemes in great profusion around early to mid-May. Numerous small, 1/4" diameter, red maturing to black, ovoid-globose fruits ripen in August. The bark is beautiful and I have seen many combinations and permutations. My first exposure to this tree occurred at the Royal Botanical Garden, Hamilton, Ontario, and on that tree the bark was a rich cinnamon brown and actually exfoliated in shaggy masses. Other trees I have seen showed minimal exfoliation. The color varies from brownish yellow to reddish brown to the cinnamon brown mentioned above. There were several magnificent trees near the old shrub collection at the Arnold and these make believers out of any gardener. Beautiful grouping at the entrance to Tower Hill Botanic Garden near Worcester, MA in 2006. The tree requires a well-drained soil and is best suited to cold climates. Seeds germinated best with 30 days warm, followed by 60 days cold stratification. It can be rooted from June–July softwoods. 'Amber Beauty' is uniform in habit with slightly ascending branches and amber colored bark. Saw at Rosemoor on March 14, 1999; not that different from everyday seedlings I experience in the U.S. Korea, Manchuria. Introduced 1878. Zone 3 to 6.

Prunus mandshurica (Maxim.) Koehne — Manchurian Apricot
(prō'nus man-shūr'i-ka)

LEAVES: Alternate, simple, broad-elliptic to ovate, 2 to 5" long, half as wide, acuminate, rounded or broad-cuneate, sharply and doubly serrate, with narrow elongated teeth, deep green above, green beneath and glabrous except axillary tufts of hairs; petiole—1" long, puberulous.

Prunus mandshurica is a small (15 to 20'), spreading, round-headed tree that is most noteworthy for the single, pinkish, 1 1/4" diameter flowers that occur in April or early May before the leaves. It is rather handsome in flower and where peach and other *Prunus* cannot be relied upon for flower, this species might be considered. Fruits are globose, 1" diameter, and yellow. Old plants have an interesting gray, ridged-and-furrowed bark. Tree can grow larger than listed above, but I have not seen anything larger than 25' high under cultivation. 'Manchu', 'Moongold', and 'Sungold' are hardy cultivars. Manchuria, Korea. Cultivated 1900. Zone 3 or 4 and south.

Prunus maritima Marsh. — Beach Plum
(prō'nus ma-rit'i-ma)

LEAVES: Alternate, simple, ovate or elliptic, 1 1/2 to 3" long, 3/4 to 1 1/4" wide, acute, cuneate, evenly and sharply serrate, dull green and glabrous above, paler and soft pubescent below; petiole—1/4" long, pubescent, often glandular.

Prunus maritima is a rounded, dense, suckering shrub growing to 6' high and more. The flowers are white, single, 1/2" across, May, 2 to 3 together. Fruits are dull purple, sometimes yellow to crimson, 1/2 to 1" diameter, bloomy, ripening in August and relished for jams and jellies. Observed numerous plants on Cape Cod, no two alike, with fruit colors all over the spectrum.

A number of cultivars ('Eastham', 'Hancock', 'Squibnocket') have been

selected for superior fruit qualities. Variety *flava* G.S. Torrey is a yellow-fruited form apparently found wild on the Cape. This species abounds on Cape Cod, MA and is one of the Cape Codder's cherished plants. A good salt tolerant species which grows in sandy, rocky soils along the coast from New Brunswick to Maine and Virginia. Steve Spongberg, former Director, Polly Hill Arboretum, Martha's Vineyard, showed me an immense, low-branched specimen on the Island. A favorite comment of mine "... I did not know it grew that large." At times, my colleagues and I are so focused on commercial numbers that we forget these niche native plants fit the setting. Introduced 1818. Zone 3 to 6.

Prunus mume Sieb. & Zucc. — Japanese Apricot
(prō'nus mū'may)

LEAVES: Alternate, simple, broad-ovate to ovate, 2 to 4" long, long acuminate, broad cuneate, finely and sharply serrate, rich green above, pubescent on veins below; petiole—1/2 to 3/4" long, glandular.

STEM: Polished, shining green, glabrous.

Prunus mume was a favorite of the late Dr. J.C. Raulston and his continuous exhortations enthused me to the point that the plant was included in the Manual. Prior to J.C.'s proselytizing, I had only seen the plant once at the Missouri Botanic Garden in summer and all I remember was the polished green stems. However,

in February of 1989, my graduate student and I discovered a double pink form in flower in the University's Botanical Garden. I was converted. Since my non-believer days, the plant has shown up on the garden radar screen with increasing frequency. In fact, a handsome double pink form that I rooted from an unnamed clone at Milliken & Co., was 12' high and greets the early January—early February period with bulbous buds and fragrant, 1" diameter flowers. Interestingly, this form has better summer foliage than many cultivars and does not develop the droopy, almost desiccated foliar appearance in the summer. The species' habit is rounded with long, supple, green stems that produce 1 to 1 1/4" diameter, fragrant, white, pink to pale rose flowers, singly or in pairs on naked stems in January—March. Flowers opened in late December 2001 in Dirr Garden, still with flower February 3, 2002. Chief attraction is the winter flowering character and the plant becomes obscure later. Have read several interesting thoughts on pruning the plant to obtain best flower. Cut back after flowering to produce long branches which will form next year's flower buds. From here, cut half the branches back every year so a guaranteed crop of flowers will be present while the other half (not cut back) will produce heavy bud set the following summer. My experience . . . let it be . . . pretty obvious that even the longer, supple shoots develop flower buds, grading from more at the base to fewer toward the stem ends. Flowers (self-fertile) are also produced on the short spur growths along the inner stems and branches. Fruits are largely inedible, yellowish, globose, 1 to 1 1/4" diameter drupes. A reference noted that fruits are utilized fresh, canned or pickled in salt; the latter termed the Japanese pickled plum, Umeboshi. A well-drained, reasonably fertile, acid soil in full sun suits it best. Raulston mentioned that the Japanese have over 250 named cultivars in white, pink, rose, red, in single and double forms, on plants up to 20' high. Habit may be normal, fastigiate, corkscrew or pendulous. Interestingly, was difficult to locate in commerce in the United States but now more common. W.B. Clarke of California selected a number of forms.

CULTIVARS:

- 'Alba'—Single, white flowers, strong-growing form.
- 'Alba Plena'—Double, white flowers, to 20', early-flowering.
- 'Alphandii'—Semi-double, pink flowers.
- 'Andoh's White'—Pale pink, semi-double flowers.
- 'Benishidare'—Single, ruby crimson, cup-shaped, 3/8" diameter, very fragrant flowers.
- 'Beni-chidori'—Double, very fragrant, intense pink, fading later flowers, buds dark pink, late March—early April.
- 'Bonita'—Double, pink, 1" diameter flowers, semi-upright grower with rounded head, 25 to 30' high.
- 'Dawn'—Large, ruffled, double, pink flowers, one of the later flowering cultivars.
- 'Fragrant Snow'—White flowers
- 'Josephine'—Single, white flowers; from Tom Krasinsky, Chapel Hill, NC.
- 'Kanko Bai'—Profuse fuchsia-red flowers and orange-red fruit.
- 'Kobai'—Red, semi-double flowers.
- 'Matsurabara Red' ('Matsubara Red', 'Mitsubara Red')—Double, dark red flowers, actually more rose-red; upright tree to 20'; flowers January—February in mild winter climates, February—March in colder areas, early February at Raulston.
- 'Omoi-no-mama' ('Omoi-no-wac')—Semi-double, cup-shaped, white flowers, late March—early April.
- 'Peggy Clarke'—Double, deep rose flowers with extremely long stamens and red calyx; relatively common in commerce; observed in flower December 27, 2006 at Atlanta Botanical Garden; February 2–3, 2008 in Athens.
- 'Pendula'—Single or semi-double, pale pink flowers on a pendulous plant.
- 'Rose Bud'—Large, semi-double, soft pink flowers.
- 'Rosemary Clarke'—Large, double, fragrant, white flowers with red calyces, early to flower.
- 'Snow Cone'—Deeper pink flowers.
- 'Trumpet'—Early, pale pink, single flowers.
- 'Viridicalyx'—Double, white flowers with a green calyx, upright tree to 20'.
- 'W.B. Clarke'—Double, pink flowers on a weeping plant; quite respectable performance in Athens, typically in early February.

'White Christmas'—Very early, white, single flowers.

'Winter Mist'—Pale pink flowers.

Easily rooted from softwood cuttings in June, 3,000 ppm KIBA, mist. Cultivars are often grafted on peach ('Nemaguard') rootstocks. Have witnessed pronounced borer infestations on grafted plants. Seed requires a brief cold moist stratification. See Dirr, *Nursery Manager* 7(4):40–42 (1991), for an expanded discussion of the species. For the most part, not a long-lived species. I have planted some and watched them perish over time, even the Milliken tree mentioned previously. The wonderful flower abundance, fragrance and timing cannot be duplicated. So love them, and when they leave, plant more. Camellia Forest Nursery, Chapel Hill, NC, offers a great selection of *P. mume*. Japan, China. Introduced 1844. Zone 6 to 9, 10 in California.

Prunus nigra Ait. — Canada Plum, Canadian Plum

(prō'nus nī 'gra)

LEAVES: Alternate, simple, elliptic to obovate, 2 to 4" (5") long, half as wide, acuminate, broad-cuneate to subcordate, coarsely and doubly obtuse-serrate, dark green and glabrous above, pubescent or nearly glabrous beneath; petiole—1/2 to 1" long with two glands near point of attachment to blade.

Prunus nigra is a small, 20 to 30' high, upright branched, narrow-headed tree. White, 1 1/4" diameter flowers occur 3 to 4 together in the leaf axils on 1/2" long, reddish pedicels before the leaves in April–May. The fruit is a 1 to 1 1/4" long, oval, yellowish red to red drupe. 'Princess Kay' is a double, white-flowered form that was found by Catherine Nylund in the wild in Itasca County, MN; the plant was introduced by the Minnesota Landscape Arboretum. It flowers heavily as a young plant and produces red fruit in August. The prominent lenticels, in combination with the black bark, add winter interest. Plant at Milliken Arboretum, Spartanburg, SC, was going backward from the day it was planted. Dead in 2008. Northeast and upper Midwest into Canada. Introduced 1773. Zone 2 to 5(6).

Prunus padus L. — European Birdcherry, Common Birdcherry

(prō'nus pā'dus)

LEAVES: Alternate, simple, obovate to elliptic, 2 1/2 to 5" long, 1 1/2 to 2" wide, apex abruptly taper-pointed, base wedge-shaped, rounded or slightly cordate, teeth fine, very sharp, dull dark green above, grayish and hairless beneath or with axillary tufts; petiole—1/2 to 3/4" long, glabrous, with 2 or more glands.

Prunus padus is a medium-sized (30 to 40'), rounded, low-branched tree with ascending branches. The foliage is a dull dark green in summer and may become yellow to bronze in fall. The flowers are white, fragrant, 1/3 to 1/2" across, mid-April to early May; borne in drooping, loose, 3 to 6" long racemes after the leaves. The fruit is black, 1/4 to 1/3" diameter drupe, July to August. This is one of the first trees to leaf out and the new, lustrous light green leaves are a welcome sight after a difficult winter. Black knot disease has been serious in Minnesota and would be a limiting factor in the use of the species. A pretty tree that flowers after the leaves have matured, somewhat diminishing the overall effectiveness.

CULTIVARS:

'Albertii'—Pyramidal to rounded, 30' by 25' tree, upright habit, supposedly good for street tree use; flowers profuse on long racemes; Zone 3.

'Berg'—Tight globe-headed form to 25' high; new growth green quickly turning to dark red all summer; white flowers in 5 to 8" long racemes; Zone 2; selected by Clayton Berg, Helena, MT; 'Berg Redleaf' is synonymous.

'Colorata'—Offers bronze-colored new leaves that turn dark green above, purplish below, stems are dark purple, flowers light pink.

var. *commutata* Dipp.—Individual flowers 1/2" diameter in 6" long racemes, flowers 3 weeks before normal birdcherries; leaves emerge early, my notes say leaves with flowers close, March 2, 1999; 15 to 20' high, 20' wide; Zone 3 to 6.

Merlot® ('Drietreë')—Uniform upright habit; deep burgundy foliage color throughout the growing season; strong grower; more consistent branching than Summer Glow®.

'Plena'—Flowers large and double, remaining effective longer than any other form.

'Red Ball'—Brown-red leaves; young buds red, flowers white, sport of 'Colorata'.

'Spaethii'—Racemes somewhat pendulous, flowers 3/4" across.

Summer Glow® ('DTR 117')—New leaves green, maturing to excellent red-purple leaf color through summer, turn purple-red in fall; white flowers in 4" long, pendent racemes; 1/4" diameter, red fruits; strong semi-spreading growth habit has not exhibited suckering that is common to Schubert or Canada Red Chokecherry; well-adapted to urban sites; oval to rounded habit, approximately 25' high; Zone 3 to 7, a Wandell introduction.

'Watereri'—Racemes 8" long, quite effective in flower; have seen in June at Niagara Falls and was taken by the long and rather beautiful flowers; flowering March 30, 1999 at Hillier.

Reference to a fastigate clone (no name given) that was reproduced in tissue culture; see *J. Hort. Science* 68:975–981 (1993).

ADDITIONAL NOTES: European literature describes at least 15 cultivars varying in foliage and flower colors. Certainly not common in American commerce and most plants I experienced were in the midwestern states.

NATIVE HABITAT: Europe, northern Asia, to Korea and Japan. Zone 3 to 6. Long cultivated.

Prunus pensylvanica L. f. — Pin or Wild Red Cherry

(prō'nus pen-sil-vā'ni-ka)

LEAVES: Alternate, simple, ovate, 3 to 4 1/2" long, 3/4 to 1 1/4" wide, long-pointed, cuneate to rounded, sharply serrate, teeth incurved and gland-tipped, lustrous dark green, glabrous; petiole—1/2" long, with 1 or 2 glands.

STEM: Slender, shining, glabrous, reddish, aromatic when bruised.

Prunus pensylvanica is a small, slender, often shrubby tree with branches spreading at a broad angle forming a round-topped, oblong head. Size varies from 25 to 40' in height by 18 to 25' in spread. Co-national champions are 75' by 50' in Kalamazoo, MI and 75' by 42' in Great Smoky Mountains National Park, TN. This is a very rapid grower and can quickly develop in abandoned areas. The leaves are a lustrous deep green in summer changing to yellow and red in fall. The flowers are white, 1/2" across, May–June, borne in 2- to 5-flowered umbels or short racemes. Flowers with leaves just emerging on May 28, 2005 in Bucksport, Maine. Fruit is a light red, 1/4" diameter, globose, sour drupe which ripens in July through August. Very adaptable species as it forms a pioneer association on cut-over or burned-over forest lands; intolerant of shade and soon yields to other species. A useful "nurse" type tree much in the mold of Gray Birch in this respect. 'Jumping Pond' is a form with drooping branches but it suffers from a leaf spot disease. 'Stockton' is a double-flowered, compact, round-headed form; the leaves turn red in fall. Native from Labrador west to British Columbia, south to North Carolina and Colorado. Introduced 1773. Zone 2 to 5(6).

Prunus persica (L.) Batsch — Common Peach

(prō'nus pēr'si-ka)

LEAVES: Alternate, simple, elliptic-lanceolate or oblong-lanceolate, broadest about or slightly above the middle, 3 to 6" long, 3/4 to 1 1/2" wide, long-acuminate, cuneate, serrate or serrulate, glabrous, lustrous dark green; petiole—1/2" long, glandular.

STEM: Offers a valid identification characteristic for the upper portion is often reddish while the lower part is greenish, has a somewhat grainy appearance, glabrous.

Prunus persica as most people know, yields luscious, succulent, tasty fruit in summer. Yet the production of peaches is a highly specialized and technical art demanding considerable time, investment and luck. Peaches are notoriously susceptible to insect and disease pests. The Common Peach grows from 15 to 25' tall and usually develops a spread equal to or greater than its height. The habit is best described as one of ascending limbs and a low, broad, globular crown. The flowers are pink, 1 to 1 1/2" across, solitary or

paired, and develop in April (mid to late March, Athens) before the leaves. Early varieties in flower February 19, 2001, later March 22, 2003 at the University's Horticulture Farm. Actually, a mature peach orchard in flower is a magnificent experience. Flowers are often injured in cold winters or by late frosts. The fruit is a large, 3" diameter, almost globular, yellow and/or reddish, pubescent drupe which matures in June–July into August. Peaches present many problems culturally and the homeowner should not be discouraged if they fail. The best approach is to avoid peaches altogether. There are many single, semi-double or double-flowered forms of the common peach that are beautiful in flower but almost impossible to keep in good condition. The colors range from white through pink to deep red to variegated. I watched a double pink peach flower spectacularly for several years but consistent munching by the borers resulted in the death of the tree. The temptation to buy these forms based on flower alone is overwhelming, but one's enthusiasm should be tempered with the knowledge that the peach is prone to insects and disease. Ideally provide well-drained, acid, moist soil and full sun. There are numerous cultivars of both the fruiting and double-flowered forms and it is wise to check with the local nurseries for the best types for your area. The genetics of peach reproduction are unique for I know of double-flowering and weeping types that reproduce true-to-type from seed. In fact, in one Athens garden, white, pink, red, mottled, and double-flowered trees were all produced from seed. Over 40 ornamental cultivars are known, probably more. A few forms that I have observed and/or are offered through the nursery industry include:

'Alba Plena' ('Alboplana')—Rather handsome double, white form, flowers 2 to 2 1/2" diameter and are effective 2 to 3 times as long as single forms, occasional fruits are set, comes partially true-to-type from seed; a fine form on the Georgia campus was 20' by 20'; appears more resistant to insect and disease problems.

Corinthian™ Series—Upright, columnar-oval forms with green or red-purple foliage; white, pink and double flowers; bred by Dr. Dennis Werner, North Carolina State University; they include: 'Corinthian Rose' (PP 11,564; dark purple foliage and large, double, dark pink flowers), 'Corinthian Mauve' (PP 11,576; large double mauve-colored flowers), 'Pillar', 'Corinthian Pink' (PP 11,902; medium purple foliage and large, double, light pink flowers), and 'Corinthian White' (PP 11,493; large double white flowers).

Dwarf Forms ('Bonanza')—Many genetic dwarfs of varying flower colors, often bear fruits, kind of cute; 'Bonanza' is common.

'Early Double Pink', 'Early Double Red', 'Early Double White'—All offer the respective colors and multiple petals early in the season.

'Helen Borchers'—Clear pink, 2 1/2" wide flowers, late; have also seen this listed as semi-double with rose flowers.

'Peppermint Stick'—I remember trying to sell this form 35 years past at a garden center in Columbus, OH; flowers confused, being red- and white-striped, white or red often all on the same branch, double.

'Royal Red Leaf' ('Foliis Rubris')—Reddish purple young leaves deepening to maroon, flowers deep pink, fruit red-purple with a white flesh, edible; has been used as a rootstock to separate the scion growth more easily, if all red obviously the graft or bud did not take.

'Weeping Double Pink', 'Weeping Double Red', 'Weeping Double White'—Have seen a few of these types and generally they lack vigor or a strong constitution, perhaps in containers or as an accent but with limited long term value.

ADDITIONAL NOTES: The peach is native to China and has been cultivated since ancient times. Remarkable number of escaped peach seedlings along I-85 in NC, SC, and GA as well as I-40 in NC; I have assessed thousands at 65mph and see only pink in various shades; since breeders have produced dwarf, fastigiate, double, weeping and numerous improved fruit-bearing selections, it is odd that the highway variation is nil. Should peach be considered an invasive species? Zone 5 to 9.

Prunus sargentii Rehd. — Sargent Cherry

(prō'nus sār-jen'tē-i)

LEAVES: Alternate, simple, elliptic-obovate to oblong-obovate, 3 to 5" long, about one-half as wide, long acuminate, rounded or sometimes subcordate at base, sharply serrate with acuminate teeth, purplish or bronzy when unfolding, dark green above, glabrous and glaucescent beneath; petiole—1/2 to 1" long with 2 to 4 glands near the blade.

BUDS: Imbricate, conical-ovoid, reddish brown, sharply pointed, clustered at apex, often two buds at the nodes, one perhaps floral, the other vegetative.

STEM: Moderate, glabrous, reddish brown, marked with prominent lenticels, large gray-brown areas on stem.

BARK: Genuinely attractive, rich polished reddish to chestnut brown and marked with extended horizontal lenticels.

Prunus sargentii is one of the most useful cherries

available. It grows 40 to 50' in height with a spread approximately equal to height. Under cultivation, 20 to 30' high and wide would be more logical. The foliage is an excellent shiny dark green in summer and changes to bronze or red in the fall. The new leaves are reddish tinged as they emerge. The bark is rich, polished reddish to chestnut brown. The flowers are single pink, 1 1/4 to 1 1/2" across, borne on naked stems, late April to early May, buds just swelling March 21, 2009 at Milliken Arboretum, Spartanburg, SC, in full flower April 26, 1992 at Arnold Arboretum; borne in 2- to 6-flowered sessile umbels on 1" long pedicels. Full flower in Athens, mid to late March. Fruit is a 1/3" long, ovoid, purple-black drupe which ripens in June and July. Both the species and 'Columnaris' (a narrow, columnar clone) have proved excellent in evaluations at the Shade Tree Evaluation Plots at Wooster, OH. I watched this most beautiful tree throughout the seasons at the Arnold Arboretum and decided it was the handsomest of the larger tree types for the northern states. The rich pink flowers open ahead of the leaves producing a frothy mass in the early spring landscape. Tremendous tree to work into a large border and perhaps underplant with bulbs and complimentary shrubs. Fall color as mentioned is superb for a cherry and often carries a mixture of yellow-bronze-red. Perhaps the best of the larger cherries for general landscape use. 'Columnaris' forms an upright columnar to narrow vase-shape, although most trees I have seen were more vase-shaped than true columnar. Will probably grow 25 to 35' by 10 to 15'. Flowers and foliage are similar to the species. 'Rancho' is narrower than 'Columnaris', 20 to 30' by 8 to 10', with large deeper pink flowers than the species, and was introduced by Ed Scanlon. Recent literature tends to equate the two cultivars. I have observed that 'Columnaris' flowers latter than the species. Other selections with *P. sargentii* as one parent include:

'Accolade'—Semi-double, 12 to 15 petals, deep rose-pink in bud, opening blush pink, 1 1/2" across, on 3/4 to 1" long pedicels; dark green deeply serrated leaves; habit is open, spreading, 20 to 25'; *P. sargentii* × *P. subhirtella*; magnificent in flower, and the specimens that most incite passionate memories reside at Montecute House, Yeovil, England and Swarthmore College.

'Hillieri'—Single, blush pink, 1 1/4" diameter flowers are borne on slender long hairy pedicels; leaves bronzy when emerging, later dark green, double toothed, hairy on veins below, developing good bronze-red fall color; broad-rounded tree, 25 to 30' high and wide; probably *P. sargentii* × *P. xyedoensis*.

Pink Flair® (JFS-KW58)—Upright narrow-vase shaped, 25' by 15'; dark green leaves; orange-red fall color; single, clean pink flowers that are brighter pink and larger than typical of the species, one to two weeks later than species; at Milliken Arboretum maintained healthy foliage into late summer when 'First Lady' and 'Dream Catcher' were anything but; introduced by J. Frank Schmidt & Son Co.

'Shosar'—Interesting hybrid from Collingwood Ingram, (*P. incisa* × *P. campanulata*) × *P. sargentii*, flowers several weeks ahead of *P. sargentii*; narrow-crowned tree, 18' by 9' at Hillier; excellent bronze-red fall color; flowers single, 1 1/2" diameter, rich vibrant pink, flower pedicel and calyx darker red; witnessed in full flower at Wisley on March 20, 1998, one of the most spectacular flowering cherries.

'Spire' ('Hillier Spire')—Soft pink flowers on a fastigate tree, 27' high, 10' wide after 30 years; a sister seedling of 'Hillieri'; yellow, orange, red fall color; originated around 1935.

This is one of the most beautiful cherries in flower but does not appear to relish the Zone 7 and 8 heat. Plants at Milliken Arboretum have not performed well while *P. subhirtella* and *P. xyedoensis* have thrived. Perhaps 'Accolade', with its *P. subhirtella* parentage, would prove better adapted. The late Dr. Don Egolf, U.S. National Arboretum, produced several clones that have grown and flowered (rich pink) well in my Georgia trials. They show no signs of borer or canker injury. Study by Jacobs and Johnson, *HortScience* 31:988–991 (1996), showed *P. sargentii* seedlings the most susceptible to flooding; eight taxa were studied over the 1, 4, or 5 day flooding period. Native to Japan. Introduced 1890. Zone 4 to 7. Not reliable in Minnesota; Capiello reported no cold injury at Orono, ME.

Prunus serotina Ehrh. — Black Cherry

(prō'nus ser-ot'i-na)

LEAVES: Alternate, simple, oblong-ovate to lance-oblong, 2 to 5" long, 1 to 1 3/4" wide, acuminate, cuneate, serrulate with small incurved callous teeth, lustrous medium to dark green above, light green beneath and often villous along the midrib; petiole—1/4 to 1" long, glandular.

Prunus serotina is a common sight over much of the eastern United States. Distinctly pyramidal to conical in youth becoming oval-headed with pendulous branches, commonly growing 50 to 60' tall but occasionally reaching 100'. Tri-national champions are 112' by 78' in Perry County, IL, 132' by 51' in Great Smoky Mountains National Park, TN, and 85' by 61' in West Portsmouth, OH. The leaves are a lustrous dark green in summer and often a good yellow to red in fall. Leaves emerge early, often by late March in the Athens area. Flowers are white, 1/3" across, May (April, Athens), borne in pendulous, 4 to 6" long, 3/4" diameter racemes. Fruits are red, changing to black, 1/3" across, ripening in August and September and have a bitter-sweet and wine-like flavor and are used for making wine and jelly. Bark is gray-black and scaly on larger trunks. Valuable timber tree making its best growth on deep, moist, fertile soils but is also found growing on rather dry, gravelly, or sandy soils in the uplands. Still believe that cherry-crafted furniture is about the most beautiful of all woods. 'Spring Sparkle' has a dense growth habit with a decided weeping effect; abundance of white racemes in May–June, lustrous deep green leaves turn yellow to brilliant wine red in October; 35-year-old tree was 26' high and 22' wide, a Wandell introduction. Can be a troublesome pest in the garden because of weedy, aggressive nature. Ontario to North Dakota, Texas and Florida. Introduced 1629. Zone 3 to 9.

Prunus serrula Franch. — Paperbark Cherry

(prō'nus ser-ū-la)

LEAVES: Alternate, simple, lanceolate, 2 to 4" long, 1/2 to 1 1/4" wide, long acuminate, rounded, finely and regularly serrated, lustrous dark green and glabrous above, pubescent along midrib or in vein axils below, 9 to 15 vein pairs; petiole—1/4 to 1/2" long with 3 to 4 glands.

Prunus serrula is a small, pyramidal to rounded tree growing 20 to 30' high but seldom attains this size in the United States because of cankers and borers. The main ornamental asset is the glistening surface of the red-brown, mahogany-like bark which ultimately peels. Flowers are white, 2/3" diameter, produced in 2's and 3's, May, with the foliage. Fruit is a 1/2" long red drupe. Very difficult to find commercially but worth seeking. Handsome in winter when the bark is maximally exposed. When properly grown it makes a tree of great beauty. Magnificent in its finest form and the venerable specimen in Beth Chatto's garden is unforgettable. Mike Hayman, a plantsman of the first magnitude, and I wax poetic over this tree during every social visit. Do you remember . . . ? Central China. Introduced 1908. Zone 5 to 6. Also, *P. rufa* Hook. f., Himalayan Cherry, produces small clusters of pale pink flowers. Bark may be peeling, amber to reddish brown on the best forms. Grows 15 to 20' high. Zone 6 to 7; best in cool climates. Himalaya. Introduced 1897.

Prunus serrulata Lindl. — Japanese Flowering Cherry, Oriental Cherry

(prō'nus ser-ū-lā'ta)

LEAVES: Alternate, simple, ovate to ovate-lanceolate, rarely obovate, 2 to 5" long, 1 1/4 to 2 1/2" wide, abruptly long acuminate, cuneate or rounded, serrate or often serrate with aristate teeth, glabrous, reddish brown or bronze when unfolding, lustrous dark green; petiole—1/2 to 1" long, usually with 2 to 4 glands, glabrous.

Prunus serrulata is a large tree growing 50 to 75'; however, it is not a factor in the modern landscape for the numerous cultivars are much preferable. Most cultivars grow 20 to 25'(35') with a vase-shaped to rounded outline. The new foliage is often reddish tinged and eventually changes to lustrous dark green at maturity. Fall color is often a good bronze to subdued red. The flowers are greatly variable but range from single

to doubles, white to pinks, and from 1/2 to 2 1/2" diameter. They usually flower in April (mid-April, Athens) to early May and are borne profusely along the stems, usually before or with the leaves. They are usually grafted on *P. avium*, Mazzard Cherry, at heights of 4 to 6'.

The origin of many of the cultivars is lost to antiquity.

I suggest the reader consult Wyman, Bean, Ingram, Wilson, and most recently, *Japanese Flowering Cherries* by Wybe Kuitert and Arie Peterse, 1999, Timber Press, for detailed discussions. Although the cultivars are not all true selections from *P. serrulata*, they are often treated that way for convenience. Roland Jefferson,

"The Nomenclature of

Cultivated Japanese

Cherries (*Prunus*):

The Sato-Zakura

Group," details the complex

parentage. Also, expanded treatment in *The New RHS Dictionary of Gardening* that discusses many cultivated taxa.

'Amanogawa'—A form with the Lombardy Poplar type growth habit; flowers fragrant, pink, single to semi-double; sometimes developing the small black fruits; emerging leaves yellowish green; 20' high, 4 to 5' wide; not the most tidy columnar tree as branches are not very uniform in disposition.

Angel's Blush® ('Taizo')—Pink buds open to white flowers with a delicate pink blush, up to 30 petals per flower, open before and slightly with emerging bright green leaves; described as growing 6' high and 6' wide; discovered in a garden in Glendora, CA; introduced by Monrovia Growers.

'Daikoku'—Double (+40 petals), deep pink, throat with light pink tinge, 2" diameter; yellowish green new growth; open, spreading habit, 30'; Zone 5.

'Eugenzo'—2 1/2" diameter, rosy pink flowers fading to light pink, double with about 30 to 35 petals; leaves finely toothed, rich coppery colored when young; habit spreading with a rounded crown.

'Hokusai'—Heavy semi-double (up to 12 petals), 2" diameter, light pink to apricot; young leaves bronze, dark green and leathery at maturity, orange-red in fall; large rounded to spreading habit, 15 to 20' by 30 to 35'.

'Kofugen'—Double, deep pink; more stiffly upright and dense than 'Kwanzan', 25 to 30' by 15 to 18'; in essence similar to 'Kwanzan' but more upright in habit; Zone 5.

'Kwanzan' ('Kanzan', 'Sekiyama')—The most popular and probably hardiest of all the double types; deep pink, double (30 petals), 2 1/2" diameter flowers; very free-flowering and utilized abundantly from Boston to Atlanta for every conceivable purpose, full flower, early April 2007, Chapel Hill, NC; the new leaves are bronzy and may turn a good orange-bronze in fall; it is often grafted on *P. avium* about 4 to 6' high and ends up looking like a manufactured tree; I have observed it on streets, along walks, etc., and it provides the uniformity (more or less) that every landscape architect dreams about; when grown on its own roots it makes a 30 to 40' high and wide tree of great character and beauty; there was a splendid specimen on the Swarthmore campus; suffers from canker, virus and borers, often short lived; from recent literature I believe that 'Sekiyama' is the correct name with 'Kwanzan' sunk in synonymy; 'Kanzan' is listed as correct in RHS Plant Finder 2007–2008.

'Royal Burgundy' (PP 6,520)—A reddish purple leaf branch sport of 'Kwanzan', have observed in Georgia nurseries, indeed, new leaves and flowers are deeper red-purple; upright vase-shaped in youth, rounded with age, 20 to 25' by 15 to 20'; reasonable reddish orange fall color; slightly slower-growing than 'Kwanzan'; discovered by Frank Parks, Speer and Sons, Oregon.

'Shirofugen'—Flowers pink in bud, white when open but aging to pink, 30 petals; leaves deep bronze when young; flat-topped, wide-spreading crown, vigorous grower, I rate this one of the best forms.

'Shirotae' ('Mt. Fuji')—Pink in bud, open to white, fragrant, semi-double, 2" wide, produced early; leaves pale green with a slight bronze tinge in youth; spreading habit, often slightly pendulous, 15' by 20' or greater, Zone 5 to 7.

'Shogetsu' ('Shimidsu')—Double, 2" diameter, blush pink flowers lighten to pure white, 30 petals, 3 to 6 flowers in long-stalked corymbs; new leaves bronze-brown, serrations ending in long, thread-like bristles; rounded habit, 18', 15' by 20 to 25' at Hillier.

'Snowgoose' (*P. incisa* × *P. speciosa*)—Upright oval-rounded in youth to 20'; single white flowers before or with the bright green foliage; more pest resistant; has performed well in Zone 7.

'Taihaku' (Great White Cherry)—Single white, 2 to 2 1/2" diameter flowers; reddish bronze leaves when unfolding, up to 8" long, turning yellow-orange in fall; coarsely branched, broad inverted cone-shaped habit, 20 to 25', potentially to 40', slightly wider; Zone 5.

'Taoyame' ('Tao-yama')—Semi-double (up to 20 petals), soft shell pink; deep bronze emerging leaves; informal loose globe-like habit, 20' high and wide-spreading; Zone 5.

'Ukon'—Semi-double to double, large, 1 3/4" diameter, greenish yellow flowers; new growth supposedly reddish brown but photographs indicate more greenish than brown; 20' by 30'.

No doubt the oriental cherries are among the most beautiful of all spring flowering trees. Unfortunately, 'Kwanzan' dominates the market when many other fine forms are available. In Japan, these cherries are called 'Sato Zakura', meaning "domestic cherries." The literature tells me that the wood of *P. serrulata* is used for smoke-drying ham and bacon; leaves are used in cake making; see *Acta Horticulturae* 228:541–548 (1988). Interestingly, I perused many shade and ornamental tree nurseries and found only 'Amanogawa', 'Kwanzan', 'Shirofugen' and 'Shirotae' listed. Growers are now rooting cuttings with variable success but firm-wooded cuttings of 'Shirotae' collected in late June, 1,000 ppm KIBA, peat:perlite, mist rooted 22%. Long-winded, own-root protocol presented in *Amer. Nurseryman* 167(2):69–85 (1988). Japan, China, Korea. Zone 5 to 6 and south depending on the clone.

Prunus subhirtella Miq. — Higan Cherry, Spring Cherry, Rosebud Cherry

(prō'nus sub-hēr-tel'la)

LEAVES: Alternate, simple, ovate to oblong-ovate, 1 to 4" long, about 1/2 as wide, acuminate, cuneate, sharply and often doubly serrate, lustrous dark green above, pubescent on veins beneath, with about 10 pairs of veins; petiole—1/4" long, pubescent, glandular.

Prunus subhirtella is seldom cultivated in the species form but is represented by the types var. *pendula* (Maxim.) Tanaka and var. *autumnalis* Mak. These types grow 20 to 40' with a spread of 15 to 30' or more. 'Autumnalis' (var. *autumnalis*) has semi-double (10 petals) pink flowers about 3/4" in diameter which during a warm fall will open sporadically and then fully flower the following spring. Flowers are deep pink in bud, open to light pink and finally almost white. The habit on this tree is more like the species with forked trunk and erect twiggy branches with slender whip-like twigs. 'Autumnalis Rosea' has deeper pink flowers. 'Yae-shidare-higan' is a double (20 to 25 petals), pink-flowered type with pendulous branches and is quite floriferous with longer lasting flowers than var. *pendula*. The species is a very variable one giving rise to many different forms and flower colors. The variety *pendula*, (listed as *P. pendula* Maxim.), Weeping Higan Cherry, is usually grafted about 6' on the understock. The habit is gracefully weeping with single pink, 1/2" diameter flowers in March–April (mid to late March, Athens) before the leaves, borne in 2- to 5-flowered umbels. The fruits are oval-rounded, 1/3" diameter, red maturing to shining black. Variety *pendula* comes somewhat true from seed and selections such as 'Pendula Rosea' (pink flowers), 'Pendula Rubra' (deeper pink flowers), and 'Pendula Plena Rosea' (same as 'Yae-shidare-higan') have been selected. The double, pink, weeping forms are attractive and the flowers last longer than those of var. *pendula*. Pink Snow Showers™ ('Pisnshzam') has blushing pearl-pink, double flowers on a weeping 25' by 20 to 25' habit; fruits are 1/3" long, black drupes in minimal quantities; foliage is lustrous mint green; hardy to Zone 4; Lake County Nursery introduction; witnessed at J.F. Schmidt & Son in 2007, foliage was as good as advertised in late August; not sure of parentage but appears to fit herein; has better resistance to shot-hole disease than other weeping cultivars; 'Rosy Cloud' (same as 'Pink Cloud', PP 4,540) has large, double, beautiful, deep pink flowers, habit like 'Autumnalis', supposedly a cross between double weeping and 'Autumnalis', makes a good street or lawn tree. 'Scott Early' produces single pink flowers on a typical species habit; full flower March 23, 2008 at the Raulston, but

with more white than pink. 'Stellata' (perhaps same as Clarke's Spring Cherry) produces clearest shell pink petals, each flower up to 1 1/2" across, a 25-year-old tree at Hillier was 13' high and 20' wide, described by Lancaster, *The Garden* 120(5):240-241 (1995). 'Whitcomb' ('Whitcombii') is wide-spreading, horizontally branched with single, pink flowers that fade to white, grows 20 to 25' high, 30' wide. 'Winter Sun' is a weeping form, shorter and broader leaves than 'Rosea', later leaf drop, light pink flowers, longer flowering period, about two months earlier in winter, from Australia, see *Plant Varieties Journal* 3:31 (1990). Cherries are often described as short-lived and many fit that tenet; however, the *P. subhirtella* types are among the most cold, heat, and stress tolerant of the group. Once establish, they are long-lived, and offer the garden a sublime quality unavailable from other ornamental trees. I can conjure visions of superb trees in the East, Midwest, and South, especially var. *pendula* which even if it never flowered would be garden worthy. Variety *pendula* might be likened to poor man's Weeping European Beech, with the artistically weeping gray-brown prominent horizontally lenticelled branches. Growth rate is extremely fast and one does not have to wait until retirement to appreciate the ornamental virtues. The various cultivars can be rooted from firm wood cuttings in June and July. Japan. Introduced 1894. Zone (4)5 to 8. In Orono, ME, 'Autumnalis' suffered only tip injury while var. *pendula* was killed outright. Have observed pendulous seedlings in wood's edges, and non-cultivated areas that were obviously bird-planted.

Prunus tenella Batsch — Dwarf Russian Almond

(prö'nus te-nel'a)

LEAVES: Alternate, simple, obovate or oblong, 1 1/2 to 3 1/2" long, 1/2 to 1" wide, acute, saw-toothed, lustrous dark green above, pale beneath, glabrous; petiole—1/6" long.

Prunus tenella is a low, suckering shrub that may grow 2 to 5' high. The principal value resides in the rosy red, 1/2" wide flowers that occur singly or up to 3 from each bud of the previous year's growth. 'Alba' has white flowers and light green leaves; 'Gessleriana' (f. *gessleriana* (Kirchn.) Rehder) has red-budded, bright pink, almost 1" diameter flowers; and 'Fire Hill', which has been offered commercially in the United States, has intense red flowers on a short-statured, 2 to 2 1/2' high plant. These plants may be short-lived in American gardens. Have experienced 'Fire Hill' at Wisley just as it was coming into flower; full flower at Wisley April 14, 1999, a potent red on naked stems. Rather weak shrub but the petal color was intense red. 'Fire Hill' was killed outright in Maine. 'Ruth's 100' has a compact habit, profuse flowering, drought tolerant. Forma *georgica* at Hillier was 15 to 20' high, larger leaves, and white flowers March 5, 1999. I did not know any *P. tenella* taxon grew so large. Southeastern Europe, western Asia to eastern Siberia. Introduced 1683. Zone 2 to 6.

Prunus tomentosa Thunb. — Manchu Cherry, Nanking Cherry

(prö'nus tō-men-tō'sa)

LEAVES: Alternate, simple, obovate to elliptic, 2 to 3" long, 3/4 to 1 1/2" wide, abruptly acuminate, cuneate, unequally serrate, rugose, dull dark green and pubescent above, densely villous beneath; petiole—1/12 to 1/6" long, glandular.

STEM: Covered with a soft villous pubescence.

Prunus tomentosa is a broad-spreading, densely twiggy shrub, becoming more open, irregular and picturesque with age. It grows 6 to 10' high and spreads to 15'. The bark is shiny, reddish brown and exfoliating. Leaves are dark green in summer and extremely tomentose on the lower surface. The flowers are pinkish in bud changing to white, fragrant, 3/4" across; early to mid-April; one of the earliest flowering *Prunus* species. The fruits are scarlet, 1/3" across, edible, ripening in June through July. Could be used in mass plantings or the shrub border for the early flowers and fruits are valuable. 'Leucocarpa' has white flowers and white fruits. 'Orient' has large orange-red fruits. Seeds require about 2 months cold. North and western China, Korea, Himalaya, Japan. Cultivated 1870. Zone 3 to 7?

Prunus triloba Lindl. 'Multiplex' — Double Flowering Plum, Flowering Almond

(prō'nus trī-lō'ba mul' ti-pleks)

LEAVES: Alternate, simple, broad-elliptic to obovate, 1 to 2 1/2" long, 3/4 to 1 1/4" wide, acuminate or sometimes 3-lobed at apex, broad cuneate at base, coarsely and double serrate, medium green above, slightly pubescent beneath; petiole—1/2" long, often with thread-like stipules.

Prunus triloba 'Multiplex' is a large (12 to 15'), cumbersome, clumsy shrub with tree-like qualities. The foliage is medium green in summer and turns yellow to bronze in fall. The flowers are double, pinkish, about 1 to 1 1/2" across, borne in April. They are often nipped by a late freeze and severely injured. I have never seen any fruit on

the plants. This species has always been somewhat confusing. Rehder listed the double-flowered type as *P. t.* var. *multiplex* and noted this was or is the original *P. triloba*. *Prunus t.* var. *simplex* (Bge.) Rehd., f. is the single-flowered species type and bears 1/2" diameter, downy, globose, red fruits. When right the flowers are rather impressive but it has nothing to recommend it beyond this. Introduced from China in 1885. Zone 3 to 6(7).

*Prunus virginiana* L. — Common Chokecherry

(prō'nus vēr-jin-ē-ā'na)

LEAVES: Alternate, simple, broad-elliptic to obovate, 1 1/2 to 5" long, two-third's as wide, abruptly acuminate, broad-cuneate to rounded at base, closely serrulate, dark green above, glaucescent or grayish green beneath, glabrous except axillary tufts of hair; petiole—1/2 to 3/4" long, glandular.

Prunus virginiana can grow 20 to 30' tall with a spread of 18 to 25'. National champion is 55' by 93' in Baltimore County, MD. It is a small, suckering tree or large shrub with crooked branches and slender twigs forming an oval-rounded crown. Flowers are white, 1/3 to 2/5" across; late April–May; in 3 to 6" long, 1" wide racemes. Fruit is red, finally dark purple, round, 1/3" across. The fruits have been used for making jams, jellies, pies, sauces and wine. 'Schubert' is of pyramidal habit with dense foliage, green at first, and finally changing to reddish purple. 'Canada Red' is a branch sport of 'Schubert' with faster growth rate, straighter trunk, well-distributed branches, full-rounded crown, brighter red leaves, Bailey Nursery introduction; I always considered this a synonym of 'Schubert'. Also listed are:

'Boughen's Chokeless'—Non-astringent fruit.

'Boughen's Yellow'—Large, yellow fruits.

'Canada Red Improved'—Schmidt selection from 'Canada Red' as a faster growing sport; oval form, with more upright central leader.

'Copper Schubert'—Similar in size to 'Schubert' but produces copper-green leaves and non-astringent, red fruits.

'Mini-Schubert'—Compact, upright-oval habit, interior branches small and upright, mature leaf color reddish purple.

'Robert'—Large shrub with red-purple leaves, compact inflorescences, large fruits; see *HortScience* 30:445 (1995).

On the coast of Maine, the species grows in rock crevices, sandy soils, and no soil, exposed to salt-air inundations. Remarkable dry-soil tolerance with copious quantities of red to black fruits in late summer and relatively healthy foliage. Newfoundland, to Saskatchewan, North Dakota, Nebraska, south to North Carolina, Missouri and Kansas. Introduced 1724. Zone 2 to 6.

Prunus xyedoensis Matsum. — Yoshino Cherry

(prö'nus yed-ō-en' sis)

LEAVES: Alternate, simple, oval, broadly ovate to obovate, 2 1/2 to 4 1/2" long, 1 1/2 to 2 1/2" wide, narrowed to a slender point at apex, rounded or broadly wedge-shaped at base, doubly serrate, dark green and glabrous above, downy on midrib and veins below.

Prunus xyedoensis is rather difficult to pin down as to exact parentage and origin. I have seen it listed as a *P. serrulata* × *P. subhirtella* hybrid but also *P. speciosa* × *P. subhirtella*. It is a plant of great beauty for the slightly fragrant, pink or white, 1 to 1 1/2" diameter flowers occur in racemes of 4 or more usually before, sometimes with, the leaves in March–April. Full flower in Dirr garden on March 23, 2002 and March 22, 2003. The habit is rounded, spreading, 20 to 30' high, potentially 40 to 50' high. Fruits are globose, 1/2" diameter, shining black drupes.

'Afterglow' (PP 5,730)—Handsome pink-flowered form that originated as a seedling from 'Akebono'; habit is upright-spreading, 25' by 25'; glossy bright green summer foliage followed by yellowish fall color.

'Akebono' ('Daybreak')—Soft pink, single flowers in late March and forms a rounded, spreading, 25' high and 25' wide tree; put into commerce by W.B. Clarke of California; has been outstanding at Milliken Arboretum, with pink flowers fading to white, rapid growth and almost full leaf retention into early November.

Cascade Snow™ ('Berry')—Pure white flowers, followed by clean dark green foliage that changes yellowish to bronze-orange in autumn; 25' by 20'; this cultivar is more resistant to the common flower and foliage diseases that plague ornamental cherries; Schmidt Nursery introduction.

'Ivensii'—Distinct weeping form with white, slightly fragrant flowers; the habit is almost broad umbrella-shaped with the ribs (branches) cascading to the ground to form a large mound; the first time I saw the plant in England I thought it was a form of *P. subhirtella*, later at Kew Gardens another specimen jumped in my path, a virtual carbon copy of the first; does not grow as large or wild as 'Shidare-yoshino'; a seedling of *P. xyedoensis* raised by Hillier in 1925.

'Pink Shell'—Shell-pink petals that fade to a lighter shade.

'Snow Fountains' ('White Fountain' by Wayside)—Might be best included under *P. xyedoensis* although I do not know the exact parentage; the habit is semi-weeping with snow white flowers on naked stems; will grow 6 to 12' high and wide at maturity; foliage is dark green and turns lovely gold and orange hues in fall; may produce a few black fruits.

'Shidare-yoshino' ('Shidare Yoshino') (f. *perpendens*)—Weeping form and often called Weeping Yoshino Cherry; an 18-year-old plant in the University's Botanical Garden was 20' tall and 30' wide with wildly arching branches; the plant is beautiful when covered with masses of white flowers in late March.

'Tsubame'—Grew at Wisley with spreading, arching branches, not truly weeping, and white flowers.

'Washi-no-o'—At the Arnold Arboretum was spectacular in white floral regalia.

'Yoshino Pink Form'—Flowers of a charming pink shade that open later than 'Pink Shell'.

Seeds require a 2-month cold period and softwood cuttings are being rooted in abundance. The weeping form is usually staked and at a certain height allowed to weep. Quite adaptable and although flowering is most profuse in full sun, a respectable display occurs in partial shade (pine shade). This is the species that graces the Tidal Basin in Washington, DC, and allows Macon, GA, to host the cherry blossom festival. It is terrifically fast growing as a young tree and 3- to 4-year-old nursery trees might have 3 to 4" diameter trunks. Found in Japan as a cultivated tree. Noted 'Somei-Yoshino' was utilized as the name for the typical species type. Introduced 1902. Zone 5 to 8.

Pseudocydonia sinensis (Thouin) C.K. Schneid. (*Cydonia sinensis* Thouin) — Chinese Quince
(sō-dō-sī-dō'ni-a sī-nen'sis)

FAMILY: Rosaceae

LEAVES: Alternate, simple, obovate, ovate or oval, 2 1/2 to 4 1/2" long, 1 1/2 to 2 1/2" wide, acute, cuneate, covered with pale brown hairs beneath at least when young, margin regularly and minutely serrate, teeth gland-tipped, leathery lustrous dark green above, glabrous, pale green below, with spreading hairs on principal veins, midvein impressed; petiole—1/2" long, grooved, with distinct raised bristly glands.

BUDS: Small, 1/8" long, imbricate, 3-scaled, glabrous.

STEM: Slender, lustrous brown, hairy when young, glabrous, at maturity epidermal skin peeling off, few lenticels.

SIZE: 10 to 20'(30 to 40') high; one-half to two-third's that in spread.

HARDINESS: Zone 5 to 6 and into Zone 7; National, Tyler, Coker, and Morris Arboreta have notable specimens.

HABIT: Distinctly dense, upright-branching small tree or large shrub forming an oval to oval-rounded outline.

RATE: Slow-medium.

TEXTURE: Medium.

BARK: Quite beautiful, flaking off to produce a mosaic not unlike that of the Planetree and Chinese Elm; trees I have observed also developed a fluted trunk; the bark alone is sufficient justification for using this plant; colors range from gray, green to brown; bark exfoliates on 2 to 3" diameter trunks.

LEAF COLOR: Leaves out early and I have observed emerging leaves in late February on the Georgia campus, turns lustrous dark green, yellow to red in fall.

FLOWERS: Perfect, soft to deep pink, 1 to 1 1/2" across, solitary, sessile, borne on year-old shoots with the leaves, April–May.

FRUIT: A large, 5 to 7" long, egg-shaped, citron-yellow pome, October, highly aromatic, fruits developed the third year after planting in the Horticultural Garden; numerous fruits on Athens plants fall to ground almost like yellow cantaloupes among the grass.

CULTURE: Moist, acid, well-drained soil; site in full sun; microclimatize as much as possible especially in North.

DISEASES AND INSECTS: Fireblight is a major problem; trees were devastated by fireblight and had to be removed from campus.

LANDSCAPE VALUE: Excellent plant for bark effect; not extensively cultivated in the United States; excellent for winter effect; beautiful specimen, accent or in groupings.

PROPAGATION: Seed required a cold period of 2 to 3 months, seeds extracted from fruits that had been kept in a cooler during winter germinated immediately upon planting.

ADDITIONAL NOTES: Branches spineless which separate it from *Chaenomeles* species. Not common in cultivation. Bark is very attractive. A red-fruited cultivar has been described. Best specimen I have seen is at Tyler Arboretum, Lima, PA. Great grouping (3) of multi-stemmed or low-branched plants now 30' by 25' at Coker Arboretum. Beautiful bark; flower colors are different shades of pink/rose on each plant. Not common in commerce but unique by virtue of foliage, fruit and bark. For the collector. Fruits can be utilized to make jelly.

NATIVE HABITAT: China. Introduced about 1800.

Fruit

Pseudolarix amabilis (J. Nels.) Rehd. (*P. kaempferi* (Lamb.) Carr.) — Golden-larch
(sō-dō-lar'iks a-mab'a-lis)

FAMILY: Pinaceae

LEAVES: Scattered and spreading, often curved, 1 1/2 to 2 1/2" long, 1/12 to 1/6" wide, apex long-pointed, soft, light green and rounded above, keeled beneath, margins thin with 2 conspicuous gray bands of stomata, singly and spirally on long shoots, in a radiating cluster on spur-like branches.

BUDS: Of long shoots ovoid, pointed, surrounded by long-pointed, brown scales with free tips which fall away soon after the leaves develop in spring; of short shoots similar in shape with persistent scales; axillary buds rounded with short-pointed deciduous scales.

STEM: Two types: long shoots thin, smooth, bloomy, brown in the second year, roughened by permanent bases of fallen leaves; short spurs longer than those of *Larix*, with a distinct constriction between the annual rings, with 15 to 30 umbelliformly spreading leaves at the end.

SIZE: 30 to 50' in height, spreading to 20 to 40'; can grow to 120'.

HARDINESS: Zone (4)5 to 7; respectable 30 to 40' specimen at the Raulston, Zone 7.

HABIT: Broad-pyramidal, deciduous conifer with wide-spreading horizontal branches and a rather open habit at maturity; I had a small (6') specimen in my Illinois garden which was already quite open; Wyman noted that trees up to 30 to 40' high may be almost as wide as tall; in some respects resemble a mature *Cedrus* in habit; wonderful venerable specimens of *Cedrus libani*-like habit at the Arnold Arboretum.

RATE: Slow, in fact a 100-year-old tree was only 45' tall.

TEXTURE: Medium.

BARK: On old trunks grayish to reddish brown and lightly ridged-and-furrowed with rather broad ridges.

LEAF COLOR: Soft, light green above, bluish green beneath in summer turning a clear golden yellow (orange-yellow) in autumn; fall color is brief but it is fantastic; peaked on October 16, 1978 at Arnold and was essentially gone by October 24; peak fall color early November, Raulston Arboretum.

FLOWERS: Monoecious, borne on separate branches of the same tree, opening in May or June; male flowers yellow in densely clustered catkins; females solitary.

FRUIT: Cones solitary, ovoid, erect, 2 to 3" long, 1 1/2 to 2" wide, ripening in autumn of the first year; glaucous, bloomy, rich green to purplish during summer, ripening to golden brown, very beautiful but often borne in the upper reaches of the tree so as to be reduced in ornamental effectiveness; shattering soon after maturity.

CULTURE: Transplants readily balled-and-burlapped or from a container; requires a light, moist, acid, deep, well-drained soil; does not effectively tolerate high pH soils; prefers full sun although I have seen it in partially shaded situations; protect from wind; somewhat resistant to air pollutants.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Truly a beautiful specimen in large areas; grows slowly enough that it can be integrated into the small landscape; the cones and fall color add seasonal interest; several magnificent trees along Bussey Brook in the Arnold Arboretum that are possibly the finest specimens in the country; reasonable heat adaptability to at least Zone 7, compared to *Larix* species; added a plant to our Chapel Hill garden which was just leafing on April 13, 2007.

CULTIVARS:

'Annesleyana'—Dwarf, bushy; short, horizontal, pendent branches; leaves densely set; several other dwarf forms 'Dawsonii' and 'Nana' are described but I have not seen them.

'Pendula'—Yes, at Knightshayes in England; somewhat arching branches, July 13, 1999.

PROPAGATION: Seeds are the usual method of reproduction; however, it is difficult to obtain fertile seeds. A specimen at the Missouri Botanic Garden has coned rather heavily but no viable seed has been produced. Den Ouden and Boom and Dallimore and Jackson noted that seeds were difficult to obtain from China in a fresh state, but fertile seeds were frequently produced on trees grown in Italy. On a 1976 trip to the Holden Arboretum, Dick Munson, the former propagator, showed me numerous seedlings he had grown from seed collected off a grove of trees in Mentor, OH. He was kind enough to show me the parent trees and needless to say I was impressed. We discussed the problems of seed propagation and theorized that the trees are self-sterile and the fact that several seedling-grown trees were in close proximity contributed to cross-pollination and viable seed production. Perhaps this is the reason the tree in the Missouri Botanic Garden does not develop viable seed. Seeds may germinate without pretreatment, but 60 days at 41°F will result in more uniform germination; trees in the Arnold Arboretum produce abundant viable seeds.

ADDITIONAL NOTES: Spectacular in fresh green spring foliage and in golden yellow fall color. The great trees at the Arnold Arboretum are the standards by which all other specimens are judged. If one did not know better, these trees could be mistaken for Cedar-of-Lebanon.

NATIVE HABITAT: Eastern China at altitudes of 3,000 to 4,000'. Introduced 1852 by Robert Fortune.

Pseudotsuga menziesii (Mirb.) Franco — Douglasfir (formerly listed as *P. douglasii* (Sabine ex D. Don) Carr. and *P. taxifolia* (Lamb.) Britt.)

(sö-dō-sö'ga men-zē'zē-ī)

FAMILY: Pinaceae

LEAVES: Pectinate with a V-shaped arrangement between the 2 lateral sets, straight, 1 to 1 1/2" long, thin, shining green, gray-green, blue-green, to blue above, with 2 white bands of stomata beneath, smelling of camphor when bruised.

BUDS: Ovoid-conical, imbricate, apex pointed, 1/4 to 1/3" long, shining chestnut brown, mostly resinous at base.

STEM: Yellowish green initially, becoming gray to brown, minutely pubescent or almost glabrous.

CONES: Three to 4" long, 1 1/2 to 2" wide, light brown, bracts are prominent and extend beyond the scales, persistent into winter.

SIZE: Under landscape conditions will grow 40 to 80' in height with a 12 to 20' spread; can grow to 200' and greater in its native habitat; co-national champions var. *menziesii* are 281' by 71' in Olympic National Forest, WA and 301' by 65' in Jedediah Smith Redwood State Park, CA.

HARDINESS: Zone (3)4 to 6, depending on the seed source; there is a 30' high tree on the Georgia campus (Zone 7) but it is not particularly vigorous.

HABIT: An open, spired pyramid with straight stiff branches; the lower drooping, upper ascending; dense in youth becoming loose with age.

RATE: Medium, will grow 12 to 15' over a 10 year period; this rate based on observations taken with trees growing on University of Illinois campus; one authority noted that the tree might grow 40 to 100' high after 50 to 75 years and 1 to 2' a year when young; he leaves a pretty safe estimating range!

TEXTURE: Medium.

BARK: On young stems smooth except for resin blisters; on old trunks often divided into thick, reddish brown, corky ridges separated by deep irregular fissures; becoming 6 to 24" thick.

LEAF COLOR: Depends largely on the seed source; the Rocky Mountain, Colorado type (var. *glauca*) is bluish green and hardy in Zone 4, this is the type which should be grown in the North; the other type (var. *menziesii*) is restricted to the Pacific slope where there is ample atmospheric moisture; this type has dark green foliage and is less hardy (Zone 6); this type is the largest growing and can grow to 300' and more; types with yellow-green needles exist.

FLOWERS: Monoecious, on 2-year-old wood; staminate axillary, pendulous; pistillate terminal, with exerted, 3-pointed bracts, handsome rose-red when young.

FRUIT: Cones pendulous, oval-ovoid, 3 to 4" long by 1 1/2 to 2" broad, 3-pronged bracts, light brown.

CULTURE: Transplants well balled-and-burlapped; prefers neutral or slightly acid, well-drained, moist soils; fails on dry, poor soils; sunny, open, roomy conditions; injured by high winds; does best where there is an abundance of atmospheric moisture.

DISEASES AND INSECTS: Cankers (a number of species), leaf casts (similar to leaf spots), leaf and twig blight, needle blight, "witches' broom", aphids, adelgid, Douglasfir bark beetle, eastern pine shoot borer, bagworm, scales, spruce budworm, pine butterfly, Zimmerman pine moth, tussock moth, gypsy moth, and strawberry root weevil.

LANDSCAPE VALUE: One of the noblest forest trees, very ornamental under cultivation; an excellent specimen, grouping or mass; not suited for underplanting or windbreaks; its use should be tempered in the dry windy areas of the Midwest; makes a nice short needle Christmas tree; noble specimens in the Portland, OR area, particularly handsome in the Queen Elizabeth Park where they mingle with *Calocedrus decurrens* and *Thuja plicata*; safe to state not for the small property unless one of the dwarfish cultivars are used.

CULTIVARS: Probably 30 to 40 cultivars with very few available except from specialty growers. Thirty-one cultivars featured in *Conifers*. Stanley and Sons lists 32 taxa in their 2007–2008 catalog. Worth a look as the variation is amazing. Twenty-one taxa described and/or illustrated in Bitner, 2007.

'Fastigiata'—Distinctly ascending, spire-like, branches crowded, branchlets erect, needles green with a hint of gray, densely radial, short; good looking clone; Dawes Arboretum, Newark, OH had several beautiful specimens.

'Fletcheri'—I suspect the most popular dwarf form with blue-green, 1/2 to 3/4" long needles and spreading, flat-topped, compact habit, 2 to 2 1/2' by 2 1/2 to 3', will grow 6' high and slightly wider at maturity.

var. *glauca* (Beissn.) Franco—More compact with slightly more ascending branches than the species; leaves bluish green; cones 2 to 3" long with reflexed bracts; hardy to Zone 4.

'Pendula'—Branches and branchlets held close to the stem and hanging like curtains; not particularly attractive.

PROPAGATION: Several papers on rooting Douglasfir discuss various factors related to successful rooting and would make interesting reading for propagators. See *J. Amer. Soc. Hort. Sci.* 99:551–555 (1974); *The Plant Propagator* 24(2):9 (1978); *Proc. Intl. Plant Prop. Soc.* 28:32 (1978); and *Proc. Intl. Plant Prop. Soc.* 43:284–288 (1993). Seeds will germinate without pretreatment although this may vary with seed source.

ADDITIONAL NOTES: There is considerable confusion related to the various types of Douglasfir and every individual tells a different story. The following information is based on the thinking of the foresters and coincides pretty well with what most knowledgeable plantsmen relate. *Pseudotsuga menziesii* includes two geographic varieties: (1) the Coast Douglasfir (var. *menziesii*) is fast-growing, long-lived, and sometimes becomes over 300' tall and attains a diameter of 8 to 10'. The foliage is typically of a yellow-green color, although some trees show bluish green, and the cones are often 4" long and have straight, more or less appressed bracts; (2) the Rocky Mountain Douglasfir (var. *glauca*) is slower growing, shorter lived, and seldom exceeds 130' in height. The national champion is 84' by 41' in Buncombe, NC. The foliage is bluish green but others with yellowish green needles are found standing together. The cones are smaller,

barely 3" in length, with much-exserted and strongly reflexed bracts. Unfortunately, in certain areas the two varieties overlap and here intermediate forms are found. Variety *glauca* is widely grown and used for Christmas trees and ornamental plantings in the midwestern and northeastern United States.

At one time, the most important lumber producing tree in the United States. The wood has exceptional strength and is widely used for heavy structural timber; also used for plywood and pulp. One of the best short-needled Christmas trees because the needles do not easily fall off as is the case with *Abies* (fir) and *Picea* (spruce).

Visited the Pacific Northwest on several occasions and upon reflection cannot remember witnessing anything but healthy, vigorous specimens. Took a cable car up a mountain outside Vancouver, British Columbia and the entire mountainside down to the Fraser River was seemingly nothing but *P. menziesii*. Also, in Van Dusen Garden, Vancouver, old isolated specimens and groupings provide stability to the fine garden. The old heads are often irregular-conical with long, slender boles.

Recommended reading for the taxonophile is "The Identity Crisis of the Douglasfir," in *The New Plantsman* 1(1):20–28 (1994). Before becoming *Pseudotsuga menziesii* (Mirb.) Franco in 1990, 20 other names were given since *Pinus taxifolia* Lamb. in 1803. Who said taxonomy was dead? The species has more aliases than the world's worst criminal. For even more fun, check GRIN for a nauseating experience.

Have seen *P. xichangense*, *P. macrocarpa* (Vasey) Mayr. With 2-ranked needles, large cones and *P. wilsoniana* Hay. (is now *P. sinensis* Dode.) with Chinafir-like prickly needles in England. Have a plant of *P. sinensis* and the blue-green needles are much longer and more prickly than *P. menziesii*.

NATIVE HABITAT: Rocky Mountains and Pacific coast (British Columbia to Mexico). Introduced 1827.

Ptelea trifoliata L. — Hoptree, also called Wafer-ash, Stinking-ash or Water-ash

(tē'lē-a trī-fō-li-ā'ta)

FAMILY: Rutaceae

LEAVES: Alternate, trifoliate, leaflets ovate to elliptic-oblong, 2 1/2 to 5" long, narrowed at ends, sometimes acuminate, middle largest with a short petiolule, the lateral ones oblique at base, smaller, entire, or obscurely crenulate, sessile, lustrous dark green above and glabrous below; if viewed with a hand lens while back-lighted distinct oil-glands are evident; pungent when bruised; petiole—2 to 4" long.

BUDS: Closely superposed in pairs, very low-conical, sessile, hidden beneath petiole bases, breaking through the leaf scars, not distinctly scaly, silvery silky; terminal lacking.

STEM: Glabrous, buff to reddish brown, moderate, warty and dotted, terete; pith rather large, roundish, continuous, white; leaf scars somewhat raised, rather long, horseshoe-shaped when torn by buds; 3 bundle traces.

SIZE: 15 to 20' high and as wide, often 5 to 15' high.

HARDINESS: Zone 3 to 9.

HABIT: Large shrub or small tree of a bushy, rounded nature; if tree-like usually low-branched; has a tendency to sucker.

RATE: Slow to medium.

TEXTURE: Medium in leaf, medium-coarse in winter.

BARK: Dark gray, smooth, except for warty protuberances.

LEAF COLOR: Lustrous dark green in summer, yellow-green in fall; have observed good yellow on selected plants.

FLOWERS: Small, unisexual, greenish white, 1/3 to 1/2" diameter, fragrant, borne in terminal, 2 to 3" diameter corymbs (panicle?) on short lateral branches, late May–June, not particularly showy.

FRUIT: A compressed, broadly winged, suborbicular, 2-sided, 2/3 to 1" diameter, indehiscent samara; brownish at maturity, rather conspicuous; effective August through September; the common name is derived from the shape and appearance of the parts; may persist into December and later.

CULTURE: Very adaptable species which performs maximally in well-drained soils; sun or shade; found in rocky woods, better drained lowlands, and moist woodlands as an understory plant and for that reason makes a good choice for planting in heavy shade; I have seen plants in full sun and heavy shade and, in both situations, they made handsome specimens.

DISEASES AND INSECTS: Various leaf spots and a rust disease; none of which are serious.

LANDSCAPE VALUE: An interesting native plant covering much of the eastern United States; the cultivar 'Aurea' is effective in the shrub border; this plant can grow on one after a while; I have developed a rather curious fondness for the species.

CULTIVARS:

'Aurea'—Quite a striking form with rich yellow young leaves fading to lime green by August; not as obtrusive as many yellow-foliaged plants because the color subsides with time; can be rooted from softwood cuttings treated with 8,000 ppm IBA-talc, also comes 90% true from seed to the yellow-foliage characteristics; this form originated in the late 19th century on a nursery in Duerrgoy; Lancaster, *The Garden* 120(1):12–13 (1995), provides a great synopsis.

'Fastigiata'—An upright form, branches erect; a 25' high plant grew at Hillier, 1999.

'Glaucua'—Leaves blue-green and quite striking compared to the normal lustrous dark green leaves.

subsp. *polyadenia* (Greene) V. L. Bailey—Mountain and western form that remains a small shrub but fruits heavily.

PROPAGATION: Seed requires a 3 to 4 month cold period; cuttings can be rooted with good success when collected in June–July and treated with 8,000 ppm IBA-talc, mist; dug a plant from the wild for my garden and watched it grow like topsy in its new home; moved it again and watched numerous shoots developing from remaining roots; this suggests root cuttings would work quite well.

ADDITIONAL NOTES: The fruits have been used as a substitute for hops; hence, the reason for the first common name. The bark has been utilized in medical preparations. The fruits and bark contain a bitter substance and the stems when bruised are rather pungent.

NATIVE HABITAT: Ontario and New York to Florida, west to Minnesota, southern Colorado, Arizona, south into southern Mexico. Introduced 1724.

Pterocarya fraxinifolia (Lam.) Spach — Caucasian Wingnut

(tēr-ō-kā'ri-a frak-si-ni-fō'li-a)

FAMILY: Juglandaceae

LEAVES: Alternate, pinnately compound, 8 to 18" long, leaflets 7 to 27, ovate-oblong to oblong-lanceolate, acuminate, rounded, sharply serrate, 3 to 5" long, thin, glabrous except stellate hairs in the axils and along the midrib beneath, shiny, handsome dark green; rachis terete, glabrous.

BUDS: Red-brown, rather large, superposed, the upper distinctly stalked or elongating the first year, naked with folded leaves.

STEM: Red-brown, moderate or rather stout, rounded, glabrous; pith moderate, angular, chambered with rather close thin light brown plates; leaf scars elliptical or 3-lobed, large, rather low; 3 bundle traces, crescent- or horseshoe-shaped, crenated or fragmented.

SIZE: 30 to 50' in height with a similar spread, can grow to 90', 115' high specimen is known; 160-year-old-tree at Abbotsbury Garden in 1999.

HARDINESS: Zone (5)6 to 8(9); none of the species are completely hardy at the Morton Arboretum which suggests that temperatures below –20°F will kill stems and branches.

HABIT: Broad-spreading, rounded, often with several stems near the base; can be a beautiful tree with wide-spreading branches; has a tendency to sucker.

RATE: Medium, 12 to 15' over a 10 year period.

TEXTURE: Medium in leaf and winter habit.

LEAF COLOR: Dark glossy green in summer, excellent summer foliage and apparently quite free of insects and diseases; fall

color is yellow-green; plants in Zone 7 have produced no fall coloration; young leaves can be injured by frost.

FLOWERS: Monoecious; male in greenish catkins to 5" long; female to 20" long, catkin-like, May–June.

FRUIT: Winged nut(let), reminds of a wing nut, wings 3/4" diameter, roundish, oblique, horned at the top, green changing to brown, ripening in September–October; interesting as they hang on a slender, pendent, 12 to 20" long spike.

CULTURE: Transplant balled-and-burlapped into moist, well-drained soil deep enough to accommodate the extensive root system; full sun; pH adaptable; will tolerate wind, drought and hard soil if the roots are well-established; prune in summer; in the wild found in moist soil and there makes its best growth.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Very handsome specimen plant which could be successfully used for large areas such as parks, schools, and golf courses; the largest specimen I have seen was very broad-spreading and made an excellent shade tree; much superior to ashes, honeylocusts and weak-wooded maples but little known; handsome foliage and interesting fruits that are not particularly messy; suspect suckering would limit landscape potential.

PROPAGATION: If seed is fresh some germination will take place upon sowing; as seed dries a period of cold (2 to 3 months) is probably necessary to insure uniform germination; I noticed that seeds from Arnold Arboretum trees were largely void while seeds from trees at the University's Botanical Garden were solid; this could be related to the length of the growing season and summer heat; cuttings taken in summer and made from young shoots with a heel will sometimes root; probably best to collect cuttings in July and treat with high IBA concentration; the species shows a propensity to sucker which would indicate that root cuttings are a possibility.

ADDITIONAL NOTES: I first saw this at Vineland Station, Ontario, Canada, during a meeting of the American Society for Horticultural Science. No one could correctly identify the species until Dr. Lumis of the University of Guelph told us the identity. It was a massive, spreading specimen of great beauty. The root system is aggressive and the tree probably does not deserve consideration for residential or street use but in parks and large areas especially with abundant foot traffic, it might be utilized. I have observed the species or those treated under RELATED SPECIES in European gardens, particularly in Germany where plants are quite common.

Wood is similar in appearance to walnut and mechanical properties are similar to those of Black Poplar. In southern Russia used in a wide range of interior furnishing, furniture, and packaging. Intergeneric hybrids between *Pterocarya* and *Juglans* were constituted, see *J. Amer. Soc. Hort. Sci.* 111:627–630 (1986).

NATIVE HABITAT: Caucasus to northern Iran. Introduced 1782.

RELATED SPECIES: I have doubts as to the correct identity of many of the specimens I have seen labeled as *P. fraxinifolia*. Many appear to be *P. xrehderiana* or *P. stenoptera*.

Pterocarya xrehderiana C.K. Schneid., (r-ō-kā'ri-a rā-dēr-ē-ā'na), Rehder Wingnut, is a hybrid between *P. stenoptera* and *P. fraxinifolia*. Leaflets number 11 to 21, 2 to 5" long, narrow-oblong. Raised at the Arnold Arboretum from seeds received in 1879 from Lavalley's collection of Segrez. It is a rapid grower and tends to be prolific in its production of suckers. The rachis is winged but nowhere to the degree of *P. stenoptera* and not toothed. Apparently more vigorous and hardy than either parent. Observed a cut-leaf form, the leaflets deeply and delicately lobed, reminding of the Cutleaf Walnut, but divisions not as fine; Pat McCracken had a small plant in his garden in Zebulon, NC called 'Fern Leaf' but I don't know the legitimacy of the name. Freeze of April 6 and 7, 2007 killed the plant. Early leafing and cambial activity, coupled with lows in the 20s, spelled doom. Listed as a cultivar of *P. stenoptera* in RHS Plant Finder 2008–2009. Zone (5) 6 to 8.

Pterocarya rhoifolia Sieb. & Zucc., (tēr-ō-kā'ri-a rō-i-fō'lē-a), Japanese Wingnut, carries 8 to 16" long leaves with 11 to 21 leaflets, each 2 1/2 to 4" long, 1 to 1 1/2" wide, acuminate, rounded, finely and evenly toothed and dark green. The rachis is not winged. Differs from other species mentioned because buds have 2 to 3 large covering scales. Japan. Introduced 1888. Zone 6 to 8?

Pterocarya stenoptera C. DC., (tēr-ō-kā'ri-a sten-op'tēr-a), Chinese Wingnut, has 11 to 21(25) leaflets which are oblong or narrowly oval, finely and regularly toothed, 2 to 5" long, and 1/3 to 2" wide, entire leaf 10 to 16" long. The significant difference between this and *P. fraxinifolia* is the winged rachis with the wings sparsely toothed. Most Wingnuts I have seen show the winged character which indicates that they are not *P. fraxinifolia* although usually labeled as such. Considered the hardiest member of the genus. Species is an important component of natural ecosystem in China and also utilized as a shade tree. Utilized as a rootstock for walnuts because of the high resistance to *Phytophthora* species. 'Fern Leaf' may belong here. See under *P. xrehderiana*. A "witches'-broom" associated with a Phytoplasma was reported in *Plant Disease* 89:529, 2005. China. Introduced about 1860. Zone (5)6 to 8.

*Pterocarya stenoptera****Pteroceltis tatarinowii*** Maxim. — Tartar Wingceltis

(tēr-ō-sel'tis ta-tār-i-nō'ē-ī)

FAMILY: Ulmaceae

LEAVES: Alternate, simple, ovate to ovate-oblong, 2 to 4" long, 3/4 to 2" wide, acuminate, broad cuneate, 3-nerved, irregularly and sharply serrate, upper medium to dark green, scabrous, lower with tufts of hairs in axils; petiole—1/4 to 1/3" long.

Pteroceltis tatarinowii is a handsome 30 to 45' high and wide tree with medium to dark green foliage. Usually smaller under cultivation and somewhat American Elm-like in outline. Tolerates the heat and drought of Zone 7. Fall color was respectable yellow-green in early November. Greenish yellow flowers on naked stems in early March in Zone 7. The species is closely allied to *Celtis* but differs in the winged, 1/2 to 3/4" wide fruits. The gray-brown bark exfoliates in scales/strips/patches and is quite handsome. The only trees I have observed grew at the Morris and JC Raulston Arboreta. For the plant collector this is a treasure to be unearthed. Have attempted to root late June softwoods with little (6%) success. Northern and Central China. Introduced 1894. Zone 5 to 7. Freezes back regularly at the Morton Arboretum.

Pterostyrax hispida Sieb. & Zucc. — Fragrant Epaulettetree

(tēr-ō-stī'raks hiss'pi-da)

FAMILY: Styracaceae

LEAVES: Alternate, simple, oblong to oblong-ovate, 3 to 7 1/2" long, 1 1/2 to 4" wide, acute or short-acuminate, rounded or cuneate at base, minutely denticulate, bright green and glabrous above, sparingly pubescent beneath at least on veins; petiole—1/2 to 1 1/2" long.

BUDS: Terminal elongated, hairy, and naked, 1/2" long, yellowish brown, sits at oblique angle to leaf scar; one or two smaller, ovoid, 2-scaled, brown, 1/4" long buds subtending terminal.

STEM: Quickly shedding-stringy gray bark, rounded, rather slender with distinct fetid odor when bruised; pith—off-white, continuous.

SIZE: 20 to 30' tall with a similar or greater spread although can grow to 45'.

HARDINESS: Zone 4 to 8, has survived -22°F; best in Zone 5.

HABIT: A round-headed, small tree that develops an open crown, and slender, spreading branches.

RATE: Medium, 12 to 14' in about 8 years.

TEXTURE: Medium-coarse in leaf; medium-coarse in winter.

LEAF COLOR: Bright green above, silvery green beneath in summer; yellow-green in fall and not effective; foliage is quite handsome and free of pest problems.

FLOWERS: White, perfect, fragrant, borne in large, 5 to 10" long, 2 to 3" wide, pendulous pubescent panicles which terminate short, lateral branches, May–June after the leaves have matured, trees start to flower when 8 to 10' high, corolla 5-lobed, divided almost to base.

FRUIT: A 1/2" long, cylindric, 10-ribbed, densely bristly, dry drupe.

CULTURE: Transplant balled-and-burlapped or from a container into moist, well-drained, preferably acid soil; full sun, have seen respectable plants in partial shade; in northern areas protect from strong winds and extremes of temperature; prune in winter; prefers hot, sunny conditions if good flowering is to occur.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Quite difficult to locate in commerce, but it does have possibilities for the small residential landscape; the flowers are extremely handsome and develop when a limited number of plants are offering color; makes a rather handsome and unusual tree; it is hardier than properly credited.

PROPAGATION: Seeds may germinate when directly sown but 3 months at 40°F is recommended to ensure more uniform germination. Softwood cuttings root easily and I have had 80 to 100% success with August cuttings treated with 3,000 to 8,000 ppm IBA-quick dip; the root systems were profuse and would serve as a model for any cutting one would ever hope to root.

NATIVE HABITAT: Japan, China. Introduced 1875.

RELATED SPECIES:

Pterostyrax corymbosa Sieb. & Zucc., (tēr-ō-stī'raks kōr-im-bō'sa), Little Epaulettetree, is distinguished from the above by the 1/2" long, 3/8" wide, 5-winged, ovoid fruits that are covered by a close down. Leaves are 2 to 4 1/2" long, 1 1/2 to 2 1/2" wide, serrulate with bristly teeth. Leaf thicker, fleshier, more substantial, *Hydrangea macrophylla*-like, with serrations pointing out from margin. Flowers, white, fragrant, occur in 3 to 6" long, corymbose panicles in June. As I observed the two species there is not much ornamental difference. This species tends to be more shrub-like. This species also roots readily from softwood cuttings. A rather tricky plant to identify in leaf; looks like nothing else, but then what is it . . . ? In summer of 2006 walked Smith College Campus and the Director, Dr. Mike Marcotrigiano, pointed me to this unidentified small tree/shrub. I pondered, said *P. corymbosa*; Mike said "what?" Kind of this plant's plight . . . operates under the garden radar. Japan, China. Introduced 1850. Zone 5 to 7.

Punica granatum L. — Pomegranate

(pū'ni-ka gra-nā'tum)

FAMILY: Punicaceae

LEAVES: Alternate, opposite, or whorled depending on growth rate of shoot, oval-lanceolate, 1 to 3" long, 1/3 to 1" wide, entire, glabrous, lustrous dark green; petiole—short.

STEM: Angled, light brown, glabrous.

SIZE: 12 to 20' high, spread equal to or less than height.

HARDINESS: Zone (7)8 to 10.

HABIT: Shrub or small tree of upright-oval to rounded outline; usually shrub-like in South.

RATE: Medium.

TEXTURE: Medium, perhaps almost fine.

LEAF COLOR: Lustrous dark green in summer, yellow-green to yellow fall color; leaves late to emerge in spring, also hold late in fall, tender spring foliage may be killed by late freeze.

FLOWERS: Perfect, self-fruitful, 5- to 7-petaled, petals crumpled; calyx with 5 to 7 lobes and a funnel-shaped base to which the numerous stamens are attached; effect is similar to a carnation; red in type, orange-red, pink, white, yellow or variegated in the cultivars; each flower an inch or more across, borne singly or up to 5 at end of branches, May, June–July, usually starts to flower in late May–early June on the Georgia campus and may continue into fall, quite handsome; tubular portion of flower is fleshy.

FRUIT: A yellow, maturing to red (yellowish red), brown-yellow, purple-red, 2 to 3 1/2"(5") diameter, globose, edible berry with a thick leathery rind crowned by the persistent calyx; central pulpy mass formed by the fleshy outer seed coats; ripens in September–October; fruits can be stored for long period, like apple, best to maintain them at 32 to 41°F.

CULTURE: Easily transplanted; tolerates extremes of soil from sand to clay providing they are well-drained; pH adaptable; sun or partial shade (reduced flowering in shade); grows best in fertile, moist, well-drained soils; probably best to prune before flowering since it flowers on new growth.

DISEASES AND INSECTS: None serious in typical garden situations; *Alternaria* fruit rot was reported in Greece with yield losses of 40 to 50%, fruit borers, fungal tung dieback, dry rot are mentioned.

LANDSCAPE VALUE: Truly a handsome shrub in flower; for some reason (cold hardiness) used sparingly in Piedmont area (Zone 7) of Georgia; good plant for shrub border, grouping, or perhaps screening; should not be used for hedges; really brightens a landscape in May–June and later; makes a fine container or tub plant, would be great on a patio during the summer months; flowers prolifically on Georgia campus; successfully used 'Nana' on the Georgia campus where in groupings it is quite handsome; success in the Dirr garden with this and other cultivars has been nil for dieback almost always occurred; in the March freeze of 1996, the plants were killed to ground level but resprouted; at Byron, GA, the USDA facility has a large collection of fruiting types, all orange-red flowered that are easily 10 to 15' high; low chill requirement, 150 to 200 hours, means plants can be grown successfully in Zone 9(10).

CULTIVARS: Several of the following may be found in commerce if one is tuned to treasure hunting. Numerous fruit-producing cultivars are offered by specialty nurseries. Louisiana Nursery, Opelousas, LA, 70570 offered the best selection.

'Alba Plena' ('Multiplex')—Double, creamy white or yellowish petals, waxy yellow calyx, new leaves bright green, 6 to 10' high.

'Albescens'—White flowers.

'Chico'—Compact form with more refined branches, glossy leaves and double, bright orange-red flowers over the summer.

'Cloud'—Bright pink, medium- to large-sized fruit.

'Cranberry'—Red fruit, abundantly produced.

'Elf'—Dwarf type to 5' with medium-sized, yellow-green fruit.

Favorite™—Abundant bright orange flowers; medium size, dark orange fruit; considered hardy to 10°F; Russian cultivar.

'Flavescens'—Yellow flowers, single, have seen it listed as double flowering.

'Granada' (PP 2,618)—Probably the hardiest flowering and fruiting clone; red flowers, red fruit with red flesh.

'Haku-Botan'—Frilly white, fully double flowers; cream-white fruit; smaller growing.

'Legrellei' ('Lagrelleae', 'California Sunset')—Double flowers with petals salmon-pink, variegated white (also described as red, striped yellowish white); apparently an unstable mutant from the double red, to which it reverts; has produced a branch sport with double white flowers; introduced before 1858 by Mme. Legrelle d'Hanis who obtained it from a friend, Mme. Parmentier, in Illinois.

var. *nana* (L.) Pers. ('Nana')—Red-orange, single flowers; smaller linear-lanceolate to linear leaves; smaller flowers and 1 to 2" wide, orange-red fruit; may only grow 18" high but 3 to 4'(6') can be realized; apparently several (perhaps many) forms of this in cultivation; cultivated in 1723 in Kent, England; will come true when grown from seeds; makes a good glasshouse plant and will flower and fruit inside; has been described as hardier than the species; has flowered in October on Georgia campus and held leaves into mid-November, some tip dieback after exposure to 0°F; have also witnessed plants killed to ground but resprouting; collected seeds in January, 2007, from a dwarf form at the Atlanta Botanical Garden with four seedlings resulting; all flowered within 6 to 8 months of sowing; one with eggplant-purple fruits, another continuous flowering; all with genetic dwarf foliage and habit; seedlings have been raised from these, all showing dwarf traits; further, the dwarf selections are being crossed with other flower color selections; this work is part of www.plantintroductions.com's new adventure.

'Nejikan'—Appears consistently cold hardy at the Raulston; orange-red flowers; medium-sized shrub; have not seen listed in everyday literature; certainly a doer for the past 8 years that I observed performance.

'Nochi Shibori'—Fully double, dark orange-red flowers; introduced by Brookside Gardens, Wheaton, MD; flowering March 19, 2005 at H.P. Leu Gardens, Orlando.

'Pleniflora' ('Plena')—Double, scarlet flowers, no fruit; 8 to 12' high.

'Scarlet Devil'—Compact, 4 to 6'; large, single, scarlet flowers; small, deep yellow, rounded fruits.

'Sochi Dwarf'—Crimson-red flowers from summer to fall; small red fruits; small, compact shrub, 3' by 3'; from southern Russia.

'Toyosho'—Double, light apricot to peach flowers.

'Wonderful'—A good fruit producer, burnished red fruit, juicy, wine-flavored; red-orange flowers; 8 to 12' high, fountain-like habit, vigorous grower.

PROPAGATION: Seeds germinate readily but progeny are extremely variable; this would be a good species to work with as far as flower color improvements and compactness. Germination results at PII showed 30 days stratification hastened and unified the process; 60 days may prove optimum. Softwood cuttings root readily; I have had good success with cuttings taken as late as September. The literature searches turned up numerous rooting studies, particularly prevalent in the Indian horticulture literature, 5,000 ppm IBA was an effective concentration for rooting basal and sub-apical cuttings. Also numerous tissue culture research papers. Utilized hardwood cuttings with good success.

ADDITIONAL NOTES: An "old" plant. Grown for its fruits in southern Europe, northern Africa east to India from remote antiquity. Needs sunny situation and a long, warm growing season if fruits are to ripen. Have seen it fruit heavily in Madison, GA. Is used abundantly at Williamsburg in the Governor's Palace Garden where it is planted with figs and espaliered pears. Fruit was apparently a delicacy for the landed gentry. Pomegranate now has a second wind and all manner of products because of antioxidant properties, particularly juices, adorn grocers and specialty shops. Relatively pricey. This may be the next notable home garden fruit in Zones 8 to 10. Zone 7 is acceptable for culture but a sneaky cold winter can wreak havoc.

NATIVE HABITAT: Lost to antiquity as far as origin; supposedly eastern Mediterranean to Himalaya. Cultivated since time immemorial.

Pyracantha coccinea M. Roem. — Scarlet Firethorn

(pī-ra-kan'tha kok-sin'ē-a)

FAMILY: Rosaceae

LEAVES: Alternate, simple, evergreen, narrow-elliptic to lanceolate or oblanceolate, rarely ovate-oblong, 1 to 2 1/2" long on long shoots, 1/2 to 1 1/2" long on flowering ones, range from 1/4 to 3/4" wide, acute, rarely obtusish, cuneate, closely crenulate-serrulate, lustrous dark green, slightly pubescent beneath at first; petiole—1/3" long, downy.

STEM: Woolly at first, becoming glossy brown with spines 1/2 to 3/4" long.

SIZE: 6 to 18' in height with an equal spread; this shrub can get out of hand and considerable pruning is necessary to keep it in bounds.

HARDINESS: Zone 6 to 9, Zone 5 if a hardy cultivar is used, the hardiest types will probably be killed at around -20°F.

HABIT: Semi-evergreen to evergreen shrub with stiff, thorny branches and an open habit if left unpruned; can become wild and woolly unless pruned properly throughout its lifespan.

RATE: Medium to fast.

TEXTURE: Medium throughout the seasons.

LEAF COLOR: Lustrous dark green in summer becoming brownish in winter in unprotected areas; if sited well, will maintain considerable green foliage.

FLOWERS: Perfect, whitish, 1/3" across, late April in Athens, late May–early June in Urbana, IL, borne in 1 to 2" diameter, 2 to 3" long, compound corymbs on spurs along the stem of last year's growth; quite showy in flower as the inflorescences literally shroud the plants; malodorous, subdued odor but still like a hawthorn.

FRUIT: Berry-like, rounded pome, 1/4" diameter, orange-red, ripening in September and persisting into winter; often spectacular.

CULTURE: Move as a container plant in spring into well-drained soil; does quite well where soil is dry in summer; full sun for best fruiting although will do well in partial shade; pH 5.5 to 7.5; pruning can be accomplished anytime; very difficult to transplant and once established should be left in that area; makes a good plant for container production.

DISEASES AND INSECTS: Fireblight can be serious, scab affects the fruits turning them a dark sooty color, *Phytophthora syringae* caused fruit rot, twig blight, leaf blight, root rot, aphid, leaf crumpler, lace bug, and scales.

LANDSCAPE VALUE: Often used as an informal hedge or barrier plant, good for espaliers on walls, trellises and the like; fruit is the outstanding attribute; hardiness is a problem and selected cultivars must be used; The Ohio State University campus utilized large numbers of *Pyracantha* that were spectacular in the fall; somewhat out-of-favor because of wild, sprawling habit, and thorns (may cause a reaction), smelly flowers, and disease susceptibility; there are many easier-to-culture shrubs but few with the fruiting abundance of firethorns.

CULTIVARS: U.S. National Arboretum publication, *A Checklist of Pyracantha Cultivars* (1995), Contribution Number 8, is a wonderful guide. The number is colossal.

'Aurea'—Form with yellow fruits.

'Baker's Red'—Listed by Greenbriar Farms as their best red "berried" pyracantha for abundance of bright red fruit and cold hardiness.

'Chadwickii'—(Zone 5) Hardy form and a prolific fruiter, fruits are orange-red; 6' high, spreading habit; one nursery noted it was hardier than 'Lalandei'; named after Dr. L.C. Chadwick, one of my mentors at Ohio State.

'Forest Hills'—Compact habit, 5 to 6' high and wide, orange-red fruits; Hines introduction.

'Government Red'—Red fruits, heavily produced; 6 to 10'; listed hardy to -5°F; I am not sure about nomenclatural integrity but then the name fits.

'Kasan'—(Zone 5) Orange-red fruits; originated in Russia, one of the hardier forms; quite scab susceptible; spreading growth habit, 10'.

'Lalandei'—(Zone 5) Probably the most widely grown and one of the hardiest, with orange-red fruits; originated about 1874; vigorous to 10 or 15'; scab susceptible.

'Lalandei Monrovia'—Orange-red fruits and slightly less hardy than 'Lalandei', also saw a report that notes significantly less hardy; also quite scab susceptible.

'Red Column'—Upright growth habit and bright red fruits; listed as Zone 5 to 6 by Angelica Nursery.

'Royal'—Hardy, upright-branched, orange-fruited form.

'Runyanii'—Another orange-fruited form; highly scab and fireblight susceptible.

'Thornless'—Red-fruited, thornless form supposedly as hardy as 'Lalandei'; highly susceptible to scab and fireblight.

'Wyattii'—Orange-red fruits prolifically produced; hardy to Zone 5; supposedly more cold hardy than 'Lalandei'; 9 to 12' high; tolerant of poor soil; highly susceptible to scab and fireblight.

OTHER CULTIVARS OF DIFFERENT PARENTAGE: The above were primarily derived from *Pyracantha coccinea* but the following come from different parentage. Dr. Donald Egolf, U.S. National Arboretum, and Dr. Elwin Orton, Rutgers University, have hybridized a number of fine cultivars many of which are included here.

'Apache'—A semi-evergreen to evergreen compact shrub with 1/3" diameter, bright red fruits that ripen in September and persist until December and are not readily devoured by birds; resistant to pyracantha scab and fireblight; leaves are glossy dark green, grew 4 1/2 to 5' high and 6' wide after 14 years; a U.S. National Arboretum introduction; see *HortScience* 22:173–174 (1987); should be cold hardy in Zone 5/6.

'Cherri Berri' (*P. crenatoserrata* (Hance) Rehd.) (PP 3,887)—Large, 3/8" diameter, cherry red fruits which persist into winter; large, lustrous dark green leaves; 10' by 8'; Zone 6 but I doubt this designation, probably less cold hardy.

'Dart's Red' ('Interrada')—Medium-size shrub with large red fruits; resistant to scab and fireblight.

'Fiery Cascade'—An upright grower to 8' high and 9' wide; small glossy dark green leaves; abundant small red fruit, first orange in September, red in October and persisting; good disease resistance; hardy to -10°F; Dr. Orton, Rutgers, introduced this clone.

Gnome® ('Gnozam')—Obviously I had the parentage wrong in the third edition for a number of reasons but John Sabuco straightened out the problem. Gnome® is a seedling of *P. coccinea* 'Lalandei' × 'Aurea'?

The patent tag read *P. angustifolia* (Franch.) Schneid. Gnome® and in the disease update Oregon State listed it as *P. atalantioides* (Hance) Stapf. Got it! Medium-sized shrub of compact, densely branched growth and somewhat spreading nature; 1/4 to 3/8" diameter, orange fruits; quite hardy and successful in Zone 5; highly susceptible to scab on leaves and fruits; 6' by 8'; introduced by Lake County Nursery.

- 'Gold Rush'—Yellow-fruited hybrid of *P. angustifolia* × *P. fortuneana* selected by Washington Park Arboretum, University of Washington and registered in 1976 after 20 years of testing; described as an intricately branched shrub to 10' high; persistent leaves and dense clusters of depressed-globular; orange-yellow, nearly 1/2" diameter fruits that are so numerous the branches arch to the ground; resistant to scab and hardy to Zone 7.
- 'Golden Charmer' (*P. crenulata* (D. Don) M. Roem. var. *rogersiana* A.B. Jacks. × *P. coccinea*)—Orange-yellow fruits; good lustrous dark green foliage; scab resistant; bred in Germany.
- 'Graberi' (*P. fortuneana*)—Large, red fruits persisting into winter, 10 to 12' by 8 to 10', vigorous, upright branching; Zone 7.
- 'Harlequin'—Pinkish white variegated new shoots settle down to a life of green and white in summer, turn pinkish in cold weather; 6' high and wide shrub; not as vigorous as the species; fruits are orange-red; as pyracanthas go this is at the bottom of the heap.
- 'Lowboy'—Vigorous, spreading, low-growing form; rich green foliage; orange fruit; extremely susceptible to scab; 2 to 3' high and wider at maturity.
- 'Mohave' (*P. koidzumii* × *P. coccinea* 'Wyattii')—Heavy flowers and huge masses of bright orange-red berries on a medium-sized, densely branched, upright variety, grows 6 to 10' (9 to 12' high); based on tests in Illinois it is not hardy much below 0 to -5°F; quite resistant to scab and fireblight, recent reference (2002) noted high scab susceptibility; lustrous dark green foliage; fruits exceptionally resistant to bird feeding; 8-year-old plant listed as 13 1/2' by 16'.
- 'Mohave Silver'—Leaves gray-green with thin white margin; red fruits; listed in Hillier 2002, but fruit color does not jibe with that of true 'Mohave'.
- 'Navaho' (*P. angustifolia* × *P. 'Watereri'*)—Low-growing, 6' high and 7 1/2' wide, densely branched, mounded; rich orange-red fruits; resistant to scab and highly tolerant to fireblight.
- 'Orange Charmer' (*P. crenulata* var. *rogersiana* × *P. coccinea*)—Orange-red, 3/8" diameter fruits that color in September; scab resistant; bred in Germany.
- 'Orange Glow' (*P. crenatoserrata* (Hance) Rehd. × *P. coccinea*)—A popular form in England which has proven quite hardy; quite free-flowering with masses of orange-red, 3/8" diameter fruits which persist into winter; used frequently as an espalier on walls, 10' or more; scab resistant.
- 'Pauciflora'—Dense branching, low rounded form with small leaves and light crops of small, orange fruits, 4' by 4'; this may be a rename.
- 'Pueblo'—A semi-evergreen to evergreen, dark green leaved, 6 to 7' high, 12' wide shrub (after 16 years) with 1/3 to 1/2" diameter, depressed globose orange-red persistent fruit; resistant to fireblight and scab; vigorous-growing and heavy fruit producer; hardy to Zone 7; see *HortScience* 22:510–511 (1987).
- 'Red Column'—Broad upright form, 8 to 10' by 8 to 10'; clean foliage; bright red fruits.
- 'Red Cushion'—Compact habit, tight-branching, 3 to 4' high; dark red fruits; fireblight resistant.
- 'Red Elf'—Dwarf compact mounding habit; dark green foliage; bright red persistent fruits; low susceptibility to fireblight; Zone 7; Monrovia introduction.
- 'Ruby Mound'—Low mounding type with bright red fruits; Zone 7; Monrovia introduction.
- 'Rutgers'—A good, glossy dark green leaved form with abundant orange-red fruits and a spreading, sprawling growth habit, may reach 3' high and 9' wide; good disease resistance; roots easily from cuttings; shows good hardiness, much harder than 'Mohave' and 'Navaho'; introduced by Dr. Elwin Orton, Rutgers University.
- Saphyr Jaune™ ('Cadaune'), Saphyr Orange™ ('Cadange') and Saphyr Rouge™ ('Cadrou')—All at one time in the Raulston Arboretum collection: the first with yellow fruits; the second, deep orange fruits, scab and canker resistance; the third, rich red fruits, scab and fireblight resistance; Saphyr Panache™ ('Cadvar') is also listed.
- 'Shawnee'—An F2 seedling of *Pyracantha* 'San Jose', which is a spontaneous hybrid of *P. koidzumii* and *P. fortuneana*; clear yellow to light orange fruit, semi-persistent foliage; resistance to fire blight and scab; original plant was 9' by 10'.
- Silver Lining™ ('Cadvar', PP 15,517)—Emerald-green leaves with stable silver variegation that gradually ages to green, shows no necrosis in sun, fall foliage is eye-catching bronze and pink, in warmer climates will remain evergreen; orange red fruits; refined growth habit and nearly thornless; 3' by 3'; listed Zone 6 to 10; have seen in mid December and foliage is rose-tinged.
- 'Soleil d'Or'—Another European garden form with golden yellow fruits; 8 to 10' high.
- 'Teton' ('Orange Glow' × *P. crenulata* var. *rogersiana* 'Flava')—Quite unusual for its upright growth habit and yellow-orange fruits; growth habit and fruit color are somewhat affected by where it is grown; in South fruits are yellow-orange and habit is upright-spreading but nowhere as upright as shown and

described in original cultivar release (see *HortScience* 13(4): 483–484); it is a strong grower and may become 16' high and 9' wide; resistant to scab and fireblight; reasonably hardy.

'Thornless'—No thorns; spreading habit, 8 to 12' by 8 to 12'; large, clean foliage; black stems; bright orange fruit; have only been listed by Klyn Nurseries, Inc.

'Wonderberry'—Orange-red fruits; 10' by 10', good espalier form; Zone 7.

Yukon Belle™ ('Monon') (*P. angustifolia*)—Monrovia lists this form as the hardiest orange-berried form; medium-sized shrub with semi-evergreen tendencies, probably 6 to 10' high and wide; listed as Zone 4 but I doubt it.

PROPAGATION: Seed should be stratified for 90 days at 41°F. Softwood cuttings root readily under mist; treatment with 1,000 to 3,000 ppm IBA is recommended to hasten rooting.

ADDITIONAL NOTES: *Pyracanthas* make attractive fruiting shrubs but can become ratty with age. The disease ratings come from *Ornamentals Northwest*, December–January, 1977–78. A number of other cultivars were not included here because of their relative scarcity in commerce but are described in the publication. Other cultivars in European commerce listed in RHS Plant Finder 2007–2008. Counted approximately 10 yellow-fruited cultivars. *Pyracantha*, in general, has lost its landscape pizzazz and, though commercially available, newer shrub introductions have reduced the plant's clout. In the South, the new *Loropetalum chinense* var. *rubrum* cultivars have competed favorably. Might mention that *pyracantha* spines can induce reactions in humans. Wear leather gloves when pruning and handling.

NATIVE HABITAT: Italy to Caucasus. Introduced 1629.

Pyracantha koidzumii (Hayata) Rehd. — Formosa Firethorn

(pī-ra-kan'tha koyd-zūm'ē-ī)

LEAVES: Alternate, simple, evergreen to semi-evergreen, oblanceolate, widest above the middle, 1 to 3" long, 1/2 to 3/4" wide, entire, or slightly serrate toward apex, apex often emarginate, lustrous dark green; easily separated from *P. coccinea* by the essentially entire leaf and emarginate apex; in clusters on old wood.

SIZE: 8 to 12'(20') high, 8 to 12'(20') wide.

HARDINESS: Zone 8 to 10; this species is not reliably hardy in Zone 7; severely injured and in exposed locations killed to ground during 1981–82 winter in Athens when temperatures dropped to 0°F, same occurrence in 1983–84 at –3°F, some plants killed, others developed new shoots from base.

HABIT: Large multi-stemmed, stiff, upright-branched shrub that becomes unkempt with time unless properly pruned; like *P. coccinea* this is a rank grower and rather unruly.

RATE: Fast.

TEXTURE: Medium.

LEAF COLOR: May start leafing out as early as late February in Athens; lustrous dark green; foliage may discolor in colder areas of South.

FLOWERS: Perfect, 5-petaled, malodorous, white, 1/4" diameter, produced in small corymbose racemes in mid-April–early May (Athens); an entire plant in flower is quite attractive.

FRUIT: A globose, 1/4" diameter, red pome that matures (colors) in September–October and persists through the ensuing winter; the entire shrub is a great mass of red; several plants on the Georgia campus are isolated specimens and they stand out like a sore thumb; birds apparently leave these until they are desperately hungry.

CULTURE: Transplant from a container; *Pyracantha* is inherently impossible to move from the field; prefers well-drained soil and full sun; responds vigorously to good growing conditions; an excellent choice for hot, dry areas; plants on the Georgia campus have survived numerous droughts and fruited heavily; prune selectively; there is no one best time to remove branches.

DISEASES AND INSECTS: Fireblight, lacebug, scab (affects fruit), mites in extremely dry situations, scale and leaf rollers.

LANDSCAPE VALUE: Excellent for fruit effect and widely used for every conceivable landscape purpose; single specimen, foundation plantings, hedges (a mistake), screens, masses, espaliers; requires a great amount of maintenance to keep it looking nice; where space permits it is worth using; the most widely used species in the Southeast.

CULTIVARS:

'Low-Dense' ('Lowdense')—Mounded habit of growth to 6'; large orange-red fruits may be masked by foliage; new growth light green; texture fine, severely injured or killed at 11°F during 1983–84 winter, true also for 'Red Elf' and 'Ruby Mound'.

'Rosedale'—Branches arching; large bright red fruit; considered fireblight resistant.

'San Jose'—Wide-spreading form; highly scab resistant.

'Santa Anna'—Dark red fruits; shiny large lustrous green foliage; 10' by 10'; Zone 7.

'Santa Cruz'—Prostrate form with dark green leaves and red fruits; highly scab resistant; 2 1/2 to 3' by 5 to 6'; Zone 7.

'Victory'—Vigorous form, upright arching growth habit, with dark red fruit; fruits among the last to color but are retained for many months; Zone 7; 10' or more; good scab resistance.

'Walderi Prostrata'—Prostrate growth habit; 4'; large red fruits.

'Watereri'—Parentage is suspect but probably *P. atalantioides* × *P. crenulata* var. *rogersiana*; vigorous, dense shrub up to 8' high and wide; dark red fruits on nearly thornless stems; leaves relatively small, 3/4 to 1 1/4" long, 1/4 to 1/2" wide, occasionally 2 1/2" long.

'Waterer's Orange'—Vigorous shrub with orange-yellow fruits.

PROPAGATION: Cuttings root readily especially from July to October when treated with 3,000 ppm IBA-quick dip.

ADDITIONAL NOTES: Many cultivars available; disease susceptibilities are based on evaluations made in the Pacific Northwest.

NATIVE HABITAT: Taiwan.

Pyrus calleryana Decne. 'Bradford' Bradford Callery Pear. This discussion is concerned with the cultivar 'Bradford' and not the species.

(pī'rus kal-er-ē-ā'na)

FAMILY: Rosaceae

LEAVES: Alternate, simple, broad-ovate to ovate, 1 1/2 to 3" long, about as wide, rarely elliptic-ovate, short acuminate, rounded, broad-cuneate, subcordate or truncate at base, crenate, usually quite glabrous, leathery, lustrous dark green; petiole—1 to 1 1/2" long.

BUDS: Large, terminal and laterals of approximately same size, ovoid, elongated, 1/2" long, intensely woolly, dirty gray to gray-brown.

STEM: Stout, brownish sometimes exhibiting ridges running from base of leaf scar, generally white woolly pubescent, especially below terminal, gradually changing to smooth, glossy brown at maturity, thornless.

SIZE: 30 to 50' in height with a 20 to 35' spread; 20-year-old trees were 50' high and 40' wide.

HARDINESS: Zone 5 to 8(9).

HABIT: Moderately conical (pyramidal) in youth, and broadening with time, densely branched and foliaged making it one of the great widget trees in American commerce.

- RATE:** Fast, 12 to 15' over an 8 to 10 year period; a 12-year-old tree at the Secret Arboretum was 24' high, 22' wide, and 7" in diameter.
- TEXTURE:** Medium in leaf, medium in winter.
- BARK:** Lustrous brown in youth, lightly ridged-and-furrowed and grayish brown at maturity, often developing horizontal checks with age, creating a somewhat blocky appearance.
- LEAF COLOR:** Outstanding glossy dark green in summer changing to glossy scarlet and purple shades in fall; very spectacular in fall color but variable; I have observed a great number of Bradford Pears in fall coloration and some were spectacular reddish purple, others yellow to red reminding of a persimmon orange; the leaves hold late and in northern areas color may not develop properly depending on the earliness of cold weather; in the South fall color is often an excellent glistening yellow to red and peaks in mid to late November, with some leaves colorful into December; leaves literally frozen on trees at 3,600' elevation; colorful (fall) at 2,200', December 2000, Rabun County, GA.
- FLOWERS:** White, 3/8 to 3/4" across, borne in 3" diameter corymbs before or with the leaves, malodorous, in full flower in early to mid-March in Athens, GA, and late April–early May in Urbana, IL, the tree looks like a white cloud in full flower; beautiful flowering tree.
- FRUIT:** Small rounded pome, 1/2" or less across, russet-dotted, hidden by the foliage; not ornamentally effective; may be present in great quantities; fruits can be eliminated by 1,000 ppm Ethephon sprayed at full bloom, 95.3% of fruits removed in California study, see *California Agriculture* 48:21–24 (1994).
- CULTURE:** Easy to transplant container-grown (anytime) or balled-and-burlapped if moved in late winter or early spring; some nurserymen will not move them in leaf, very adaptable to many different soils; tolerates dryness, pollution, and should be sited in full sun; prune in winter or early spring.
- DISEASES AND INSECTS:** Variable resistance to fireblight which is so troublesome to the Common Pear, *Pyrus communis*; basically free of pests although I have seen tip dieback from fireblight in the South; many loose statements on fireblight susceptibility with one of the best documented studies (Alabama) in *J. Arboriculture* 17:257–260 (1991); in their study 'Aristocrat' and 'Autumn Blaze' were highly susceptible with 'Bradford' the least.
- LANDSCAPE VALUE:** In the second (1977) edition, I commented that I hoped to see more Bradfords; little did I realize that this cultivar would literally inhabit almost every city and town to some degree or another; the tree has reached epidemic proportions and is over-planted similar to Green Ash, Silver Maple and Siberian Elm; 'Bradford' is beautiful but not a panacea for urban planting; problems have surfaced that should give reason to temper enthusiasm for the cultivar; incompatibility and severe splitting are occurring on older trees; Bradford tends to develop rather tight crotches and I have seen trees that were literally split in half; new cultivars have been introduced and several show promise; 'Bradford' is still popular but its limitations have been recognized by many knowledgeable plantmen and nurserymen; unfortunately, the buying public has not yet caught up; for short term use perhaps 10 to 15 years, 20 with luck, the tree is magnificent; the plant will literally fall apart because of the development of many branches around a common length of the trunk, plants manifest the problem by losing the distinct pyramidal shape and eventually becoming wide fan-shaped; plants have literally split in half before even reaching the fan shape; a move toward better pruning in the nursery has been advocated but economically and practically this has not worked out; genetically the tree is programmed to grow the way it does; if liabilities are understood then the plant is acceptable for use. 'Bradford' was the first selection of *P. calleryana* and was selected at the USDA Plant Introduction Station, Glenn Dale, MD from seedlings of Chinese seed, named in 1963, at that time the original tree was 44-years-old, 50' high and 30' wide; I suggest that the reader refer to Dirr, "What do we know about cultivars?" *American Nurseryman* 154(6) (1981).
- The above can be largely dittoed for this edition. Many nurserymen have stopped growing the tree and switched to 'Chanticleer'; which, to date, is a longer-lived, more stable selection. One thing is absolute, when a tree like 'Bradford' is known and accepted by the buying public; it is difficult to remove it from their consciousness. 'Bradford' will be a part of the North American landscape well into the 21st century.
- Gerhold and McElroy, *J. Arboriculture* 20:259–261 (1994), evaluated eight *P. calleryana* cultivars, 2 of each cultivar in 10 communities in Pennsylvania; best were 'Aristocrat', 'Chanticleer', and 'Redspire'; 'Whitehouse' was the worst.
- Bonnie and I comment about the overuse of the cultivar, particularly where native trees provide the architectural structure of a garden, street or neighborhood. The "cookie-cutter" Bradfords, lining drives and streets, are difficult to digest, particularly because I realize their time is finite.
- My newest (2009) 'Bradford' rant concerns the extreme number of escaped seedlings along highways, interchanges, abandoned fields and any open area. From early to late March along I-85, Athens to Chapel Hill, pear seedlings own the landscape. I am not sure about invasive status but this species in the broadest sense concerns me. Stacy Kish's article in *NMPro*, 24(5) (2008), Ornamental pears offer new option: invasiveness, addresses this problem.

OTHER CULTIVARS:

Aristocrat[®] (PP 3,193)—Selection in 1969 by William T. Straw, Carlisle Nursery, Independence, KY; basically pyramidal to broad-pyramidal in outline, branches more horizontal and crotch angles wider, lustrous dark green leaves with a wavy edge and for that reason quite distinct from other *P. calleryana* selections; fall color is variable and ranges from yellow to red; trees I have seen were not as good as 'Bradford' although it is advertised as having better fall color; flowers are more sparsely borne but still quite attractive; tends to maintain a central leader and shows great vigor for 6-year-old trees may be 12' high, 10' wide with a 3" trunk diameter; 36' high and 16' wide after 15 years; thornless; shows about the same cold and heat tolerance as 'Bradford'; is more fireblight susceptible than 'Bradford'; fireblight in the Southeast during 1988 and 1989 was devastating on this cultivar, many growers refuse to plant another 'Aristocrat'; in the North I have not noticed the problem to the degree it has occurred in the South; used along Broad Street, one of the main thoroughfares into Athens, and has performed respectably in spite of the fireblight infestations, these trees (2007) are now embarrassingly disheveled; flowers later than 'Bradford' and structurally has held together over time; on March 10, 1991 I noted that 'Aristocrat' was still in bud while 'Bradford' was in full flower; older specimens at Bernheim and Mt. Airy Arboreta, and Arlington Memorial Gardens, Cincinnati attest to this; with time the central leader is lost and trees are 40 to 45' high by 20 to 25' wide; Capiello reported 'Aristocrat' hardy at Orono, ME while 'Bradford' was killed; Zone 4.

'Autumn Blaze' (PP 4,591)—An introduction by Dr. Westwood, Oregon State, for consistent, early, reddish purple fall color; it is also more cold hardy than 'Bradford'; supposedly with upright, pyramidal crown with lateral branches at about right angles to the central leader, trees I have seen have been more pyramidal-rounded; also will develop a few thorns, appears highly susceptible to fireblight; selected in 1969 at Oregon State, patented in 1980; definitely more rounded than 'Bradford' in habit; successful in Orono, ME; 30' by 25'; Zone 4.

Burgundy Snow[™]—Pyramidal habit, 35 to 40' by 25 to 30'; pure white flowers with burgundy center; 7/8" diameter, cinnamon fruit; rich green leaves; Zone 4; Lake County Nursery introduction.

'Cambridge'—Upright, narrow pyramidal, 40' by 15'; glossy green foliage turns orange in fall; selected in Indiana because of increased cold hardiness; displays excellent vigor and form, less brittle than other cultivars.

'Capital' ('Capitol')—Introduction from the U.S. National Arboretum that is more upright than 'Whitehouse' and theoretically can be substituted for Lombardy Poplar; its leaves turn coppery in fall; see *HortScience* 16(6):799–800 (1981); early reports indicated it was a good selection; leaves are a lustrous dark green, grew 32' high by 8' wide after 15 years, possibly a good choice for narrow restricted growing areas; evaluations (1988 and 1989) reported tremendous fireblight susceptibility, in fact, so great that nurserymen are removing it from the fields in southern nurseries; devastating fireblight in Oconee County, GA, May 2000 and 2007; this is about the worst for fireblight susceptibility and also one of the ugliest cultivars as it ages; branches are irregular in disposition, actually rather ugly . . . what can we expect from a government tree?

Chanticleer[®] ('Glen's Form', PP 2,489) (same as 'Select', 'Cleveland Select' and 'Stone Hill')—A fine upright-pyramidal form that is much narrower than 'Bradford'; it flowers heavily and fall color may be a good reddish purple; the times I have seen it in fall color it did not measure up to 'Bradford'; leaves turn more yellow, orange, apricot; the leaves are longer and more ovate (see drawing) than 'Bradford' and thinner in texture; thornless; a fine tree and probably a better choice where lateral space to spread is limited; interestingly 'Chanticleer' hardens off earlier than 'Bradford' and may be less susceptible to early freezes; will grow 35' high, 16' wide in 15 years; has shown good fireblight resistance; a 1965 Scanlon introduction, patented in 1965; I have always admired this cultivar and the passing years have not diminished the flame; in fact, it would be my first choice of the *P. calleryana* types; flowers later than 'Bradford', perhaps a week or more removed;

also, almost as cold hardy as 'Autumn Blaze'; does not maintain a central leader and multiple leaders are common but the tree does not spread like 'Bradford'; the oldest tree I remember resided on the Peter's Hill side of the Arnold Arboretum and was still tightly columnar-pyramidal when last observed in 1991; a 35' high tree at Hillier was just coming into flower on February 27, 1999, this tree had the tight conical habit and was in good condition.

'Chanticleer'

- Dancer™ ('Southworth', PP 7,033)—A selection of *P. betulifolia* Bunge, new leaves gray-green on long flexible petioles, shimmer in the slightest breeze; prolific white flowers before the leaves emerge in spring; small 3/8" diameter russet fruits; ovate growth habit, 30' high, 20' wide; introduced by Bill Wandell.
- 'Earlyred'—As I understand the introduction, a seedling of 'Bradford' with earlier developing red fall color and more compact habit, from the late, great Bob Simpson, Vincennes, IN who gave our garden world many great plants that have withstood the test of time, including: 'Winter King' hawthorn, 'Winter Red' Common Winterberry, Candymint Sargent Crabapple, ad infinitum; witnessed the plant at Bernheim Arboretum in early November 1997 among the other *P. calleryana* cultivars, 'Bradford' was in shambles, while this cultivar was densely branched and exhibited none of the fall-apart-at-the-seams traits of 'Bradford'; growers need to take a serious look at this clone as an alternative to 'Bradford'; slower growing than 'Bradford'.
- Edgewood® ('Edgedell', PP 10,151)—A hybrid between *P. calleryana* × *P. betulifolia* Bunge; round-headed, small tree, 30' by 25'; silvery green foliage turns reddish purple in the fall, emerging leaves with a purple tint; flowers white; Schmidt Nursery introduction; Zone 5; full flower March 8, 2006 at Milliken Arboretum; quite a handsome tree; habit has become more open than 'Bradford'; abundant, ovoid fruits May 20, 2007.
- var. *fauriei* ('Fauriei', *P. fauriei* C.K. Schneid.)—Often listed as a variety and by some authorities considered a species but because it is vegetatively propagated I will treat it as a cultivar; this is another tree that the literature said will be small (20') and round-headed; unfortunately, the plant did not read the book and we know it will grow 30 to 40' and develop a pleasing pyramidal outline; the ovate leaves are lustrous dark green and thin; it tends to fall color (yellow or red) earlier than 'Bradford' and drop the leaves earlier; tends to develop a nice crown even in youth; its crotch angles are wider than 'Bradford' and it makes a less stiff, formal appearance in the landscape; supposedly it shows good urban soil tolerance; the buds on this form are distinctly different than the other *P. calleryana* types for they are reddish brown and show only a minor amount of gray pubescence; thornless; a fine tree in Spring Grove was devastated by storm damage; grew 32' by 25' in 15 years; in Kansas, averaged 1'4" per year over an 8 year period; Martin Meyer, retired, University of Illinois, grew a population of *P. fauriei* and the seedlings were smaller in leaf, 1 to 2" long, the habit shrubby and smallish, the branches spiny, none equated with the 'Fauriei' that is described above; I suspect that a *P. calleryana* type was pinned with the 'Fauriei' name; true *P. fauriei* is inferior to true *P. calleryana* for ornamental purposes.
- Gladiator® ('Galzam')—Pyramidal with strong central leader, upright branching, 35 to 40' by 20 to 25'; white flowers; 7/8" diameter, tan fruit; glossy dark green leaves, burgundy-bronze in fall; Zone 4; Lake County Nursery introduction.
- Jack® ('Jaczam')—Compact, upright-oval, 15' by 10'; white flowers, 3/4" diameter, yellow-green fruit; dark green leaves, yellow in fall; good choice where space is limited; Zone 4; Lake County Nursery introduction.
- Jill™ ('Jilzam')—Rounded habit, 15' by 15'; olive-green leaves, smaller than those of Jack®; white flowers; 3/4" diameter fruit; Zone 4; Lake County Nursery introduction.
- Korean Sun™ ('Westwood') (*P. fauriei*)—Compact, rounded habit, 12' by 15'; fine-textured medium green foliage, red to red-purple fall color; white flowers; hardier than *P. calleryana*; Zone 4.
- New Bradford® ('Holmford')—Superior branching, broad oval to rounded; glossier leaf, glossy dark green, yellow to orange-red fall color; 35' by 30'; considered more disease resistant, hardier than Bradford; John Holmlund introduction.
- 'Princess'—I have only seen the tree on one occasion and it reminded of a 'Bradford', considered a rounded form of 'Bradford' but hardier, the original tree (25-years-old) was 28' high with an equal spread; fall color orange to red; a Scanlon introduction in 1976, found on a Cleveland, OH street.
- Pzazz™—A smaller form than 'Bradford' with attractive bright green leaves and distinctive ruffled leaf margins; better branch structure than 'Bradford' or 'Redspire'; 35' by 25'; Zone 5 to 7; probably a *P. betulifolia* selection; a Wandell introduction.
- 'Rancho'—Another Scanlon introduction with a columnar pyramidal form, fall color develops about 10 days earlier than 'Chanticleer', after 15 years averaged 32' high and 15' wide.
- 'Redspire' (PP 3,815)—A pyramidal form, 35' by 25' without the inherent stiffness of 'Bradford'; the ovate leaves are thick, shiny dark green and turn more yellow than red in fall; it colors ahead of

'Bradford'; and in my estimation makes a fine tree; thornless; slower growing and does not caliper as fast as 'Bradford'; unfortunately, quite susceptible to fire blight; originated as a seedling of 'Bradford'; ceases growth in early fall; patented in 1975 by Princeton Nursery.

Spring Show™ ('Wilcher 1')—Crown form similar to Aristocrat pear, wide crotch angles; glossy green summer foliage, purple to dark red in fall; 25' by 25'; noted in Holmlund 2008–2009 catalog.

'Stonehill' ('Stone Hill')—Apparently another name for 'Chanticleer', was informed by a Pennsylvania nurseryman that this is another rename.

'Trinity' ('Sylvania', PP 4,530)—Tightly rounded head; profuse single white flowers; glossy light green leaves, orange-red fall color; negligible fruit; 30' by 25 to 30'; introduced in early 70's by Handy Nursery, Oregon, not well-known but the few trees I observed were handsome; more cold hardy than most cultivars and survived –31°F in Northern Kentucky in early 1990s.

Valiant® ('Valzam', PP 8,050)—Upright, pyramidal, 20 to 25' by 15 to 20'; hunter-green leaves turn crimson-red in fall; white flowers; 1/4" diameter fruit; Zone 4; Lake County Nursery introduction.

'Whitehouse'—A U.S. National Arboretum introduction selected in 1969 from a population of 2,500 seedlings resulting from an open pollination of 'Bradford' and other *P. calleryana* seedlings; it develops a columnar-pyramidal form with a strong central leader and fine, profuse, upward arching branches, a tree may be 14' high and only 3 1/2' wide, 35' by 14' after 14 years; the leaves are glossy green, long pointed and narrower than 'Bradford'; fall color may range from red to reddish purple, colors earlier than other cultivars; in youth it is a faster grower than 'Bradford' because of the strong dominance of the central leader; thornless; see *HortScience* 12:591–592 (1977): flowers about 5 days later than 'Bradford'; leaf spot is terrible and disfigures leaves to the degree that trees are a liability; considerable hype has surrounded this tree and claims like "more urban tolerant and drought tolerant than 'Bradford'" have been made; unfortunately, this form is less than desirable and several southern nurserymen who started to grow the plant in the early 1980's have quit; along with 'Capital' two of the most miserable cultivars; government trees, like government cheese, may fall short.

Santamour and McArdle, *J. Arboriculture* 9(4):114–116 (1983) provide excellent background information on the species and cultivars. Also Haserodt and Sydnor, *J. Arboriculture* 4(6):160–163 (1983) profile the growth habits of 5 cultivars of *P. calleryana*.

PROPAGATION: Seeds of the species require cold (32 to 36°F) for 60 to 90 days. Seeds collected mid-January from trees at the Atlanta Botanical Garden germinated 7 days after planting. Apparently the seeds had received sufficient natural cold moist stratification while still in the fruit. Good paper on seed germination of 69 *Pyrus* crosses appeared in *Landscape Plant News* 3(2):13–14 (1992); in brief, germination was excellent for most crosses after cold-moist stratification for 90 days at 35°F. Much has been written about rooting cuttings and my graduate students and I have conducted considerable work. The best success I have seen was at Greenleaf Nursery, OK where the former propagator now President, Randy Davis took firm cuttings, treated them with 10,000 ppm IBA + 5,000 ppm NAA quick dip, bark: sand, mist and achieved 70% rooting, with quality root systems. Also Gilliam et al., *J. Environ. Hort.* 6:81–83 (1988), reported 1 or 2% IBA in aqueous or ethanolic KOH solutions, or 2% KIBA promoted greatest rooting of terminal cuttings.

ADDITIONAL NOTES: The urban tolerance of this group makes them first choice when the questions are asked . . . what goes along the street? . . . in the planter? . . . in the parking lot? Have noticed numerous escapees and *P. calleryana* seedlings are forming monocultures in some areas of the South. Interestingly, I have walked these escapees and to date have seen nothing that supersedes the current cultivars in foliage, also most are thorny.

Worthwhile pear cold hardiness data in *North American Plant Propagator* 3(2):14–15 (1991) that points to 'Bradford' and other pear problems in northern climes. The data are presented in tabular form.

Lowest temperature tested (°F) that did not result in severe injury of stem tissue of *Pyrus* taxa:

TAXA	DATE TESTED		
	10-22-90	11-14-90	01-14-91
'Aristocrat'	+ 6.8	–4.0	–32.8
'Autumn Blaze'	+ 6.8	–4.0	–29.2
'Bradford'	+24.8	+3.2	–14.8
'Capital'	+21.2	–7.6	–18.4
'Chanticleer'	+ 3.2	–7.6	–22.0
'Redspire'	+17.6	+3.2	–25.6
'Whitehouse'	+21.2	+3.2	–22.0
'Fauriei' (<i>P. fauriei</i>)	+14.0	–4.0	–25.6

Interestingly, 'Bradford' was consistently killed at the University of Minnesota Landscape Arboretum. Additional information in *J. Environ. Hort.* 12:227–230 (1994). In the latter study, the data conclusively showed 'Autumn Blaze' was the most cold hardy followed by 'Chanticleer' in Minnesota, but both were killed after exposure to -33°F . *Pyrus fauriei*, *P. salicifolia* 'Silver Frost', and *P. ussuriensis* also survived -33°F .

NATIVE HABITAT: *Pyrus calleryana* is native to Korea and China. Introduced 1908. 'Bradford' was raised from seed purchased in 1919 from Nanjing, China. The original reason for introducing *P. calleryana* was to breed fireblight resistance into the fruiting pears. This never materialized but the original effort resulted in several ornamental trees.

RELATED SPECIES:

***Pyrus communis* L. — Common Pear**
(pī'rus kom-mū'nīs)

LEAVES: Alternate, simple, orbicular-ovate to elliptic, 3/4 to 3"(4") long, up to 2" wide, acute or short acuminate, subcordate to broad-cuneate, crenate-serrulate, glabrous or villous when young, lustrous dark green; petiole—1 to 2" long.

BUDS: Imbricate, conical, sharp-pointed, smooth or slightly hairy, terminal about 1/3" long, laterals—small, generally divergent and not flattened or at times on vigorous shoots both flattened and appressed.

STEM: Stout, glabrous or slightly downy, yellowish green or sometimes with tinge of brown; stubby-branched, slow-growing fruit spurs abundant.

BARK: Grayish brown, smooth on young branches, with age longitudinally fissured into flat-topped ridges which are further broken by transverse fissures into oblong scales.

FRUIT: A large fleshy pome, top-shaped to rounded, green to yellowish green.

Pyrus communis, Common Pear, is only mentioned here because it is sometimes trained as an espaliered plant. Tremendous fireblight susceptibility and not recommended for ornamental purposes although the white, 1 to 1 1/2" diameter flowers are quite showy and malodorous. Very early-flowering and I have seen it in full flower on February 22 at Savannah, GA, usually March 1–15 in Athens, GA. Tends to seed and can form thickets. Fall color is sometimes excellent red to maroon and usually in mid-November (Athens). Typically, pyramidal habit, oblong-oval at maturity, 20 to 30' high, 2/3's as wide. National champion 59' by 61' in Waitsburg, WA. Europe, western Asia. Long cultivated. Escaped and naturalized. Zone 4 to 8(9).

***Pyrus kawakamii* Hayata** (was told that this species is now *P. koehnei* C.K. Schneid. but GRIN does not recognize this and lumps *P. kawakamii* with *P. calleryana*) — Evergreen Pear
(pī'rus kaw-a-cam'ē-ī)

LEAVES: Alternate, simple, evergreen, ovate to obovate, 2 to 4" long, finely and regularly serrate, leathery lustrous dark green; petiole—1 1/4" long.

Pyrus kawakamii, Evergreen Pear, is a small rounded evergreen tree that offers abundant white flowers in late winter or early spring. Tends toward a large shrub and the branches droop and sprawl. Used on the West Coast, particularly California. I have seen a few trees on the Georgia coast but they were decimated by fireblight. The branches

may develop thorns. Fruit is globose, glabrous, about 1/2" across and inedible. Dr. John Ruter has a hybrid between this and *P. calleryana* with a tight conical habit. Native to China, Taiwan. Zone 8 to 10.

Pyrus pyrifolia (Burm. f.) Nak. — Chinese Sand Pear
(pī'rus pī-ri-fō'li-a)

LEAVES: Alternate, simple, ovate-oblong, 2 3/4 to 4"(5") long, about half as wide, acuminate, rounded or rarely subcordate, glabrous, margins conspicuously bristle-tipped, lustrous dark green above, petiole—1 1/4 to 1 3/4" long.

Pyrus pyrifolia, Chinese Sand Pear, is a rather large (40'), pyramidal-rounded tree that literally explodes into a white blanket in April. The tree reminds of a white cloud. Flowers are 1 to 1 1/2" across in 6- to 9-flowered corymbs. The globular, 1 1/4" long and wide fruits are brownish and spotted with white, quite hard and gritty. The lustrous dark green leaves turn excellent orange-red in fall. Wilson introduced it in 1908 when collecting for the Arnold and a magnificent specimen from his collection was located along the Chinese walk. Have read size descriptions of 15 to 40'. Central and western China. Zone 5 to 7.

Pyrus salicifolia Pall. — Willowleaf Pear, Willow-leaved Pear
(pī'rus sal-is-i-fō'li-a)

LEAVES: Alternate, simple, narrow-lanceolate, 1 1/2 to 3 1/2" long, 1/3 to 2/3" wide, tapering at both ends, entire or sparsely toothed, covered with gray down when young, later upper surface shining green, lower pubescent; petiole—1/2" or less long.

STEM: Covered with a grayish white pubescence which falls away with age.

Pyrus salicifolia, Willowleaf Pear, reaches 15 to 25' and possesses graceful, silvery gray, willow-like leaves. Unfortunately, it is very susceptible to fireblight and is seldom seen in cultivation in the United States. I learned this tree in my plant materials course at Ohio State in 1962 and did not see it again until 1981 at Bodnant Garden, Wales. Habit is oval rounded with graceful arching branches. 'Pendula' with elegant drooping branches is probably more common in cultivation than the species and, by some, is considered similar to the species. 'Silver Frost' is described as broadly weeping to pendulous, 12 to 15' high, 10 to 12' wide, with silver-gray foliage; I suspect it may be 'Pendula' with a fancy name. Flowers are cream to greenish white, 3/4" diameter, and closely packed 6 to 8 in small, rounded corymbs. Fruits are brown, typical pear shape (top-shaped), and 1 to 1 1/4" long and wide. Silver Ball™ is a new introduction with silver-gray leaves, compact rounded habit, 12' by 12'; the branches are fine-textured; pretty accent tree; from Landscape Plant Development Center, hybridized by Dr. Harold Pellett; flowers listed as white; fall color, yellow-orange. Southeastern Europe, western Asia. Introduced 1780. Zone 4 to 7.

Pyrus ussuriensis Maxim. — Ussurian Pear
(pī'rus ū-sör-ē-en'sis)

LEAVES: Alternate, simple, orbicular-ovate to ovate, 2 to 4" long, acuminate, rounded or slightly cordate, finely and regularly bristle-toothed, glabrous, lustrous dark green; petiole—1 to 2 1/4" long.

Pyrus ussuriensis, Ussurian Pear, is the hardiest of all pears. The habit is dense, rounded, 40 to 50'; the leaves are a handsome, glossy dark green in summer changing to red and reddish purple in the fall. Flowers may be faintly pink in bud, finally white, 1 1/3" across, April–May. The fruit is a (5/8")1 to 1 1/2"(2 1/2") diameter, greenish yellow, subglobose pome. It, along with *P. calleryana*, is the least susceptible to fireblight. For colder climates it would prove a valuable ornamental. Truly a handsome ornamental tree but has never been developed like *P. calleryana*. 'McDermind' is a seed-produced cultivar useful for shelterbelts and wildlife food (1 to 1 1/2" diameter fruits), released in 1990 by USDA-SCS-PMC, Bismarck, SD. Mountain Frost® ('Baifrost') has a more vigorous, upright, growth habit, 20 to 30' by 15 to 20', glossy dark green foliage, yellow in fall, and white flowers; 3/4" diameter fruit is sparsely produced; Bailey Nurseries introduction. Prairie Gem® ('MorDak') is oval in youth, globose to rounded with age, to 25' by 25' or greater; excellent lustrous dark green leaves turn golden yellow in autumn; the 1 1/4" diameter fruits only produced if cross-pollinated; from Dr. Dale Herman, North Dakota State University. A tree in the Milliken Arboretum has not performed well. Flowers not as profuse as *P. calleryana* types and come before or with the foliage. Also defoliated on November 13, 2004 from leaf disease while 'Edgewood' (next to it) was green and completely foliated. Does not grow with gusto and apparently high night temperatures are the culprits. On March 21, 2009 at Milliken completely leafed out, a few residual white flowers; actually ahead of *P. calleryana* types. Zone 3. Has, however, produced abundant fruits. Northeastern Asia. Introduced 1855. Zone 3 to 6(7).

Quercus L. — Oak

FAMILY: Fagaceae

The purest of Noble Trees with the umbrella spreading far to include diminutive, scrubby, shrubby, evergreen types with leaves similar to holly, all permutations between, with 500 species, deciduous and evergreen, distributed worldwide. The fruit, an acorn, with the nut covered by a cap of scales, termed an involucre. Leaves always alternate, buds imbricate, usually with a cluster of buds toward the stem end. Leaves may be entire, serrated, lobed, spiny. . . . Two great groups: Red/Black with acorns ripening in 2-years; white in a single season. Hybrids occur only within Red/Black or White. Probably the best genus for general use across the United States. Traveling from Minnesota (red oak) to Florida (live oak), oaks will be shadowing your car. The Sudden Oak Death, identified in California, killed over a million native oak and tanoak trees in that state. *Phytophthora ramorum* is the causal organism. Concerns about its spread into the eastern/southern forests appear unfounded. Numerous host plants carry the disease. Abundant information is available on the web. Type "Sudden Oak Death" and your computer will burp!

The International Oak Society, www.internationaloaksociety.org, offers annual meeting, publications, seed exchanges, taxonomic database, cultivar registration, et al. A membership fee is charged. A 2003 publication, *Field guide to oaks of eastern North America*, Diane Publishing Co., Darby, PA has great photos and knowledgeable text. I utilized the reference on many occasions.

Quercus acutissima Carruth. — Sawtooth Oak

(kwēr'kus a-kū-tis'i-ma)

FAMILY: Fagaceae

LEAVES: Alternate, simple, obovate-oblong to oblong, 3 1/2 to 7 1/2" long, 1 to 2 1/4" wide, acuminate, broad-cuneate or rounded at base, serrate with bristle-like teeth terminating the 12 to 16 parallel veins, lustrous dark green, glabrous above, glabrous beneath except axillary tufts of hairs, pubescent when unfolding; petiole—3/4 to 1"(2") long; leaf looks like a *Castanea* leaf in many respects and is often confused with same.

BUDS: Imbricate, pubescent, almost woolly, grayish brown, 1/4 to 3/8"(1/2") long, edges of scales membranous and gray pubescent, lower scale darker brown, creating two-toned effect; somewhat similar to *Q. velutina* in appearance, usually larger but not as angled.

STEM: Gray-brown, glabrous.

SIZE: 40 to 60' in height; I have seen trees taller than wide and others wider than tall; probably great variation in seed-grown material although the trend is toward a broad, rounded outline; amazing 52' high by 42' wide specimen in Morton Arboretum.

HARDINESS: Zone (5)6 to 9.

HABIT: Dense, broad pyramidal in youth; varying in old age from oval-rounded to broad-rounded with low-slung, wide-spreading branches.

RATE: Medium to fast, in 16 years grew 32'; in Wichita, KS tests averaged 2'3" per year over a 7 year period; one of the fastest growing oaks particularly in youth; direct seeded into Mississippi floodplain, plants grew 28 to 34' in 14 years; *Q. nuttallii* only 23' on average; see *Tree Planters Notes* 36:3–5 (1985).

TEXTURE: Pleasantly medium in foliage, medium to medium-coarse in winter.

BARK: Deeply ridged-and-furrowed, on old trunks appearing almost corky, ash brown.

LEAF COLOR: Dark lustrous green in summer; often a good clear yellow to golden brown fall color, developing late, often in November; leaves open a brilliant yellow to golden yellow in spring, in late March–early April, Athens.

FLOWERS: Male, in 3 to 4" long slender golden catkins in late March–early April with the emerging leaves.

FRUIT: Acorn, sessile, involucre with long, spreading and recurving scales, enclosing about 2/3's of the nut, about 1" long, often heavy crops are borne, nut about 3/4" long, lustrous rich brown, among the first acorns to ripen and fall; have clocked mature acorns on the ground by late September in Athens; have read report that acorns take two years to develop but have not observed young acorns being carried through the winter.

CULTURE: Easily grown, transplants readily, grows off quickly; I have seen it over a wide geographic area and it prefers acid, well-drained soils but appears quite adaptable; may develop chlorosis on high pH soils; thrives in the heat of the South; have observed dieback in recent years in Zone 7; related to hot, exceedingly dry summers.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Handsome, wide-spreading, clean-foliaged shade or lawn tree; could be used more than it is especially in South where it is fast-growing; Williams et al., *J. Arboriculture* 21:118–121 (1995), reported superior performance of *Q. acutissima*, and also *Q. montana*, *Q. lyrata*, and *Q. shumardii* in Auburn University tests; hardiness reports are somewhat conflicting and I estimate it will withstand –20°F once established; at a conference in Lincoln, NE, where I lectured, a gentleman mentioned that the tree is growing in Blair, NE where winters can be extremely harsh; successfully growing at Morton Arboretum, Lisle, IL; in spring the tree is covered with pendent, golden, male catkins which are quite attractive; old leaves will persist on young trees throughout the winter; it also fruits heavily in the South showing an alternate year bearing tendency; considered a source of nutrition for wildlife; acorns are in certain years so abundant as to cover the ground in a solid mantle.

CULTIVARS:

var. *chenii* (Nak.) Camus—Similar to the above, although it has been listed as a separate species, *Q. chenii* Nak.; the obovate leaves are glabrous, glossy dark green; the acorns smaller with more slender scales; southern and central China.

'Gobbler'—The result of open-pollinated progeny that produce early and abundant acorns for wild turkey food.

PROPAGATION: Sow in fall, germination occurs in spring, root emerges without cold treatment; shoot requires cold.

ADDITIONAL NOTES: Shows strong juvenility and young trees may hold the leaves all winter. New leaves emerge a light yellow and provide a golden glow to the entire tree. Two worthwhile references that describe cultivars of the various oaks are McArdle and Santamour, "Cultivar Checklist of White Oak Species (excl. *Quercus robur* L.)," *J. Arboriculture* 11(10):307–315 (1985) and same authors, "Cultivar Checklist of English Oak (*Quercus robur* L.)," *J. Arboriculture* 13(10):250–256 (1987).

Sternberg, *American Nurseryman* 172(2):33–45 (1990), presents a fine treatise on oak taxonomy and hybridity. Sternberg's premise is that there are many hybrid species with landscape potential. I believe oak vegetative propagation techniques will have to become mainstream to insure commercial success. To a degree, cutting propagation has succeeded and several own-root oaks are now in commerce.

NATIVE HABITAT: Japan, Korea, China, Thailand, Himalaya. Introduced 1862.

RELATED SPECIES:

Quercus variabilis Bl., (kwēr'kus vār-i-ab'-i-lis), Oriental Oak, Chinese Cork Oak, is a large (60 to 70'), fairly open tree with foliage similar to *Q. acutissima* except the upper surface is glossy dark green and the underside of the leaf is clothed with a distinct whitish tomentum and the teeth are shorter. Acorns are ovoid to subglobose, enclosed for most of their length by the cap made up of long, curled scales, 3/4" long, ripen in second year. The bark is very corky, deeply ridged-and-furrowed and up to 4" thick. Seldom housed in North American collections. I actually learned this tree in the woody plants courses at Ohio State where a tree grew on the Oval. Native to northern China, Korea, Japan, Taiwan. Introduced 1861. Zone 5 to 7.

Quercus variabilis

***Quercus alba* L. — White Oak**

(kwēr'kus al'ba)

FAMILY: Fagaceae

LEAVES: Alternate, simple, obovate to oblong-obovate, 4 to 8 1/2" long, about one-half as wide, apex abruptly acute, narrowed at cuneate base, with 5 to 9 oblong and obtuse, entire lobes, sinus narrow and deeply cut toward the midrib and also wider and more shallow in depth, dark green to almost dark blue-green above, pale or glaucous beneath; petiole—1/2 to 1" long, yellowish green.

BUDS: Imbricate, broadly ovate, blunt, reddish brown to brown in color, 1/8 to 1/4" long, sometimes slightly hairy especially at ends of bud scales.

STEM: Stout, brown to purple, angled, sometimes covered with a waxy grayish bloom.

SIZE: 50 to 80' high and wide; can grow over 100' in the wild; national champion is 86' by 116' wide in Lawrenceville, VA.

HARDINESS: Zone 3 to 9.

HABIT: Pyramidal when young, upright-rounded to broad-rounded with wide-spreading branches at maturity; very imposing specimen when full grown; one of the most handsome oaks.

RATE: Slow to medium, 12 to 15' over a 10 to 12 year period, very slow after first 20 to 30 years.

TEXTURE: Medium in leaf, medium to coarse in winter but with a strong, bold appearance.

BARK: On old trunks light ashy gray, variable in appearance, often broken into small, vertically arranged blocks and scales, scaly on the surface; later irregularly plated or deeply fissured, with narrow ridges; sometimes rather smooth and gray in spots; this is caused by a fungus.

LEAF COLOR: Grayish and pinkish when unfolding changing to dark green in summer, almost tends toward a blue-green; fall color varies from brown to a rich red to wine color and lasts for a long period of time; in falls of 1988 and 1996 I saw the best fall color, a rich reddish purple on many White Oaks in the South; in fall 2006, Bonnie and I were driving the Blue Ridge Parkway in southwest Virginia where White Oak is common and noted the great red to deep, almost maroon, fall colors. If only this species could be easily propagated by vegetative (cuttings) means, there would be an avalanche of introductions.

FLOWERS: The following discussion concerns the flowers of the genus *Quercus* and is applicable to most species covered in this text. Monoecious, appearing on the old or new growth; staminate catkins pendent, clustered; individual flowers comprising a 4- to 7-lobed calyx which encloses 6 stamens, rarely 6 to 12; pistillate flowers solitary or in few to many-flowered spikes from the axils of the new leaves; individual flowers consisting of a 6-lobed calyx surrounding a 3- (rarely 4- to 5-) celled ovary, the whole partly enclosed in an involucre.

FRUIT: Nut, solitary or paired, sessile or short-stalked, 3/4 to 1" long, ovoid-oblong, enclosed for 1/4 to 1/3 of its length in a light chestnut brown, bowl-like cap (involucre) with raised "bumpy" scales rather than smooth overlapping scales like *Q. rubra*, nut colors a deep chocolate brown, ripens the first year.

CULTURE: Transplant balled-and-burlapped as a small tree; found on many types of soil although performs maximally in deep, moist, well-drained soils; prefer acid soils, pH 5.5 to 6.5; full sun; prune in winter or early spring. There is a delicate balance in forest situations and when man encroaches and builds roads and houses in White Oak timber the trees often gradually decline and die. This is, in part, due to compaction, ruination of mycorrhizal associations and removal of the recycled organic matter from under the trees.

DISEASES AND INSECTS: The following is a list of problems reported occurring on oaks: anthracnose, bacterial leaf scorch caused by *Xylella fastidiosa* (*Q. alba*, *Q. imbricaria*, *Q. palustris*, and *Q. rubra*, also *Q. falcata*, *Q. laurifolia*, and *Q. nigra*), basal canker, canker, leaf blister, leaf spots, powdery mildew, rust, twig blights, wilt, wood decay, shoe-string root rot, various galls, scales, gypsy moth, yellow-necked caterpillar, pin oak sawfly, saddleback caterpillar, oak skeletonizer, asiatic oak weevil, two-lined chestnut borer, flatheaded borer, leaf miner, oak lace bug and oak mite; in spite of this inspiring list of pests, White Oak is a durable, long-lived tree.

LANDSCAPE VALUE: It is doubtful if this will ever become a popular ornamental tree unless it is native in a specific area; production is difficult, growth is slow, and transplanting can be a problem; a majestic and worthwhile tree for large areas; the state tree of Illinois; actually among the most handsome of oaks.

CULTIVARS:

'Southern Cross' (PP 10,853)—Unique hybrid, actually back-cross of (*Q. alba* × *Q. michauxii*) × *Q. michauxii* with rapid growth rate (3'/year); strong central leader, graceful branching habit, and tolerance of periodically flooded soil; introduced by Martin G. Ludeke, Charlottesville, VA; original tree was 46' high, 40' wide in 16 years; has been grafted on white oak.

PROPAGATION: Seed requires no special treatment; direct sow after collection.

ADDITIONAL NOTES: The most important species of the White Oak group. The wood is used for furniture, flooring, interior finishing, boat building, wine and whiskey casks. The acorn is edible and is eaten by many kinds of birds and mammals. Best to boil in water to remove tannins. Difficult to pen my emotional ties to this species. A White Oak dominated forest is beautiful year round. From the south side (I believe) of Biltmore House, from the overlook, is a view to Mt. Pisgah and other mountains. In the foreground, dominating the rolling hills, are numerous open-grown White Oaks with unshaven gray fuzz in spring, dark green in summer, shades of bronze to red in fall, and gray in winter. If the reader has not observed this facet of the estate, take the time to savor the beauty during the next visit.

NATIVE HABITAT: Maine to Florida, west to Minnesota and Texas. Introduced 1724.

RELATED SPECIES:

***Quercus bicolor* Willd. — Swamp White Oak**
(kwēr'kus bī'kul-ēr)

LEAVES: Alternate, simple, oblong-obovate to obovate, 3 to 7" long, 1 1/4 to 4" wide, acute or rounded cuneate, coarsely sinuate-dentate with 6 to 10 pairs of coarse, obtuse teeth, or sometimes lobed halfway to the midrib, lustrous dark green above, whitish tomentose or grayish green and velvety beneath, midrib yellowish, leathery in texture; petiole—1/2 to 3/4" long, yellowish.

BUDS: Imbricate, broadly ovate, light chestnut brown, 1/8 to 1/4" long, coated with pale down above the middle; clustered buds often have house needle- to strap-like appendages.

STEM: Stout to slender, yellowish brown to reddish brown, glabrous.

BARK: Flaky, grayish brown, divided by deep, longitudinal fissures into rather long, flat ridges; on old trunks rugged and handsome; the flaking, scaly bark is evident on young trees with 3 to 5" diameters; this is a good characteristic to separate it from *Q. alba*.

Quercus bicolor, Swamp White Oak, grows 50 to 60' in height with an equal or greater spread forming a broad, open, round-topped crown and a short, limby trunk. The acorn is about 1" long, usually paired, covered about 1/3 by the involucre, shining light brown nut, borne on slender 1 to 4" long peduncles. Found in the wild in low lying and more or less swampy situations, often occurring in moist bottomlands and along the banks of streams. Requires acid soil. I have observed very severe chlorosis on this species. There are mixed answers as to the ease of transplanting; several nurserymen said easy, others difficult; generally

considered easier than *Q. alba*. Many beautiful specimens at Mt. Airy, Cincinnati, OH, fully 60 to 80' high and 60 to 70' wide. On a rainy October day I walked Minutemen National Park, Concord, MA, and witnessed along the Concord River the largest *Q. bicolor* to date with coarse-textured, blackish, deeply ridged-and-furrowed bark and elephantine trunk (size), a tinge of yellow-bronze fall color, and no humans in sight, the tree was mine to savor, appreciate and respect. The national champion is 93' by 102' in Franklin Township, NJ. Excellent drought resistance is inherent in this species. Winter silhouette is more coarse than *Q. alba* because of the numerous short branches that develop from secondary branches. Normal fall color is yellow but have seen reasonable red-purple. Hybrids between this and *Q. alba* are termed *Q. xjackiana* hort. Oak rough bulletgall wasp is producing woody galls on the stems of *Q. bicolor* and *Q. macrocarpa* in Colorado where both species are utilized for shade trees. Excellent performance at Milliken Arboretum, Spartanburg. Young trees tend to hold leaves into winter, a juvenility response. Native from Quebec to Georgia, west to Michigan and Arkansas. Introduced 1800. Zone 4 to 8.

Quercus cerris L. — Turkey Oak

(kwēr'kus ser'ris)

LEAVES: Alternate, simple, oval or oblong, 2 1/2 to 5" long, 1 to 3" wide, coarsely dentate to pinnately lobed, teeth triangular and acute, rounded to truncate, lustrous dark green above, dull light green and pubescent below, 6 to 10 vein pairs; petiole—variable, 1/8 to 3/4" long.

Quercus cerris is a striking, conical-oblong, haystack-shaped to round-headed, 40 to 60' high and wide tree that shows great adaptability but is unknown outside of arboreta. I have seen superb trees at the Morris Arboretum and Spring Grove. Appears to grow well in clay soils and has withstood -25°F and the droughts of the past 30 years. Leaves hold late and die off green or yellow-brown in fall. The bark is especially noteworthy since it is gray-blackish and occurs in raised checkered plates. The 1" long acorns are enclosed half their length by a cap with reflexed scales. Reminds to some degree of the cap of *Q. acutissima*, only smaller. Acorns are generally sessile and grouped 1 to 4 together. A most handsome form is 'Argenteovariegata' ('Variegata') with creamy white blotches and margins; actually the marginal variegation often reaches to the midrib; appears to be quite vigorous. Beautiful specimens of the species at Knightshayes Garden in Devon, England, last experienced in the sullen light of late March, the massive trunk and muscular branches dominating the meadow that fronts the garden. Great trees are terrific! Southern Europe, western Asia. Introduced 1735. Zone 5 to 7(?).

Quercus falcata Michx. — Southern Red Oak, Spanish Oak

(kwēr'kus fal-kā'ta)

LEAVES: Alternate, simple, obovate to ovate, 5 to 9"(12") long, 4 to 5" wide, either shallowly 3-lobed at the apex or more or less deeply 5- to 7-lobed, often falcate, the terminal lobe sometimes much longer than the laterals, apex acuminate or falcate, base rounded to broadly cuneate, lustrous dark green above, grayish green and tomentose below turning brownish with time; petiole—1 to 2" long, often pubescent, yellowish.

BUDS: Imbricate, 1/4" long, ovoid, acute, dusty reddish brown, pubescent especially toward apex.

STEM: Reddish brown, angled, pubescent or nearly glabrous.

Quercus falcata is one of the most common upland southern oaks and is particularly characteristic of the drier, poorer soils of the Piedmont (Southeast). There are a great number at the University's Botanical Garden and several large specimens on the Georgia campus. Was advised by Bartlett Tree experts that root disturbance/injury during construction may result in decline or death. Apparently, the species is extremely sensitive to root disturbance. The species will grow 70 to 80' and with time forms a rounded outline. The national champion is 123' by 152' in Upton, GA. The leaves hold late and fall color is at best brown, perhaps with a tinge of red. The 1/2" long, subglobose nut is borne either singly or paired. The cap is shallow and sits on the

*Quercus falcata**Quercus falcata*
var. *pagodifolia*

top of the nut. The nut is distinctly striate with alternating, more or less parallel lines of light and dark brown to black. The variety *pagodifolia* Ellis., Cherrybark Oak, Swamp Spanish Oak, has leaves more uniformly 5- to 11-lobed than the species, with the margins of the ribs (lobes) at right angles to the midrib. The sinuses are not as deep as those of *Q. falcata*. Bark is cherry-like, blackish, cross-checked (e.g. blocky) and scaly. National champion is 123' by 122' in Tipton County, TN. The variety is found in a number of bottomland habitats but develops best on loamy ridges. The species is native from New Jersey to Florida, west to Missouri and Texas. Introduced before 1763. Zone (6)7 to 9. The variety runs from Virginia to Florida west to southern Illinois and Arkansas. Introduced 1904. Zone 7 to 9. Neither are common in nursery commerce. Variety *pagodifolia* has possibilities. Variety *pagodifolia* is considered *Q. pagoda* Raf., a distinct species, by some. Indeed the leaf is distinctly unique. I walked the Oconee River floodplain between Green and Oconee Counties in Georgia where the Cherrybark Oak grew in abundance. The long, slender boles extended 40 to 50' without a single branch, the trees easily 80 to 100' high. Walked this area in late August 2008; indeed remarkable trees. In the Georgia trials, Cherrybark Oak forms and maintains a central leader and grows exceptionally fast, 30 feet in 10 years. Leaves persist into winter, which may lessen commercial acceptance. 'QXMTF' (PP 18,495) is a suspected hybrid of *Q. falcata* × *Q. shumardii* characterized by dense pyramidal habit, shiny compact foliage and consistent orange fall color; discovered by Dwayne Moon, GA, in 1977.

RELATED SPECIES:

***Quercus laevis* Walt. — Turkey Oak**
(kwēr'kus lē'vis)

LEAVES: Alternate, simple, obovate, 4 to 14" long, 3- to 7-lobed, lustrous dark green above, glabrous below except for hairs in axils of veins; petiole—less than 3/4" long.

BUDS: Imbricate, long conical, to 1/2" long, gray-brown, pubescent.

Quercus laevis is allied to *Q. falcata* but with petioles 1/2 to 3/4" long and leaves at maturity lustrous and glabrous below. Leaves may develop red to red-brown fall coloration. The tree is common in the sand hills of the South where it grows on dry, sandy soils and well-drained ridges. The leaves hang perpendicular to the ground.

About the only oak with this leaf shape (form) to have the downward-pointing leaf. Tree grows 30 to 40' high under cultivation, often

limited by habitat extremes in the wild. Co-national champions are 73'

by 44' in Wayne, GA and 63' by 53' in Moore, NC. Bark is thick and blackish

with deep, irregular furrows and blocky ridges. Acorn caps 3/4 to 1 1/4" wide, on 1/5"

long peduncles, covering about 1/3 of acorn. Virginia, North Carolina to Florida and Louisiana. Introduced around 1834. Zone 7 to 9.

Quercus georgiana M.A. Curtis — Georgia Oak

(kwēr'kus jôrj-ē-ā'na)

LEAVES: Alternate, simple, 1 1/4 to 4 1/2" long, 1 to 3 3/4" wide, 3- to 6(7)-lobed, usually with one bristle per lobe, acute with sharp bristle, cuneate, lustrous dark green above, glabrous, paler below with tufts of hairs on main vein axils; petiole—1/4 to 1/2" long.

BUDS: Narrow ovoid to oval, dark brown, often with some luster, pubescent often at their tips, 1/8 to 1/4" long.

STEM: First year—slender, shiny brown, glabrous; second year—gray-brown with numerous small lenticels.

Quercus georgiana is a small, 15 to 30' high and wide tree that grows naturally on granitic outcrops in South Carolina, Georgia, and Alabama. It is often stunted in this habitat but under cultivation makes a rather handsome densely branched tree with beautiful lustrous dark green summer foliage and red to reddish purple fall color. The bark is dark gray, thin and smooth becoming scaly with maturity. Acorns (two years to mature) average 1/2" long, the cap covering about 1/4 of the dark brown nut. The national champion is 59' by 65' in Clarke, GA. Several 25 to 30' trees on the Georgia campus make one believe that the species has possibilities as a small lawn, planter or park tree. Easily grown from seed planted in fall. Rehder places this as a species related to *Q. palustris*. Hybrids between the two might yield useful offspring. Introduced 1876. Zone (5)6 to 8.

Quercus hemisphaerica Bartr. — Laurel Oak

(kwēr'kus hem-i-sfer'ik-a)

LEAVES: Alternate, simple, evergreen until February in Athens, lanceolate, elliptic to oblanceolate, obovate, or oblong-obovate, 1 1/4 to 4" long, 1/2 to 1 1/4"(2") wide, acute or obtuse, usually with a bristle-tip, cuneate or obtuse at base, entire or with a few shallow lobes or teeth, thick, leathery, often undulating, lustrous dark green, glabrous, lighter green below; petiole—1/4" long, yellowish.

BUDS: Imbricate, shiny reddish brown, 1/8 to 1/4" long, essentially glabrous, small for oak buds, similar to buds of *Q. phellos*, *Q. nigra*, and *Q. laurifolia*.

STEM: Gray-brown, glabrous, dotted with small lenticels.

Quercus hemisphaerica is reasonably common throughout the coastal plain in the South. The habit is pyramidal-rounded with ultimate height ranging from 40 to 60' and spread of 30 to 40'. National champion is 98' by 108' in Alachua County, FL. Several trees on the Georgia campus are exceedingly handsome and are thriving in less than ideal locations. The lustrous dark green leaves persist into February and later, depending on the severity of winter. Acorns are short-stalked (virtually sessile), the nut subglobose to ovoid, about 1/2" long, enclosed 1/4 to 1/3" by the saucer-shaped cap.

It has found favor as a street tree in many cities of the South. It is not as long lived or sturdy as *Q. phellos* and *Q. virginiana* but because of smaller size is a good choice for residential landscapes. There are no special soil requirements or pests. 'Darlington' is more compact and the leaves more persistent than the species. I have observed the above cultivar (debatable as to cultivar status, name derived from proximity of trees to Darlington, S.C.) as far north as Cincinnati, OH where it was distinctly deciduous. In the wild occupies well-drained, sandy soil, established dune areas, scrub oak sandhills, stream banks, occasionally in mixed woods. The rapid growth makes it a worthwhile choice for landscape use.

*Quercus laurifolia*

Great confusion abounds concerning the existence of this oak and *Quercus laurifolia* Michx., Swamp Laurel Oak or Diamondleaf Oak. Many authorities considered *Q. laurifolia* the major species with *Q. hemisphaerica* simply lumped thereunder. Current status (see R.K. Godfrey, 1988. *Trees, shrubs and woody vines of northern Florida and adjacent Georgia and Alabama*. The University of Georgia Press, Athens, GA.) separates the two and possibly with good reason. *Quercus laurifolia*, as I have observed it on the Georgia campus, loses all the leaves by December–January and is more open in outline. Also, the leaves are larger and although many are similar to *Q. hemisphaerica*, others are almost diamond-shaped. The apices of the leaves are more obtuse, while those of *Q. hemisphaerica* are acute. Buds are 1/8 to 1/4" long, ovoid, shiny rich brown, appearing 5-sided when viewed from apex down. Acorns are short-stalked, about 1/2" long, much like *Q. hemisphaerica*. Probably about same landscape size as *Q. hemisphaerica*. An older specimen on the Georgia campus is 80' high. National champion is 130' by 81' in Richland, SC. Native to coastal plain and piedmont from southern New Jersey to Florida to east Texas and Southeast Arkansas. Zone 6 to 9.

Quercus imbricaria Michx. — Shingle Oak, also known as Laurel Oak

(kwě'r'kus im-bri-kā'ri-a)

LEAVES: Alternate, simple, oblong or lanceolate, 2 1/2 to 6" long, 1 to 3" wide, acute at apex with bristle-like tip, revolute margin, lustrous dark green and glabrous above, pale green or brownish and pubescent beneath; petiole—1/4 to 5/8" long.

BUDS: Imbricate, ovoid, sharp-pointed, 1/8 to 1/4" long, brownish, often slightly hairy.

STEM: Slender, green-brown, lustrous, glabrous, angled.

SIZE: 50 or 60' in height, developing a comparable or slightly greater spread, can grow 80 to 100' in height; national champion is 105' by 62' in Cincinnati, OH.

HARDINESS: Zone 4 to 8.

HABIT: Pyramidal to upright-oval in youth assuming a haystack-shaped to broad-rounded outline in old age, often with drooping, lower, lateral branches.

RATE: Slow to medium, 1 to 1 1/2' per year over a 10 to 20 year period.

TEXTURE: Medium in leaf, medium-coarse in winter.

BARK: Gray-brown, close, eventually with broad, low ridges separated by shallow furrows.

LEAF COLOR: Reddish when first unfolding changing to a lustrous dark green in summer and assuming yellow-brown to russet-red colors in fall; old leaves often persisting through winter.

FRUIT: Nut, short-stalked, subglobose, about 5/8" long, the nut enclosed 1/3 to 1/2 in a thin, bowl-shaped cap with appressed, red-brown scales, maturing second year.

CULTURE: Transplants with less difficulty than many oaks; prefers moist, rich, deep, well-drained, acid soil although is tolerant of drier soils; somewhat tolerant of city conditions; full sun.

DISEASES AND INSECTS: See under White Oak.

LANDSCAPE VALUE: Does quite well in the Midwest and has been used for lawn, street, park, golf course and other large areas; accepts pruning very well and can be used for hedges; the leaves persist into winter and aid in screening or breaking the wind; does not perform as well in Zone 7(8) as further north.

PROPAGATION: Seed, stratify in moist sand or peat for 30 to 60 days at 41°F or directly sow outside and germination will take place in spring.

ADDITIONAL NOTES: The wood of Shingle Oak was used to make shingles; hence, the common name.

NATIVE HABITAT: Pennsylvania to Georgia, west to Nebraska and Arkansas. Grows in rich soils along streams, rich slopes, dry uplands. Introduced 1724.

RELATED SPECIES: At least in appearance.

***Quercus oglethorpensis* Duncan** — Oglethorpe Oak
(kwēr'kus ō-gle-thōrp-en'sis)

LEAVES: Alternate, simple, elliptic to narrow elliptic, seldom narrow obovate to obovate, entire, occasionally with several humps or shoulders, obtuse, with *no* bristle tip, cuneate, dark green above and glabrous, stalked, stellate hairs below; petiole—1/8 to 1/4" long.

BUDS: Reddish brown, pubescent, ovoid-blunt, 1/8 to 3/16" long, with numerous narrow stipular appendages subtending buds.

STEM: Reddish brown, lustrous, glabrous, dotted with small circular light gray lenticels.

Quercus oglethorpensis, Oglethorpe Oak, is only mentioned because of the somewhat similar leaf shape. The apex of the leaf is *not* bristle-tipped like *Q. imbricaria*. The species is a White Oak group member with scaly, gray bark, stiff, coarse, twiggy branches and long-term leaf retention. Fall color is bronze-brown and brown leaves are retained through winter. Trees are irregular pyramidal when young, more rounded with age. Probably 30 to 40' under landscape conditions. The national champion is 64' by 82' in Oglethorpe, GA. Dark brown-black acorns average 1/2" long and are covered 1/3 or more by the appressed scales. Found in the wild on poorly drained soils and adjacent slopes. Piedmont of eastern Georgia and western South Carolina, Mississippi and Louisiana. Discovered and named by the late Dr. Wilbur Duncan, Professor of Botany, University of Georgia, and one of the best field taxonomists I have actively interacted with. Several trees grow on the Georgia campus and hold their leaves into late fall–winter. From a distance, they are similar to *Q. imbricaria*. Zone 6 to 9.

***Quercus lyrata* Walt.** — Overcup Oak
(kwēr'kus lī-rā'ta)

LEAVES: Alternate, simple, obovate-oblong, 6 to 8" long, 1 1/2 to 3"(5") wide, acute or obtuse, cuneate at base, deeply lyrate-pinnatifid, with 3 to 5 pairs of obtuse, acutish lobes, the 2 lower pairs smaller and triangular and separated from the upper pairs by wide sinuses, the large middle pair usually with a small lobe on the lower margin, the terminal lobe usually 3-lobed, dark green and glabrous above at maturity, white tomentose beneath or green and pubescent; petiole—1/2" long, either glabrous or pubescent, orangish yellow.

BUDS: Imbricate, brown, 1/8 to 1/4" long, reminiscent of Swamp White Oak buds, gray-brown, stipular appendages nestled in cluster of terminal buds.

STEM: Stout, angled, gray-brown, small grayish lenticels, glabrous or slightly pubescent.

Quercus lyrata, at one time an obscure native species, has become a mainstream

landscape tree in the Southeast. The habit in youth is pyramidal-oval and oval-rounded to rounded at maturity. The branching is very uniform and a row of seedling-grown, 50 to 60' high trees on the Georgia campus are quite similar.

The lower branches are upswept so minimal pruning is required compared to *Q. palustris*. These trees are growing in confined spaces on a slope and are thriving. Bark is reminiscent of White Oak from a distance, perhaps not as scaly, gray to brownish gray. The leaves are dark green and somewhat leathery. They turn a rich yellow-brown to tannin brown in fall and abscise fully and earlier than those of other oaks. The common name is derived from the cap that almost completely encloses the nut. The nut is sub-globose to rounded, 3/4 to 1" high and wide, usually covered by the cap except for a small window at the apex; other times the cap covers 3/4's of the nut. Acorns mature in one year. It is a bottomland species in the wild where it is found in sloughs and backwater areas. Withstands considerable flooding. The expected landscape size is 40 to 60' high and wide. National champion is 109' by 102' in Southampton, VA. It might be worth considering for especially difficult sites. With selection and propagation this could become an important landscape tree. I have "pushed" this species to any nurseryman who would listen. Several have taken the lead and are producing it. Significantly easy to transplant compared to White Oak.

Might add, do not remember an unworthy specimen. Shown superior in a 13 year evaluation of shade trees at Auburn; see *J. Arboriculture* 21:118–121 (1995). Also, Dirr, *Nursery Manager* 7(6):42 (1991) for a discussion of the species. Has taken off in commerce because of uniformity of habit from seed, fast growth, ease-of-transplanting, and adaptability to inhospitable soil conditions. Mike Glenn, owner, Select Trees, told me it was the most uniform species oak when grown from seed. In fact, Select Trees introduced an own-root, clonal selection, Highbeam® ('QLFTB', PP 13,470) with superior habit, yellow-orange-red fall foliage and rootability. Large old trees on the University of North Carolina campus and the Coker Arboretum. Also, a vigorous, beautiful hybrid of *Q. lyrata* and *Q. michauxii*, *Q. xtottentii*, grows at the University's Botanical Garden. New Jersey to Florida, west to Missouri and Texas. Introduced 1786. Zone 5 to 9.

Quercus macrocarpa Michx. — Bur Oak, also called Mossycup Oak

(kwēr'kus ma-krō-câr'pa)

LEAVES: Alternate, simple, obovate to oblong-obovate, 4 to 10"(12") long, about 1/2 as wide, cuneate or rarely rounded at base, lower portion of leaf with 2 to 3 pairs of lobes, upper 5 to 7 pairs of ovate-obtuse lobes, dark green and often lustrous above, grayish or whitish tomentulose beneath, leaf shaped like a base fiddle; petiole—1 1/4" long, downy.

BUDS: Imbricate, conical to broadly ovate, sharp-pointed or blunt, 1/4 to 3/8" long, pale pubescence covering entire bud, often with stipular structures arising out of clustered buds.

STEM: Stout, yellowish brown, smooth or downy, stems on some trees developing corky ridges after first year.

SIZE: 70 to 80' in height with an equal or slightly greater spread, can grow to over 100'; co-national champions are 90' by 130' in Boone, MO and 104' and 93' in Woodford, KY.

HARDINESS: Zone 3 to 8.

HABIT: Weakly pyramidal to oval in youth gradually developing a massive trunk and a broad crown of stout branches; impressive as an open-grown specimen of the prairie.

RATE: Slow, over a 20-year period 15 to 20' of growth could be considered average.

TEXTURE: Coarse in all seasons, but majestically so.

BARK: Rough, developing deep ridged-and-furrowed character, usually dark gray to gray-brown in color.

LEAF COLOR: Often lustrous dark green in summer, fall color is dull yellow-green, yellow, to yellow-brown.

FRUIT: Nut, solitary, usually stalked, 3/4 to 1 1/2" long, broadly ovoid, downy at the apex, enclosed 1/2 or more in a deep cap that is conspicuously fringed on the margin, matures in a single season.

CULTURE: Difficult to transplant; adaptable to various soils and is found on sandy plains to moist alluvial bottoms; on uplands, limestone soils are favored; succeeds well even in dry, clay soils; more tolerant of city conditions than most oaks; full sun.

DISEASES AND INSECTS: See under White Oak; witnessed some cicada damage to young shoots in early June, 2004 at Spring Grove; in fact, this species was among the hardest hit.

LANDSCAPE VALUE: Probably too large for the average home landscape; however, makes an excellent park or large area tree; very impressive and inspiring tree; there was a specimen in Urbana, IL over 90' tall and estimated at 300 years of age.

CULTIVARS:

Jordan Street® ('Atwood', PPAF)—Beautiful upright spreading habit forming a rounded crown; parent tree about 90' by 75', over 100 years old; strong influence of *Q. macrocarpa* in leaves with *Q. alba* as other parent; leaves are dark green and highly resistant to powdery mildew; withstood -28°F; Herritage® Tree introduction.

Urban Pinnacle™—Narrow, pyramidal habit with dominant central leader; selected for anthracnose and mildew resistance, glossy dark green leaves, narrow habit, and very small, 1/2" acorns; Keith Warren selection, J. Frank Schmidt & Son, Co. introduction in 2009.

PROPAGATION: No pretreatment is required although 30 to 60 days at 41°F in moist sand or peat is suggested.

ADDITIONAL NOTES: I have always been fascinated by variation within a species and when writing the identification features for many of the species in this book I literally cringe at the thought of presenting a stereotyped leaf, bud, stem, etc. I suggest the interested reader consult Dicke and Bagley, *Silvae Genetica* 29:171–196 (1980), for an interesting discussion of variation in Bur Oak. Professor Bagley told me that he has observed acorns on which the involucre is not fringed.

NATIVE HABITAT: Nova Scotia to Pennsylvania, west to Manitoba and Texas. Introduced 1811.

Quercus marilandica Münchh. — Blackjack Oak

(kwēr'kus mar-i-lan'di-ka)

LEAVES: Alternate, simple, broad obovate, 4 to 8" long, often as broad at the 3- to 5-lobed apex, rounded at base, lobes broad, entire or sparingly toothed, lustrous dark green and glabrous above, brownish tomentose beneath, finally almost glabrous and yellowish green; petiole—1/4 to 3/4" long.

BUDS: Imbricate, ovoid, elliptical, strongly divergent, grayish brown, coated with rusty brown hairs, particularly from 2/3's to 1/2 the way from base to apex, 1/4 to 1/3" long.

STEM: Stout, red-brown, pubescent initially, later brown to ash-gray, dotted with numerous small gray-brown lenticels.

Quercus marilandica is usually a scrubby tree with a Hounds-of-the-Baskervilles' gothic habit, the stout branches forming an irregular outline. Often many short branches along the major limbs that create a thicket-type appearance. There is a 40' tree in the Coker Arboretum, UNC, that faces Hillsborough Street, the craggy branches creakily arching forming an irregular oval canopy. Quite easy to spot a Blackjack Oak; once observed, never forgotten. Fall color is at best yellow-brown, occasionally flashes of bronze-red, but not unattractive. Found in infertile, barren soils, often sandy veins, and is a good indicator of soil quality. I occasionally chance upon the species in Georgia and invariably the soils are quite sandy. The tree is often dwarfed by its environment and is somewhat shrub-like but can reach 30 to 40'. National champion is 122' by 49' in Barbour, AL. Acorns range from 3/4 to 1" long, about half as wide, and are enclosed one-half in the yellow-brown cap. Mature in second year. Not a tree that will be found in nursery production but if native certainly worth treasuring. New York to Iowa south to Florida and Texas. Introduced before 1739. Zone 6 to 9.

Quercus montana Willd. (formerly *Q. prinus* L.) — Chestnut Oak, Basket Oak
(kwě'r'kus mon-tan'a)

LEAVES: Alternate, simple, obovate to obovate-oblong, 4 to 6" (12") long, 1 1/2 to 3 1/2" (4") wide, acute or acuminate, cuneate or rounded at base, coarsely and regularly toothed, with 10 to 14 pairs of obtusish, often mucronate teeth, lustrous dark yellow-green, grayish tomentulose beneath; petiole—1/2 to 1" long, yellow and color extends to midrib.

BUDS: Imbricate, 1/4 to 3/8" long, conical, grayish, reddish brown, dusted with pubescence, resembling *Q. rubra* buds in shape and size.

STEM: Stout, glabrous, lustrous brown, dotted with numerous small gray lenticels, somewhat angled with decurrent ridges from sides and base of leaf scar.

Quercus montana, Chestnut Oak, is also called Basket Oak, Rock Oak and Rock Chestnut Oak. This tree reaches 60 to 70' in height with a comparable, but irregular spread. National champion is 99' by 98' in Arnold, MD. The habit is pyramidal, oval to rounded in youth, eventually rounded and relatively dense. The leaves are lustrous dark yellowish green in summer changing to orange-yellow to yellowish brown in fall. One tree in the fair city of Watkinsville, GA turned a reasonable reddish brown. Acorns are borne 1 to 2 on peduncles shorter than the petioles, ovoid, 1 to 1 1/4" high, 3/4" wide, enclosed 1/3 to 1/2 by the tuberculate cap. The nut is a rich dark brown. This is a tree of rocky places and is found on poor, dry, upland sites where it may form pure stands. Maximum growth is made in well-drained soils and other moist sites. It is often found in association with Scarlet and Black Oaks on the rocky slopes of mountains. Have experienced the tree in quantity during my hikes through the southeastern Appalachian mountains. This species can grow 12 to 15' over a 7 to 10 year period. The acorns are sweet tasting and are relished by the gray squirrel, black bear, white-tailed deer and many other forms of wildlife. The bark is brown to nearly black, appearing corky in texture, and on older trees, very deeply and coarsely furrowed. The bark is valuable, being richer in tannin content (11%) than that of any other oak species. A very lovely tree which does exceedingly well in dry, rocky soil. No seed pretreatment is necessary. Have discovered that the species is relatively easy to transplant. Have observed trees in parking lot islands that have prospered. In my opinion a better landscape tree than ever considered. Auburn trials showed this to be a superior species in its 13 year test. *Quercus prinus* L. still surfaces as the scientific name for the species. Often confused with *Q. michauxii* but that species has scaly bark like *Q. alba*. Native from southern Maine and Ontario to South Carolina and Alabama. Cultivated 1688. Zone 4 to 8.

RELATED SPECIES:

Quercus michauxii Nutt., (kwě'r'kus mi-shō'ē-ī),

Swamp Chestnut Oak, Basket Oak, is similar except it occurs in moister soils, grows larger and the involucre scales form a fringe around the rim. The silliness in plant taxonomic circles is evident when *Q. michauxii* has hairs solitary and in clusters of 2 to 8, *Q. montana* in 2 to 5. Who can see them much less count them? For ease of

identification, it might be better lumped with *Q. montana*. Leaves of *Q. michauxii* are, in general, more leathery-textured with greater pubescence on the lower surface. National champion is 140' by 115' in Big Oak Tree State Park, MO. This is a stately tree deserving of greater consideration in contemporary landscapes. The species is successful at the Morton Arboretum, Lisle, IL where over 40' high specimens are growing. A great, 60 to 70' high and wide plant grows in the Coker Arboretum, UNC, 2008. Every time Bonnie and I walk through the Coker I raise the question . . . "Why is this tree not more common in gardens?" Small (4" diameter) trees on the Georgia campus transplanted without difficulty. The bark on young trees is quite scaly. I have collected acorns from the great trees at Brookgreen Gardens, SC and found them easy to germinate and the resultant seedlings display great vigor, i.e., 3 to 4' in a single season. The trees on the November 20th day I witnessed them developed bronze-red fall coloration. Common in low areas, river bottoms, swamp borders and ravines in New Jersey, Delaware to Florida, west to Indiana, Missouri and Texas. Angelor et al., *Tree Physiology* 16:477–484 (1996), showed that neither *Q. michauxii* nor *Q. falcata* var. *pagodifolia* seedlings survived one year of continuous flooding while *Nyssa sylvatica* var. *biflora* and *Liquidambar styraciflua* seedlings survived (~95%) more than two years of flooding. Introduced 1737. Zone 5 to 8(9).

Quercus muehlenbergii Engelm. — Chinquapin Oak, Chinkapin Oak, also called Yellow Chestnut Oak

(kwēr'kus mū-len-bēr'jē-ī)

LEAVES: Alternate, simple, oblong to oblong-lanceolate, 4 to 6 1/2" long, 1/3 to 1/2 as wide, acute or acuminate, usually rounded at base, coarsely toothed, with about 8 to 13 pairs of acute and mucronate often incurved teeth, lustrous dark yellow-green above, whitish tomentulose beneath; petiole—3/4 to 1 1/2" long.

BUDS: Light brown or pale margined, ovoid or conical-ovoid, 1/6 to 1/4" long.

STEM: Glabrous, brown, rounded, slender.

SIZE: 40 to 50' under landscape conditions but can, and often does, grow 70 to 80' tall in the wild, spread is usually greater than height at maturity; national champion is 76' by 69' in Harrison, KY.

HARDINESS: Zone (4)5 to 7.

HABIT: Weakly rounded in youth but of dapper outline; with maturity developing an open, rounded crown.

RATE: Medium in youth, slowing down with age.

TEXTURE: Medium in leaf; medium-coarse in winter.

BARK: Ashy-gray, more or less rough and flaky.

LEAF COLOR: Lustrous dark yellowish green in summer; fall color varies from yellow to orangish brown to brown.

FRUIT: Acorn, subsessile, globose-ovoid or ovoid, 3/4 to 1" long, enclosed about 1/2 by the thin cap, scales small, depressed, maturing the first year.

CULTURE: Like many oaks, somewhat difficult to transplant; in the wild is found on dry limestone outcrops and soils with an alkaline reaction; prefers rich bottomlands and there attains its greatest size.

DISEASES AND INSECTS: None particularly serious.

LANDSCAPE VALUE: Actually quite an attractive tree especially in old age; if native in an area it is worthwhile saving; I doubt if it will ever become a popular landscape tree; in Springfield, IL, I have seen 70 to 80' mammoth specimens with large, bold, scaly, gray trunks and branches; trees are actually inspiring.

PROPAGATION: No seed pretreatment is necessary.

ADDITIONAL NOTES: Distinct species as I studied and understood its nature in the Midwest. By some authorities the name was changed to *Quercus prinoides* Willd. but that species, as grown in Georgia trials, is smaller in all its parts and slower growing. In fact, both grew in proximity with *Q. muehlenbergii* about 6 to 7 times larger in the same time frame. The typical midwestern forms had narrow leaves with coarse teeth as shown in drawings. Apparently some forms are similar to *Q. montana* (*Q. prinus*) and *Q. michauxii*. Experienced

many trees in western Kansas and Oklahoma which provided an indication of drought tolerance. Beautiful tree in North Florida at Charles Webb's garden. In fact, during a fall visit, this species had the cleanest, lustrous dark green foliage and a uniform pyramidal habit. A tree in our Georgia trials has also performed magnificently. I expect variation in characteristics and adaptability because of the extended native range. This, like *Q. lyrata*, has garden potential and perhaps like that species will become more common by the time the 7th edition surfaces.

NATIVE HABITAT: Vermont, Southern Maine to Virginia, west to Minnesota, Nebraska, Texas and Mexico. Introduced 1822.

Quercus prinoides

Quercus myrsinifolia Bl. — Chinese Evergreen Oak

(kwēr'kus mēr-sin-i-fō'li-a)

LEAVES: Alternate, simple, evergreen, ovate to elliptic, 2 1/2 to 4" long, 3/4 to 1 1/2" wide, acuminate, rounded, bristle-tipped serrations, 10 to 16 vein pairs, the midrib scarcely impressed above, lateral nerves very slender, only slightly raised beneath, lustrous medium green above, glaucous green beneath; petiole—1/2 to 3/4" long.

BUDS: Imbricate, slender-conical, gray-brown, pubescent at top, 1/4 to 3/8" long.

STEM: Slender for an oak, shining brown, glabrous, prominently covered with small lenticels.

SIZE: 20 to 30', spread slightly less or similar; have seen mature trees and most were round headed; in Savannah, GA observed many 40' high, oval-rounded trees, also large (50') specimens at U.S. National Arboretum and North Carolina State University Campus.

HARDINESS: Zone (6)7 to 9, the most cold hardy evergreen oak.

HABIT: Small, densely foliated, dapper, round-headed tree that deserves much greater use for streets, parking islands, and containers; may develop oval-rounded outline; used in Athens and has not proven satisfactory over a 20- to 25-year period as leaves discolor to sickly yellow-green in winter in exposed locations.

RATE: Slow.

TEXTURE: Medium-fine throughout the seasons.

BARK: Smooth, gray, beech-like, actually smoother than a beech even in maturity.

LEAF COLOR: New foliage emerges purple-bronze, and changes to lustrous medium green with maturity; in sunny, exposed locations discoloration may occur in winter months; persist for 2 years before falling; leaves emerge later than *Q. glauca* and potentially avoid late frost damage.

FRUIT: Acorn, 2 to 4 together, 1/2 to 1" long, oval-oblong, covered 1/3 to 1/2 by the glabrous cap which has 3 to 6 concentric rings, nut is brownish black, ripen in first year.

CULTURE: Transplant balled-and-burlapped before buds break in winter or early spring; unbelievable soil tolerance: sandy, clay, acid, alkaline or dry; withstands tremendous summer heat; full sun to partial shade.

DISEASES AND INSECTS: Sapsuckers can seriously injure trees; is probably the factor limiting use in some areas; am seeing "canker" on Dirr garden tree that is killing limbs; sapsuckers have wreaked havoc on this species in cultivated situations, however, I observe gigantic trees that have survived and prospered, an anomaly that I am unable to resolve.

LANDSCAPE VALUE: Superb small street or lawn tree, used in Greenville, SC to soften large office buildings, plants were in raised planters, beautiful throughout the seasons; trees at the old USDA Bamboo Station in Savannah were 30 to 40' high and withstood the test of time.

PROPAGATION: Collect seed in fall and sow immediately or store and provide 1 to 2 months cold moist stratification before spring planting. Have successfully rooted the species using June cuttings and 1.0% KIBA.

NATIVE HABITAT: Widely distributed in eastern Asia from Japan and Taiwan through China and the Himalayas. Introduced 1807.

RELATED SPECIES: Upon arrival in Georgia, I was introduced to several new evergreen oaks, although *Q. myrsinifolia* I had previously seen at the U.S. National Arboretum. Unfortunately, the nursery industry has confused *Q. acuta*, *Q. glauca*, and *Q. myrsinifolia* which are listed in various catalogs as unique entities but in general describe the same oak, *Q. glauca*. The differences are adequately described under each species but for quick reference remember that the leaves of *Q. acuta* are entire, those of *Q. glauca* usually coarsely toothed one-third to one-half from the base to the apex. Also, *Q. myrsinifolia* is the most cold hardy, *Q. acuta* will grow only in Zone 8, if there, and *Q. glauca* was killed to the ground in Zone 7 at -3°F . Relative to hardiness, Dr. Randy Johnson, formerly U.S. National Arboretum, told me of a *Q. acuta* that was cold hardy there. U.S. National has experienced at least -10°F in the coldest winters of the past 30 years.

***Quercus acuta* Thunb.** — Japanese Evergreen Oak
(kwēr'kus a-kū-ta)

LEAVES: Alternate, simple, evergreen, elliptic to ovate, 2 1/2 to 5 1/2" long, 1 to 2 1/4" wide, long acuminate, rounded to broad cuneate, entire, somewhat undulate, lustrous dark green above, yellowish green below, glabrous, 8 to 10 vein pairs; petiole—about 1" long.

Quercus acuta, Japanese Evergreen Oak, is essentially non-existent in the Southeast and the first place I have turned up a specimen was in the Botany herbarium and it listed the location as a park in Albany, GA. For some unknown reason, this species has been listed in nursery catalogs instead of *Q. glauca* and *Q. myrsinifolia*, which are the principal trees in commerce. In Europe, where I have seen the tree, it is always small and shrubby to 20' high and wide, the leaves are handsome and the new growth emerges a purplish brown. Acorns are clustered like *Q. myrsinifolia* and the concentric-ringed cap covers about 1/3 of the 3/4" long nut. Woodlanders, Aiken, SC had a rather handsome specimen on the outside of their property. Bark is smooth and gray not unlike that of beech. Certainly beautiful in foliage but doubtfully competitive with the myriad broadleaf evergreens in Zone 8 and 9. Japan, Taiwan, Korea. Introduced 1878. Zone 8 to 9.

***Quercus glauca* Thunb.** — Blue Japanese Oak, Ring-cupped Oak
(kwēr'kus glā'ka)

LEAVES: Alternate, simple, evergreen, oblong, elliptic, to obovate-oblong, 2 1/2 to 5 1/2" long, 1 to 2 1/2" wide, strongly acuminate, slenderly tapered to rounded, strongly serrate in upper 1/2 to 2/3's, leathery, lustrous dark green above, gray-green beneath, pubescent, with 8 to 12 vein pairs, prominent beneath; petiole—1/2 to 1" long, yellow.

BUDS: Imbricate, abundantly clustered (5 to 7) at ends of stem, conical-angular, 5-sided, 1/4 to 1/3" long, brown, glabrous, laterals diverge from stem at 45° angle.

STEM: Stout, slightly angular, dark olive-green, eventually becoming brown or purplish brown, glabrous, covered with small grayish lenticels; pith—solid, off-white.

FRUIT: Acorn, 1 to 3 in a cluster, 3/4" long, enclosed 1/3 in a downy cap with 6 to 7 raised concentric rings, ripens in one year.

Quercus glauca, Blue Japanese Oak, makes a handsome, almost shrubby appearance in the landscape. The habit is distinctly upright-oval with ultimate size approximately 20 to 30' and spread about one-half this. The overall appearance is quite formal and the plant is best utilized in groupings. New foliage is either a rich green or bronze to purple-green. Very handsome when the new foliage emerges which usually occurs in early April in the Piedmont. The emerging leaves may be injured by a late spring freeze. The leathery lustrous dark green leaves are handsome throughout the seasons. Tolerates heavy clay soils. Makes an excellent, large, screen plant and requires a minimum of maintenance. The 1983–84 winter (–3°F in Athens) devastated the species and fine old specimens in Athens–Atlanta were killed. Was used at Atlanta Historical Society as a large screen and was effective and functional. Cold rendered these plants rubble. Possibly the handsomest specimen in cultivation in the United States resided in Brookgreen Gardens, Murrells Inlet, SC. The tree is shaped like a giant mushroom, probably 30' high and 40' wide with low-slung, wide-spreading branches. Japan, Taiwan, Himalaya, China. Introduced 1804. Zone (7)8 to 9.

***Quercus phillyreoides* A. Gray — Ubame Oak**
(kwēr'kus fil-ē-rē-oy'dēz)

LEAVES: Alternate, simple, evergreen, oval to obovate, 1 1/4 to 2 1/2" long, at times almost as wide, acuminate to rounded, rounded to subcordate, entire on lower half, shallow dentate above, shining dark green, glabrous above, pale, shining and glabrous below; petiole—1/4" long, pubescent.

Quercus phillyreoides has been cold hardy at the JC Raulston Arboretum, Raleigh, NC where it forms an irregular, shrub-like habit. Landscape size approximates 15 to 25'. New growth emerges bronzy red. The leaves are quite handsome but beyond this has little to recommend it for everyday use. 'Emerald Sentinel' was introduced by JC Raulston Arboretum for its upright habit, fast growth (Raulston reported 5 to 6' per year), showy catkins, and ease of rooting. Plant does not inspire and has limited commercial use. China, Japan. Introduced 1861. Zone (6)7 to 8.

***Quercus salicina* Blume**, (kwēr'kus sal-is-ē'na), is closely related to *Q. glauca* but the lanceolate leaves are lustrous dark green above, silvery below with acorns ripening the second year. Leaves 2 to 4(6") long, 1 to 2" wide. The few trees I have seen were small, shrubby to 20'. Southern Japan, South Korea, cultivated 1895. Zone 8 to 9. Have read Zone 6 hardiness designation. Little in the better literature about this species.

***Quercus nigra* L. — Water Oak, also called Possum Oak**
(kwēr'kus nī'gra)

LEAVES: Alternate, simple, exceedingly variable as to size and shape, obovate, 3-lobed at apex or sometimes entire, rarely pinnately lobed above the middle, 1 1/2 to 4" long, 1/2 to 2" wide, dull bluish green to lustrous dark green above, paler beneath, soon glabrous except for axillary tufts of brown hairs; petiole—1/10 to 1/4" long.

BUDS: Imbricate, ovoid, pointed, prominently angled, smooth, brown, 1/8 to 1/4" long.

STEM: Slender, smooth, dull red to brown.

FRUIT: Acorn, usually solitary, 1/2" long and wide, enclosed 1/4 to 1/3 in a broad, shallow, short-stalked cap with appressed scales; nut with alternating striated bands of brown and black.

Quercus nigra is a conical to round-topped tree, 50 to 80' high. National champion is 118' by 108' in Jones County, MS. It is popular in the South and is common on the University of Georgia campus where 60 to 70' high specimens grow in the most inhospitable locations. Transplants readily and is quite adaptable on moist to wet sites. Typically, it is a bottomland species and is widespread and abundant along streams throughout the Southeast from the Coastal Plain to the foothills of the mountains. Has been used effectively as a shade and street tree. The leaves persist quite late into fall and winter and I have observed a modicum of green foliage on trees in Spring Grove, Cincinnati, OH, as late as December. The species is a weed tree in Zone 7 to 9 and can be found with Chinaberry in every abandoned location. In our garden, this is the most encountered oak and is a challenge to eliminate. The young juvenile seedling leaves are highly-lobed and often evergreen. They look *nothing* like the species. This condition may persist for 3 to 6 years. The tree is also more weak-wooded than most oaks and limbs will break in wind, snow and ice. The inherent soil tolerance makes the species worth considering. Read a paper, *Annals of Botany* 52:81-92 (1983), that reported seeds are difficult to germinate and require about 105 days of combined stratification and germination time for maximum germination; see also *Annals of Botany* 78:181-187 (1996). Water Oak extends from southern New Jersey, south to Florida, west to eastern Texas; and northward, in the Mississippi valley, to southeastern Missouri and eastern Oklahoma. Introduced 1723. Zone 6 to 9.

Quercus palustris Münchh. — Pin Oak, also called Swamp Oak

(kwēr'kus pa-lus'tris)

LEAVES: Alternate, simple, elliptic or elliptic-oblong, 3 to 6" long, at times almost as wide, terminal lobe long acuminate, cuneate at base, sometimes truncate, 5- to 7-lobed, lustrous dark green above, lighter green beneath with axillary tufts of hair; key feature—major lobes U-shaped in comparison with C-shaped lobes of *Q. coccinea*; petiole—up to 2" long, slender.

BUDS: Imbricate, conical to ovate, sharp-pointed, 1/8 to 1/4" long, gray-brown to chestnut brown.

STEM: First year stems slender, greenish to brown; second and third year often greenish.

SIZE: 60 to 70' in height with a spread of 25 to 40', can attain a height of over 100'; national champion is 135' by 97' in Bell, KY.

HARDINESS: Zone 4 to 8.

HABIT: Strongly pyramidal, usually with a central leader; the lower branches pendulous, the middle horizontal, and the upper upright; in old age the tree assumes an oval-pyramidal form and loses many of the lower branches; very distinctive tree because of growth habit and widely planted as a lawn and street tree for this reason.

RATE: One of the faster growing oaks, 12 to 15' over a 5 to 7 year period; 'Sovereign' averaged 2'5" per year over a 10 year period in Kansas tests.

TEXTURE: Medium in leaf, medium-coarse in winter.

BARK: Grayish brown, thinnish, smooth and with age develops narrow, relatively shallow ridges and furrows.

LEAF COLOR: Glossy dark green in summer changing to russet, bronze or red in fall; fall coloration is variable; great opportunity for selection if vegetative propagation techniques could be developed.

FRUIT: Nut, solitary or clustered, sessile to short-stalked, 1/2" high, 2/3 to 3/4" wide, nearly hemispherical, light brown, often striate, enclosed only at basal 1/4 to 1/3 in a thin, saucer-like cap, mature in second year.

CULTURE: Readily transplanted because of shallow, fibrous root system; will tolerate wet soils and is found in the wild on wet clay flats where water may stand for several weeks; actually prefers moist, rich, acid, well-drained soil; very intolerant of high pH soils and iron chlorosis can be a significant and disastrous problem with this species; somewhat tolerant of city conditions; tolerant of sulfur dioxide; full sun.

DISEASES AND INSECTS: Galls are often a problem; iron chlorosis can be serious but can be corrected; the use of capsules (ferric ammonium citrate) placed in the tree has proven very effective and has worked over a 3-year period. Sinex, *American Nurseryman* 173(7):78–80, 82 (1991), discusses “Pin Oak Malady” and efforts to cure chlorosis. She utilized the iron-nutrient capsules to improve the appearance of the Pin Oaks but agonized over long-term damage from implanting and physical damage. The best advice is avoid Pin Oak when the pH is too high.

LANDSCAPE VALUE: Probably the most widely used native oak for landscaping; a 1989 published survey by *American Nurseryman* magazine listed this as the most popular shade tree; possesses interesting habit and has been used for lawn, park, golf courses, commercial landscapes and streets; personally I feel there are many other superior oaks and tree species but this oak has outstanding customer appeal; correcting the chlorosis problem can be painful for the homeowner.

CULTIVARS:

‘Crownright’ (‘Crown Right’)—More upright habit, branches occur at a 30 to 60° angle to central leader and do not sweep ground; introduced by Princeton Nursery.

Green Pillar® (‘Emerald Pillar’, ‘Pringreen’, PP 9,093)—Columnar form that will prove a significant addition to contemporary landscapes if graft incompatibility does not rear its ugly head; leaves lustrous dark green, red foliage in autumn; quite columnar with extremely glossy foliage into late summer; I looked closely at the leaves at Schmidt’s in August, 2006 and thought there might be some Scarlet, *Q. coccinea*, in its bloodline; 50’ by 15’; the more I see the tree, the greater the enthusiasm; Princeton Nursery introduction.

Promenade® (‘QS20’)—Upright dense branching pattern; consistent yellow-orange fall color; relatively fast growth rate; based on my observations, an excellent tree; Select Trees introduction.

‘Sovereign’—The lower branches do not weep but are borne at a 90° to 45° angle to the main leader; former Cole Nursery Company introduction.

PROPAGATION: Seed, stratify at 32 to 41°F for 30 to 45 days; ‘Sovereign’ was originally grafted on Pin Oak seedlings; however, after several years a graft incompatibility resulted; this was supposedly solved by grafting onto seedlings which had been produced from nuts collected from the original ‘Sovereign’ tree; from what I understand the incompatibility problem still occurs and this cultivar is largely discontinued. Our early cutting propagation work indicated Pin Oak could be rooted, take cuttings when first growth flush hardens, 10,000 ppm KIBA, 2 perlite:1 peat, mist, with rooting 4 to 8 weeks later; see Drew and Dirr, *J. Environ. Hort.* 7:115–117 (1989); also Drew et al., *J. Environ. Hort.* 11:97–101 (1993). Another cutting paper discusses success with *Q. geminata*, *Q. hemisphaerica*, and *Q. nigra*, no success with *Q. laurifolia* and *Q. virginiana*. Rooting success coincided with 1st and 2nd flushes of growth and use of IBA and NAA; see *Proc. Florida State Hort. Soc.* 102:260–264 (1989).

NATIVE HABITAT: Massachusetts to Delaware, west to Wisconsin and Arkansas. Introduced before 1770.

RELATED SPECIES:

***Quercus coccinea* Münchh. — Scarlet Oak**

(kwēr’kus cok-sin’ē-a)

LEAVES: Alternate, simple, oblong or elliptic, 3 to 6” long, 2 1/2 to 4 1/2” wide, truncate or rarely broadly cuneate at base, with 7, rarely 9, bristle-tipped lobes, lustrous dark green above, shiny and glabrous beneath except tufts of hair sometimes occur in vein axils, major lobes C-shaped; petiole—1 1/2 to 2 1/2” long, glabrous, yellow.

BUDS: Imbricate, broadly ovate, blunt apex, 1/4 to 3/8” long, dark reddish brown and glabrous below, pale woolly pubescent above middle, bud is shaped like a rugby ball.

STEM: Light brown to red-brown, glabrous, dotted with small gray lenticels, angled, older stems green with a luster.

Quercus coccinea, Scarlet Oak, grows 70 to 75’ in height by 40 to 50’ in width under landscape conditions but can reach 100’ in the wild. On the Georgia campus 70 to 80’ high and wide trees have withstood the test of time. National champion is 119’ by 120’ in Oglethorpe, GA. Habit in youth is somewhat similar to Pin Oak but becomes more rounded and open at maturity. Will grow 1 1/2 to 2’ per year over a 10 to 20 year period. Foliage is an excellent glossy dark green in summer changing to scarlet in the fall, unfortunately, some trees color russet red, if at all. Color develops in mid-November in the Athens area. One of the last species to develop fall color before the snow flies. Leaves, particularly on young trees, persist dry into winter. Fruit is solitary or paired, short-stalked, 1/2 to 1” long and wide, oval to hemispherical, reddish

brown, rarely striate, often with concentric rings near the apex, 1/3 to 1/2 enclosed in a deep, bowl-like cap. Less tolerant of adverse conditions than Pin Oak and Red Oak and not as available in the nursery trade. Interestingly, more nurseries are now offering the species, although with difficulty in identification, it is tenuous to determine if true Scarlet Oak is being sold. Generally found on dry, sandy soils. Usually does not develop chlorosis problems to the degree of Pin Oak. Averaged 1'1" per year over 10 years in Kansas tests. 'Splendens' has rich scarlet fall color. Native range extends from Maine to Florida, west to Minnesota and Missouri. Zone 4 to 9. Introduced 1691.

Quercus ellipsoidalis E.J. Hill — Northern Pin Oak, Hill's Oak
(kwēr'kus ē-lip-soy-da'lis)

LEAVES: Alternate, simple, obovate or elliptic, 2 1/2 to 6" long, 2 to 4 1/2" wide, 5- to 7-lobed, truncate or cuneate, silky tomentose upon emergence, soon lustrous dark green, paler beneath with tufts of hair in vein axils; petiole—1 1/2 to 2" long.

Quercus ellipsoidalis, Northern Pin Oak, is a northern midwestern version of *Q. palustris* without the inherent chlorosis problems. The species is utilized in the Midwest. Will grow 50 to 60' high and mature specimens in the Morton Arboretum are over 80' high and wide. National champion is 92' by 80' in Portage, WI. Have grown small seedlings in Georgia and if they were not labeled as such, it would be difficult to separate from Pin and Scarlet (see leaf drawing). Leaves are lustrous dark green and may turn respectable red in autumn. Our seedlings did not, perhaps attributable more to Zone 7 environmental conditions than genetics. Acorn is 1/2 to 3/4" long, ellipsoidal to subglobose, covered 1/3 to 1/2 by cap, nut brownish with striate lines. Southern Michigan, to Manitoba and Iowa. Introduced 1902. Zones 4 to 6.

Quercus nuttallii Palmer (confusing taxonomy and is now considered *Q. texana* Buckley by GRIN; *Q. nuttallii* is the accepted name in the nursery trade) — Nuttall Oak
(kwēr'kus nū-tal'lē-ī)

LEAVES: Alternate, simple, much like *Q. shumardii*, deeply 5- to 9-lobed, with wide rounded sinuses and narrow lobes, 4 to 9" long, 2 to 5" wide, lustrous dark green above, paler beneath with tufts of hairs in axils of main veins.

BUDS: Imbricate, 1/8 to 1/4" long, ash gray to brown-gray, pubescent, scale margins ciliate.

STEM: Brownish gray, glabrous.

Quercus nuttallii, Nuttall Oak, was essentially an unknown landscape entity but is fast replacing *Q. palustris* and *Q. shumardii* in Zones (7)8 and 9 because of superior adaptability, rich reddish purple new growth, reddish fall color, rapid growth and clean leaf drop (not always) in autumn. Acorns are 3/4 to 1 1/4" long, ovoid-oblong and covered 1/3 to 1/2 by the cap. Received a nifty lesson in acorn cap differences between

Quercus ellipsoidalis*Quercus nuttallii*

Q. nuttallii and *Q. shumardii* from Mr. Charles Webb, Superior Trees, in December 2008. In brief, *Q. nuttallii* has a turbinate (more bumpy scales) cap that covers more of the nut while *Q. shumardii* is a broader, shallower cap with scales gently overlapping. I witnessed the above characteristics and they were genuine. The species is considered a southern version of *Q. palustris* and *Q. shumardii* by most taxonomists and is found in floodplains, bottomlands and river terraces. Landscape size will approximate 40 to 60' high. National champion is 113' by 81' in Vernon, LA. The better reference books cite similarities to *Q. coccinea*, *Q. palustris*, and *Q. shumardii*. Plants I have observed favor *Q. shumardii*. A 1991 article in *Nursery Manager* 7(10):14 presented an overview of grower thoughts about the species. I have summarized them here: does not stop growing in summer when it's hot like Shumard (Texas); grows faster, calipers quicker, doesn't fork (central leader); withstands greater diversity of pH; tolerates wet soils and early summer digging (Louisiana); develops a fuller canopy (head) at an early age. Highpoint® ('QNFTA', PP 13,524) offers dense habit and consistent yellow-orange-red fall color and ease of cutting propagation; discovered by Tommy Strickland, assigned to Tree Introductions, Inc., Athens, GA. Select Trees, Athens, GA has introduced the following own-root cultivars: Arcade® ('QNST6') with upright branching habit, consistent red new foliage growth with each flush, fall color varies from orange-red to yellow-orange; Esplanade® ('QNSTC', PP 16,401) has a slightly upright branching habit, dense canopy, consistent red fall color in Athens and is fast growing; and Sangria® ('QNSTD', PP 16,254) has a dense canopy, rounded branching habit, consistent deep red new foliage with each growth flush, dark green summer foliage, and yellow-orange to orange-red fall color. Western Alabama to east Texas and Oklahoma, north to southeastern Missouri and southern Illinois. Introduced 1923. Zone (5)6 to 9.

***Quercus shumardii* Buckl. — Shumard Oak, Swamp Red Oak**
(kwēr'kus shū-mar'dē-ī)

LEAVES: Alternate, simple, obovate to elliptic, 4 to 6"(8") long, 3 to 4" wide, usually with 7 lobes, occasionally 9, sinuses cut deeply to midrib, leathery, lustrous dark green above, glabrous except for axillary tufts of hairs below; petiole—1 1/2 to 2 1/4" long.

BUDS: Probably the only reliable aid to separate this species from *Q. palustris* and *Q. coccinea*; imbricate, angle-ovoid, 1/4 to 3/8" long, glabrous, gray- or pale straw-colored, never reddish brown, scales appear waxed and often difficult to see the imbricate nature of the scales.

STEM: Gray-brown, glabrous, not as shiny as Pin Oak; older stems greenish brown with onion-like sheathing of epidermis.

Quercus shumardii, Shumard Oak, is a pyramidal tree becoming more spreading, much like Scarlet Oak, at maturity. Will grow 40 to 60' and wide at landscape maturity but can reach 100' or more in nature. National champion is 96' by 96' in Anna, IL. Leaves may turn a good russet-red to red in fall. Most of my observations reflect yellow-bronze to slight reddish fall coloration. Many trees on the Georgia campus and none develop outstanding reds. Acorns are ovate, 3/4 to 1" (1 1/2") long, short-stalked and covered only at the base by a broad, shallow involucre cap. See my comment under *Q. nuttallii* about cap distinctions. Nut is striated with brown-black lines. Is relatively easy to transplant as I have seen no obvious transplant-related mortality in landscape settings. Considered a drought tolerant species and plantspeople in Florida, Oklahoma and Texas have extolled its virtues for use in those areas. Work in Mississippi showed that *Q. shumardii* had good survival and growth in three plantations, 10-, 11- and 25-years-old, on pH 7.8 to 8.0 alluvial soils along the Mississippi River. Interestingly, in the wild, is found along streams, near swamps, or bodies of water in well-drained soil. Grew 1'3.4" per year over a 10 year period in Kansas tests. Proved superior in 13 year shade tree evaluations at Auburn University. 'Armistad' is listed as an evergreen form by Louisiana Nursery. Madison™ ('ACNRT1', PP 15,226) is a more fastigiated, narrow-oval, own-root cultivar; parent tree with dark green foliage, tight branching and dense canopy; 60' by 20'; Angel Creek Nursery introduction, Bishop, GA. Panache® ('QSFTC', PP 14,424) has glossy dark green foliage, consistent orange-red fall color in Athens, GA and uniform branching pattern; own-root, Select Trees introduction. Prominence® ('QSSTH') produces ascending branches with a dense canopy, consistent red fall foliage in Athens, GA, fast growing compared to seedling Shumards; own-root, Select Trees introduction. Kansas to southern Michigan to North Carolina, Florida and Texas. Also known in 4 counties in southwestern Ontario. Introduced 1907. Zone 5 to 9.

Quercus phellos L. — Willow Oak

(kwēr'kus fel'ōs)

LEAVES: Alternate, simple, narrowly elliptical or lance-shaped, 2 to 5 1/2" long, 1/3 to 1" wide, acute, slightly wavy and entire on margins, tipped with a bristle, medium to dark green, glabrous above, undersurface glabrous or hairy along midrib; petiole—1/8 to 1/4" long.

BUDS: Imbricate, 1/8 to 1/4" long, ovoid, sharp-pointed, chestnut brown.

STEM: Slender, smooth, somewhat lustrous, reddish brown to dark brown.

BARK: Older, becoming gray and roughened by irregular furrows and thick, more or less scaly ridges.

SIZE: 40 to 60' high, 30 to 40' wide to a comparable spread, can grow 90 to 100' in ideal situations; national champion is 131' by 130' in Chesapeake, VA.

HARDINESS: 5 to 9, I still remember a handsome specimen on The Ohio State University Campus as well as older trees in Cincinnati that have been through -25°F; growing on Cape Cod, at the Public Garden in Boston, and in Newport, RI; well adapted to the Southeast and among the most widely planted of all oaks.

HABIT: Pyramidal in youth, developing a dense oblong-oval to rounded crown at maturity.

RATE: Medium, 1 to 2' per year, may average 2' per year over a 10 to 20 year period, difficult tree to train to a central leader and requires considerable pruning in early years to make a respectable crown.

TEXTURE: Medium-fine through the seasons.

BARK: On old trunks, lightly ridged-and-furrowed, gray-brown.

LEAF COLOR: Light to bright green in spring, dark green in summer, changing to yellow, bronze-orange, yellow-brown and russet-red in fall.

FRUIT: Acorn, solitary or paired, 1/2" or less long and wide, subglobose, more or less stellate pubescent, enclosed at the base by a thin saucer-like cap, striated with alternating brown and blackish bands, maturing in second year.

CULTURE: Transplants more readily than most *Quercus* species because of more fibrous root system, should still be moved in dormant season, preferably during winter, prefers moist and well-drained soil but can

adapt to virtually impossible habitats, many nurseries root prune the species to insure transplanting success.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: From Zone 6 to 9, still the best oak for overall texture and form; finer textured than most and makes a splendid avenue, street or boulevard tree, also excellent for large area use, i.e., commercial establishments, golf courses and parks; many years past Milliken Corporation planted either side of I-85 (now Business 85) in Spartanburg, SC and the effect is outstanding; I have mentioned the planting to people and they immediately remember driving by the trees; this is the *best* landscape oak for Zone 6 to 8, almost guaranteed to succeed and thrive; new leaves (early April) emerge hazy yellow-bronze before maturing dark green; overall texture is the finest of the common landscape oaks; great old trees line Franklin Street in Chapel Hill, NC.

CULTIVARS:

Ascendor® ('QPSTJ')—Dominant central leader with upswept branches and dense canopy; yellow fall color; relatively fast rate of growth; Select Trees introduction.

Hightower® ('QPSTA', PP 13,677)—Beautiful lustrous dark green leaves with good mite resistance, central leader, uniform pyramidal outline; selected from seedling Willow Oaks in the summer of 1990 by Mike Glenn and myself; dry, hot summer and mites were abundant yet this tree was clean.

'Pillow Oak' ('Palmetto', PP 12,145)—An illegitimate name but one coined by Mr. Ray Bracken, Piedmont, SC to describe a suspected Pin/Willow hybrid; Ray discovered the plant in a seedling block of *Q. palustris* and noticed the rapid growth and different leaf shape; also it has been extremely easy to root from cuttings and overwinter; I worked with Ray in the early days on rooting protocol and he has grown trees to landscape size; this hybrid is listed as *Q. xschochiana* Dieck and a plant at Hillier was uniformly branched and cleanly dropped its leaves; we maintained trees for about 10 years in our Georgia tests and were always able to root them with ease.

Shiraz® ('QPSTB', PP 18,321)—Dense canopy, dominant central leader; consistent deep red fall color in Athens GA; relatively fast growing; Select Trees introduction.

Upperton™ ('RT3', PP 16,444)—An upright-pyramidal form with dense branching and dark green foliage, leaves longer than typical willow oak; 55' by 15', own-root propagation; introduced by Ray Tate, GA.

Wynstar® ('QPMTF', PP 15,217)—Uniform habit; dark green leaves, russet-orange in fall; improved spider mite resistance; 70 to 80' by 40 to 50'; Zone 6 to 9; own-root propagation; introduced by Moon's Tree Farm, Loganville, GA.

PROPAGATION: Stratify seed in moist sand or peat for 30 to 60 days at 40°F or directly sow outside and germination will take place in the spring. Mr. John Drew, a former graduate student, conducted interesting work on rooting *Quercus* species from cuttings. *Quercus phellos* was one of the easiest to root. He used firm cuttings after the first flush of growth hardened, 10,000 ppm KIBA-quick dip, 2 perlite:1 peat, mist, with 60 to 80% rooting in 10 weeks on *Q. phellos*, *Q. robur*, and *Q. lyrata*.

NATIVE HABITAT: Bottomlands, floodplains and adjacent slopes, rich uplands from New York to Florida, west to Missouri, Oklahoma and Texas. Introduced 1723.

Quercus robur L. — English Oak, Truffle Oak, Pedunculate Oak

(kwēr'kus rō'bēr)

LEAVES: Alternate, simple, obovate to obovate-oblong, 2 to 5" long, 3/4 to 2 1/2" wide, apex rounded, auriculate to rounded base, 3 to 7 vein pairs of rounded lobes, glabrous, dark green to dark almost blue-green above, pale bluish green beneath; key feature, earlobe-like leaf base (auriculate); petiole—1/6 to 1/3" long.

BUDS: Imbricate, rounded, plump, angled, 1/4 to 3/8" long, chestnut to reddish brown, scales fringed with hairs.

STEM: Glabrous, reddish brown, often purplish, angled, similar to White Oak.

SIZE: The species can reach 75 to 100' or more in height with a comparable spread; in the United States averages 40 to 60' under landscape conditions; national champion is 108' by 103' in Olympia, WA.

HARDINESS: Zone 4 to 8.

HABIT: Large, massive, broadly rounded, open-headed tree with a short trunk; too large for the average landscape; in youth pyramidal to rounded; have seen magnificent specimens in England.

RATE: Slow to medium, averaged 1'4" per year over a 10-year period in Kansas tests.

TEXTURE: Medium in leaf, probably would be considered coarse in winter.

BARK: Deeply furrowed, grayish black.

LEAF COLOR: Dark green to blue-green in summer; fall color is nil for the leaves either abscise green or persist and change to a nondescript brown.

FRUIT: Acorn, about 1" long, narrow elongated-conical, enclosed 1/3 to 1/2 by the cap, one or several on a slender 1 to 4" long peduncle, nut shiny brown, ripen the first year.

CULTURE: Transplant balled-and-burlapped; prefers well-drained soil; pH tolerant; full sun.

DISEASES AND INSECTS: Mildew is often a serious problem on the species and 'Fastigiata'.

LANDSCAPE VALUE: The species is widely used in Europe; good tree for parks and other large areas; too many better native oaks to justify extreme excitement over this introduced species although 'Fastigiata' (named clones) is a fine selection; does reasonably well in Zone 7 but cannot measure up to *Q. phellos*, *Q. lyrata*, and others; Dr. Dale Herman, North Dakota State University, mentioned that he had a good selection hardy to at least -35°F ; also, I have observed a number of fastigiate hybrids involving 'Fastigiata' and *Q. alba*, *Q. bicolor*, *Q. montana* and other species as parents; these hybrids are more mildew resistant and appear better suited to cultivation particularly in the plains states and Midwest; Earl Cully, Jacksonville, IL introduced several worthy hybrid selections that are listed under CULTIVARS.

CULTIVARS: Many selections are reported in the literature, most relegated to minor status. See *J. Arboriculture* 11(10):307–315 (1985) for the American checklist of *Q. robur* cultivars. Counted 117 valid cultivars tagged to this species. The following are forms that I have observed and/or new introductions.

'Atropurpurea'—This plant has jumped in my path many times in European gardens; the color is more brown-red than reddish purple and fades with time, leaves are slightly smaller than typical and the growth rate is slower; tree will probably mature between 20' and 30'(40') high and wide; I am often confused by 'Purpurascens' (f. *purpurascens* (DC.) A. DC.) which supposedly has young leaves and stems reddish becoming green (almost) with maturity.

'Attention'—Superior tight columnar growth form, does not broaden with age; dark green foliage exhibits mildew resistance; 60 to 80' by 15'; Zone 5 to 8; a Wandell introduction, selection from 'Fastigiata'; John Barbour, Bold Spring Nursery, Monroe, GA witnessed slight mildew susceptibility but this selection was much more resistant than typical 'Fastigiata' seedlings.

'Concordia'—Leaves are bright yellow when they first appear in the spring; should be sited in partial shade as the leaves will sun-scorch; there is a 25 to 30' high specimen in Spring Grove which is rather striking when the leaves first emerge; leaves fade to green in summer; in fact, I tried to find the tree in summer and it looked so much like the species I was not sure if I had the real thing; old cultivar before 1843; great, old, 35 to 40' tree at Wilton House near Salisbury, England.

Crimson Spire™ ('Crimschmidt', PP 9,103)—Columnar, tight-fastigiate, 45' by 15'; dark green to blue-green leaves, rusty-red in fall, mildew resistant; *Q. alba* × *Q. robur* 'Fastigiata'; slightly wider/more bulbous at base than Regal Prince®.

'Cristata'—Small leaves clustered together and crinkled; observed on several occasions, best in the collector's garden.

'Fastigiata' (f. *fastigiata* (Lam.) O. Schwarz)—Distinctly upright and columnar in habit, however, variation occurs because the cultivar is often grown from seed; it comes 80 to 90% true; a mature tree may be 50 to 60' in height but only 10 to 15' wide, also listed as var. *fastigiata* (Lam.) A. DC.; since it has been grown from seed various selections have been made; this is a beautiful tree and along with the Fastigiate European Beech should be more widely grown; definitely could use good mildew-free clones; as discussed earlier, hybrids between this and other oak species hold great promise for the future; counted 20 selections of 'Fastigiata' in McArdle and Santamour's *J. Arboriculture* checklist; now the upright types are umbrellaed by the Fastigiata Group with 'Fastigiata Koster' designating the tree of narrow, columnar habit; the latter is offered by several U.S. nurseries; 'Fastigiata Purpurea' has reddish purple young leaves, slower growing than 'Fastigiata Koster'.

- 'Filicifolia'—In the 1983 edition, I reported this as 'Asplenifolia' as it was labeled at a particular arboretum, unfortunately, the name is correctly 'Filicifolia', a form with deeply cut sinuses and linear lobes that curve toward the apex creating a rather frond-like, fern appearance; the tree was small, pyramidal-rounded and is probably not greatly vigorous but was indeed attractive; 'Pectinata' belongs here.
- Heritage® ('Clemons', PP 11,413)—Selected from a row of F2 hybrid seedlings for its outstanding vigor and superior form, maintains central leader and develops a dense, uniform pyramidal crown; leathery, glossy dark green, tatter-resistant foliage, highly resistant to mildew; with age develops broad-rounded crown; 50' by 40'; Earl Cully introduction, *Q. robur* × *Q. macrocarpa* = *Q. ×macdanielii*.
- Kindred Spirit® ('Nadler', PP 17,604)—Beautiful upright-slightly pyramidal but more columnar selection that I have only observed in winter, but have seen photos of the tree in leaf; really sensational habit, parent tree was 35' by 7', glossy dark green leaves, highly resistant to mildew, withstood −28°F; introduced by Earl Cully, Heritage® Trees, Inc, Jacksonville, IL; hybrid of *Q. robur* 'Fastigiata' × *Q. bicolor*, *Q. ×warei* the hybrid epithet.
- 'Pendula'—Actually a handsome form of vigorous constitution with long growing shoots and widely arching weeping branches; have seen in Trompenburg Arboretum, Rotterdam, trained over a metal frame creating a vegetatively domed coliseum; worth seeking out, at least for the specialist; old cultivar possibly originated around 1816; reproduces from seed and multiple weeping clones are probably in commerce.
- Prairie Stature™ ('Midwest')—Broad pyramidal habit, densely foliated; dark green summer leaves turn red in autumn; hybrid of English and white oak, *Q. ×bimondorum*; Dr. Dale Herman, NDSU introduction.
- Regal Prince® ('Long', PP 12,673)—Strong, upright oval silhouette similar to 'Bowhall' Red Maple; bold dark green leaves, somewhat glossy on upper surface, glaucous on lower surface, highly resistant to powdery mildew, borers, wind, ice and low temperatures; this is one of the best upright oaks; has performed magnificently at Milliken Arboretum, Spartanburg, SC, foliage extremely clean, habit tight-columnar after about 18 years; Earl Cully introduction, *Q. robur* 'Fastigiata' × *Q. bicolor*.
- Rosehill® ('Asjes', PP 6,539)—Mildew-free selection, leaf color different than typical with glossy pure green rather than dull blue-green that is typical for species; is not as tight as typical 'Fastigiata'; looks like a hybrid with *Q. bicolor* but the acorns are typical *Q. robur*; has been mildew-free in the Southeast where disease pressure is terrific on typical English oaks; tends to have splaying branches and does not have a uniform, oval-fastigiate habit.
- 'Salicifolia'—Small, more compact, 20 to 30' high, pyramidal-rounded form with entire, elliptic, dark green leaves; a plant at Spring Grove, Cincinnati, had me guessing for a long time; a novelty to be sure but another reflection of species' variability.
- Skymaster® ('Pyramich', PP 3,707)—Narrow when young, becoming pyramidal, strong central leader and excellent lateral branch development, branches diverge at wide crotch angles; dark green leaves; of the three Schmidt introductions this was by far the worst for foliage wear and tear in the Southeast; 50' by 25'; Schmidt Nursery introduction, see Spongberg, *AABGA Bull.* 15(3):67–70 (1981).
- Skyrocket® ('Fastigiata')—A uniform, narrow, dark green-foliaged form with yellow-brown fall color, will grow 45' by 15'; the most impressive of the three Schmidt introductions for southeastern conditions; leafs out early with leaves almost full size on March 30, 1997 in Oconee County, GA, the other two with buds only swelling; foliage highly mildew resistant; branches tight and columnar on 2-year-old trees; definitely tighter than typical 'Fastigiata'; a 1989 Schmidt introduction; witnessed 45' by 15 to 20' tree in Schmidt Arboretum, August 19, 2008.
- 'Tabor' (PPAF)—Oval rounded habit; dark green summer foliage, pumpkin-orange fall color with red along the veins; survived −28°F; *Q. robur* × *Q. alba*, selected from seedlings in 1971; Heritage® Trees, Inc. introduction.
- Triple Crown® ('Taylor', PPAF)—A beautiful oval to rounded outline, fully clothed with lustrous dark green leaves; highly resistant to powdery mildew; hybrid between *Q. robur*, *Q. muehlenbergii* and *Q. macrocarpa*; Heritage® Trees, Inc. introduction; selected in 1975 from several thousand seedlings; withstood −28°F.
- Walkenbach™ ('Adeline', PPAF)—Upright, tight pyramidal form; in winter silhouette, reminiscent of Armstrong Red Maple but secondary branches stiffer, coarser; leaves leathery lustrous dark green with marginal scalloped teeth; highly resistant to powdery mildew; hybrid of *Q. robur* 'Fastigiata' and *Q. bicolor* (*Q. ×warei* the hybrid epithet); introduced by Mike and Scott Rood, Pea Ridge Forest, Hermann, MO.
- Westminster Globe® ('Michround', PP 3,708)—A broad-spreading, round-headed, symmetrical form with sturdy branch development, dark green leaves, some mildew and leaf distress; foliage not as healthy, clean as Skymaster™ at Milliken, May 20, 2007; probably, like Skymaster®, better suited in more northern climates; 45' by 45'; Schmidt Nursery introduction.
- There are variegated and other cut-leaf forms but none are particularly outstanding. Most white-variegated forms are rather weak growers and tend to produce reversion shoots. 'Argenteomarginata' (f. *variegata*, 'Variegata') is growing rather contentedly at the Raulston Arboretum. Amazingly, 55 variegated genotypes of *Q. robur* and *Q. petraea* were planted in Lisicine Arboretum, Zagreb, Croatia; see *Acta Horticulturae*

320:21–24 (1992). I visited a garden where the curator was proudly showing me a weeping White Oak. I took one look and saw the auriculate leaf base and quietly explained that he had a weeping English Oak.

Sometimes it pays to learn these subtle identification characteristics.

PROPAGATION: Seed requires no pretreatment. Cultivars are grafted onto seedling understock.

NATIVE HABITAT: Europe, northern Africa, western Asia. Long cultivated.

RELATED SPECIES:

Quercus frainetto Ten. (kwēr'kus fran-et'ō), Hungarian Oak, Italian Oak, is a large, 60 to 80' high and wide, boldly branched tree with large, heavily lobed, leathery dark green leaves, to 9" by 5". Have seen at Spring Grove where leaf spot had rendered it miserable. At Anglesey Abbey near Cambridge England, magnificent trees were in evidence. Forest Green® ('Schmidt') has excellent foliage and was introduced by Schmidt Nursery about 1989. Grows 50' by 30', glossy deep green leaves, yellow-brown fall color, Zone 5. 'Hungarian Crown', 'Trotworth' and 'Trump' are listed in RHS Plant Finder 2007–2008. Balkans, southern Italy. Cultivated 1838. Zone 5 to 7?

Quercus petraea (Mattusch.) Liebl. — Durmast Oak
(kwēr'kus pe-trē'a),

LEAVES: Alternate, simple, ovate to obovate, 3 to 5" (7") long, 1 to 3 3/4" wide, short- and round-lobed, truncate, broadly cuneate to attenuate, glossy dark green, almost blue-green above; petiole—3/8 to 3/4" long, yellow.

Quercus petraea, Durmast Oak, Sessile Oak, is similar to and hybridizes with *Q. robur*. It differs in the comparatively long-stalked leaves, nearly stalkless acorns, and lack of an auriculate leaf base. The hybrid (*Q. robur* × *Q. petraea*) is listed as *Q. xrosacea* Bechst. 'Columna', of fastigiate habit, like the Fastigate English Oak, is often confused with it but differs by the characteristics enumerated. Also, it is resistant to powdery mildew. Leaves are more sparse and it is not as handsome as the better *Q. robur* 'Fastigiata'. The species is a beautiful tree of rounded outline with bold, rugged branches. The most memorable tree for me, and the first truly large specimen I had observed, resided by the lake in front of the Palm House at Kew. I pulled a limb down to identify the tree and the sessile acorns spoke loudly—*Q. petraea*. 'Acutiloba', 'Laciniata Crispa', 'Mespilifolia', and 'Purpurea' are described but rarely seen in cultivation. Europe, western Asia. Long cultivated. Zone 4 to 7.

Quercus rubra L. — Red Oak, Northern Red Oak

(kwēr'kus rū'bra)

LEAVES: Alternate, simple, oval or obovate, 4 1/2 to 8 1/2" long, 4 to 6" wide, 7- to 11-lobed, cuneate, sometimes rounded, lustrous dark green above, grayish or whitish or sometimes pale yellow-green beneath with axillary tufts of brownish hairs; petiole—1 to 2" long, yellowish, glabrous.

BUDS: Imbricate, oval to ovate, 1/4 to 1/3" long, grayish at tip grading to brown at base, chestnut to reddish brown, sharp-pointed, smooth or with rusty hairs at extreme apex; scale margin slightly hairy.

STEM: Stout, greenish to reddish brown, glabrous.

BARK: With distinct flat gray areas intermingled with ridged-and-furrowed areas.

SIZE: 60 to 75' in height with a spread of 60 to 75', although can grow to over 100' in the wild; national champion is 80' by 102' in Monroe County, NY.

HARDINESS: Zone 3 to 7(8).

HABIT: Rounded in youth, in old age often round-topped and symmetrical.

RATE: Another oak of fast growth, many individuals relegate the oaks to slow status; however, there are significant exceptions; Red Oak can grow 2' per year over a 10-year period in moist, well-drained soil; however, in Wichita, KS tests averaged 11.5" per year over a 9-year period.

TEXTURE: Medium in leaf and winter.

BARK: On old trunks brown to nearly black and broken up into wide, flat-topped, gray ridges, separated by shallow fissures; on very old trees often deeply ridged-and-furrowed.

LEAF COLOR: Pinkish to reddish when unfolding, lustrous dark green in summer changing to russet-red to bright red in fall; sometimes disappointing and never passing much beyond yellow-brown.

FRUIT: Nut, solitary or paired, 3/4 to 1" long, variable in shape, but usually subglobose, enclosed at the base in a flat, thick, saucer-like cap, acorns mature and fall early, nut is medium brown with grayish streaks (hairs or wax?), mature in two years.

CULTURE: Transplants readily because of negligible taproot; prefers sandy loam soils which are well-drained and on the acid side; withstands the polluted air of cities; full sun; good performer although not as widely planted as Pin Oak; will develop chlorosis in high pH soils.

DISEASES AND INSECTS: The problems listed under White Oak are limitedly applicable to this species; *Xylella* can be serious.

LANDSCAPE VALUE: Valuable fast-growing oak for lawns, parks, golf courses and commercial areas; has been used as a street tree; excellent tree when properly grown; common street and urban tree throughout Midwest and East; on US-1 in Boston from Route 9 to Dedham, the trees line the street, amazing how well the plants have performed; not as well-adapted to Zone 7(8) because of heat and drought and although planted on the Georgia campus, it never attains the sizes that are common in the North; abundant in Maine and grows down to saltwater's edge; great old trees in Acadia National Park.

CULTIVAR:

'Aurea'—A form with new leaves of a clear yellow to golden yellow; I have doubts about its success in intense summer heat in the United States; have seen it at Kew Gardens where it provides a golden glow during spring, supposedly comes partially true-to-type from seed; also a large plant at Hillier, the new leaves vibrant yellow; Hillier, 2002, listed 'Limelight' as a yellow leaf form that does not scorch in full sun.

'Magic Fire', 'Boites Gold' and 'Sunshine' are described.

PROPAGATION: Seed requires 30 to 45 days at 41°F.

ADDITIONAL NOTES: Oaks hybridize freely and there are abundant hybrids evident in landscapes and the wild. Red and Black Oak are associated in the wild and hybrids frequently occur. The species is all over the coast of Maine, growing in rock and hardscrabble soil down to water's edge. Suspect there is a measure of salt tolerance.

NATIVE HABITAT: Nova Scotia to Pennsylvania, west to Minnesota and Iowa. Introduced 1800.

RELATED SPECIES:

***Quercus velutina* Lam. — Black Oak**
(kwēr'kus ve-lū'ti-na),

LEAVES: Alternate, simple, oblong-ovate to obovate, 4 to 10" long, 1/2 to 2/3's as wide, cuneate to truncate, 7 to 9 lobes, lustrous dark green above, glabrous below except in axils of veins; petiole—1 to 2 1/2" long.

BUDS: Imbricate, ovate to conical, 1/4 to 1/2" long, narrowed to a sharp point, generally 5-sided, strongly angled, covered with pale yellowish gray to dirty gray pubescence.

STEM: Stout, reddish brown or reddish, mottled with gray, tasting bitter if chewed and coloring saliva yellowish, downy when young, finally glabrous.

Quercus velutina, Black Oak, reaches 50 to 60' in height and the spread is variable, for the crown is often quite irregular and can be narrow or wide-spreading, elongated or

rounded. National champion is 80' by 100' in East Granby, CT. Extensive tap root and for this reason is somewhat difficult to transplant. Makes best growth on moist, rich, well-drained, acid soils but is often found on poor, dry, sandy, or heavy clay hillsides. Not an important tree in commerce. Fruit is solitary or paired, 1/2 to 3/4" long, ovoid to hemispherical, often striate, light red-brown, 1/3 to 1/2 enclosed in a deep, bowl-like cap. Bark is nearly black on old trunks, deeply furrowed vertically, and with many horizontal breaks; inner bark bright orange or yellow. Several 30 to 40' high trees on the Georgia campus that have prospered under the stresses of the southeastern summers. Keep encountering this species in Georgia. Almost easier to identify in winter because of buds. Hillier, 2002, describes 'Rubrifolia' with enormous leaves and yellow- to red-brown fall color. Native from Maine to Florida, west to Minnesota and Texas. Introduced 1800. Zone 3 to 9.

Quercus stellata Wang. — Post Oak

(kwēr'kus stel-lā'ta)

LEAVES: Alternate, simple, obovate, lyrate-pinnatifid, 4 to 8" long, 3 to 4" wide, cuneate at base, rarely rounded, with 2 to 3 broad, obtuse lobe pairs, the middle pair much larger and mostly with a lobe on the lower margin, separated from the lower lobes by wide, from the upper by narrow, sinuses, lustrous dark green and rough above, with grayish to brownish, rarely white tomentum beneath, finally glabrescent; petiole—1/2 to 1" long, pubescent; entire leaf has a cruciform appearance.

BUDS: Imbricate, subglobose to broadly ovoid, 1/8 to 1/4" long, reddish brown, pubescent or glabrous.

STEM: Stout, dirty gray-brown, tomentose, dotted with numerous lenticels.

Quercus stellata is seldom used in landscape situations but is frequently encountered in the wild throughout the southern states. Open-grown trees have a dense, round-topped crown with stout, spreading branches. Bark somewhat White Oak-like, gray to brown, flat ridges, somewhat scaly, eventually ridged and furrowed. Average height is 40 to 50'. In Georgia, 60 to 70' high trees are common. Co-national champions are 105' by 95' DeSoto, MS and 83' by 102' in Jackson, GA. Fall color has, on occasion, been reasonable golden brown. Most often the color is so nondescript that no one notices. The sessile nuts appear singly or in pairs, are egg-shaped, 3/4 to 1" long and are covered about 1/3 to 1/2 by the top-shaped cap, the scales of which are pointed, downy and appressed. It is typically found on dry, gravelly or sandy soils and rocky ridges. In the lower Mississippi Valley, on silty loam soils, it attains its greatest size. *Quercus margarettae* (Ashe) Small (var. *margarettae* (Ashe) Sarg.), Sand Post Oak, is common in the Coastal Plain from Virginia to Texas and is a small, scrubby tree. National champion is 86' by 97' in Jackson Co., FL. The lobes of the smaller leaves are more rounded and less cruciform than those of the species. Developed a fondness

for the species because of great foliage and picturesque growth habit. Trees become artistic, sculptural entities in old age. Have seen beautiful, round-headed tree on Martha's Vineyard to wind-sculpted, prairie-mediated, smallish trees in Oklahoma. Native from southern Massachusetts to Florida, west to Iowa and Texas. Introduced 1819. Zone 5 to 9.

Quercus virginiana Mill. — Live Oak

(kwēr'kus vēr-jin-ē-ā'na)

LEAVES: Alternate, simple, evergreen, elliptic-ovate, 1 1/4 to 3"(5") long, 3/8 to 1"(1 1/2") wide, entire or spiny, young seedling trees have holly-like leaves, revolute, leathery, lustrous dark green above, glabrous, gray-green beneath, woolly pubescent, prominent yellowish brown midrib; petiole—1/4" long, pubescent.

BUDS: Imbricate, slightly dome-shaped, reddish brown, glabrous or pubescent, 1/16 to 1/4" long.

STEM: Slender, terete, gray, glabrous or pubescent toward tip.

SIZE: Massive, ranging from 40 to 80' high and 60 to 100' wide; national champion is 77' by 155' in Ware, GA.

HARDINESS: Zone (7)8 to 10.

HABIT: Massive, picturesque, wide-spreading, evergreen tree with magnificent horizontal and arching branches that form a broad-rounded canopy; a single tree constitutes a garden; often imbued with Spanish moss which provides a mystical quality.

RATE: Moderate; slows down with age but in youth will respond to good fertility practices and produce 2 to 2 1/2' of growth per year.

TEXTURE: Medium.

BARK: On old trees becomes exceedingly dark, almost black, and develops a blocky characteristic in the mold of an alligator hide.

LEAF COLOR: New spring growth is a bright olive green that matures to lustrous dark green; old leaves all drop in the spring.

FLOWERS: Typical oak; females 1 to 5 together in axils of leaves; male in catkins.

FRUIT: 1 to 5 on a common stalk, but I have only seen one per 1/2 to 3"(5") long stalk on campus trees, 3/4 to 1" long, 1/3 enclosed by an ellipsoidal cap, nut dark brown to black, mature in single season.

CULTURE: Transplant in small sizes; adapts to about any soil type and is found in its native haunts in sandhills and extremely moist soils; tolerant of compacted soils and has been used with great success as a street tree throughout the South; nursery trees need to be pruned to develop suitable leaders; tolerant of salt spray.

DISEASES AND INSECTS: A gall insect that is more unsightly than anything else and a root rot in the coastal areas; oak wilt reported in Texas, see *J. Arboriculture* 20:250–258 (1994); also bacterial leaf scorch reported, see *Plant Disease* 78:924 (1994).

LANDSCAPE VALUE: Magnificent shade and mansion tree, not for the small property; used extensively for street tree plantings in the South; Savannah and Thomasville, GA have notable plantings; makes a great park, golf course and campus tree; have seen beautiful specimens on the Louisiana State University campus; at the University of Georgia, trees do not make the growth they do further south, this is due in part to the colder temperatures.

CULTIVARS: Wonderful possibilities for selection particularly for central leader, dense foliage, and ease of production. Travel to southern cities and witness the almost monoculture of the species and the potential economics and practicalities of cultivars become manifest.

Boardwalk® ('FBQV22', PP 19,758)—Dominant central leader, branches at 45 to 60° angle to main trunk, turning upward to form a pyramidal habit, becoming broad-pyramidal with age; 12-year-old parent tree was 25' by 21' with a 12" caliper; leaves are long, narrow, lustrous dark green and persistent through winter; excellent for streets and parking islands because of upswept branches; introduced by Fish Branch Tree Farm, Zolfo Springs, FL.

'Cannon-Sharp' (PP 19,608)—Rapid growth, upright, uniform, dense growth habit, dominant central leader, lateral branches borne at 60° angle to vertical; attractive, glossy dark green leaves; discovered as a chance seedling, introduced by Adam Cannon, Brooksville, FL.

Cathedral® ('SDLN', PP 12,015)—Central leader with wide-angle branches, dense, full growth habit, dark green leaves; introduced by Shadowlawn Nursery, Penny Farms, FL (see www.shadowlawnnursery.com).

'Grandview Gold'—Gold-colored foliage; found by Earl Vallot, Grandview Nursery and offered by Louisiana Nursery.

Highrise® ('QVTIA', PP 11,219)—Upright pyramidal-columnar form that will revolutionize planting in narrow spaces, probably 2 1/2 to 3 times as high as wide at maturity; introduced by Tree Introductions, Inc., Athens, GA.

'K-1' (PP 17,249)—Dense, upright columnar habit, secondary branches borne at 45° angle and arch upward to produce a compact, dense canopy; selection from 10,000 seedlings in 1998, introduced by John Kelz, St. Augustine, FL.

Millennium® ('CLTF2', PP 11,097)—Rapid growth, central leader, strong secondary branching, thicker stem caliper; large dark green leaves; 13-year-old tree was 29' by 29' with 13" caliper measured 12" above the soil line; introduced by Cherry Lake Tree Farms, Inc. Groveland, FL.

'Orange Island'—Superior foliage; habit, more evergreen; grows faster; produced from seeds; Live Oak Gardens, New Iberia, CA.

Park Side® ('FBQV1', PP 19,759)—Branch angles at 75° to main trunk, many smaller branches develop off the secondary branches forming a full canopy at an early age; habit is broad-pyramidal, becoming more ovate-rounded with age; emerging leaves light green, mature dark green; the parent tree, 13-years old, was 25' by 18' with 11" caliper; introduced by Fish Branch Tree Farm, Zolfo Springs, FL.

Southern Shade®—A seed-produced cultivar derived from a selected seed source; tree described as classic "medium-sized" tree with short, broad trunk buttressed at the base, horizontal long branches, and broad-spreading, dense crown; from Cherry Lake Tree Farms, Inc. Groveland, FL.

PROPAGATION: Seeds are the preferred method although Texas A&M has experimented with cutting propagation; see *HortScience* 24:1043 (1989) for cutting information; see *HortScience* 23:777 (1988) for seed work; Morgan used 10,000 ppm KIBA with great success on younger trees; see Dirr and Heuser, 2006 for details.

ADDITIONAL NOTES: State tree of Georgia. May live 200 to 300 years. Considered a climax species in coastal Louisiana and along the east coast and outer banks of North Carolina. Tolerant of saline conditions. The wood is exceedingly strong and one of the heaviest of native woods; was used for ribs and other hull parts of wooden ships. The acorns are eaten by many songbirds as well as quail, turkey, squirrel and deer. Several geographical varieties have been noted. *Quercus fusiformis* Small (var. *fusiformis* (Small) Sarg.) is a small shrubby tree that occupies sandstone ridges in central Texas and Oklahoma. National champion is 48' by 80' in Graham, TX. Variety *maritima* (Michx.) Sarg. integrates with the species and tends to be coastal from Virginia to Louisiana and Florida. Like many varieties, hairs are often being split in attempts to quantitatively separate them.

NATIVE HABITAT: Virginia to Florida, west to Oklahoma and Texas into Mexico. Introduced 1739.

Quercus virginiana
var. *maritima*

RELATED SPECIES: Two smaller, often shrubby, versions of *Q. virginiana* are *Quercus geminata* Small, Sand Live Oak, and *Quercus myrtifolia* Willd., Myrtle Oak. The former grows 20 to 30' high (national champion 64' by 103' in Alachua County, FL), is similar to *Q. virginiana* in growth form and acorns but flowers 2 to 3 weeks later, occurs on coastal dunes and inland sands from southern North Carolina to Mississippi, drought tolerant, Zone 7 to 9. The latter, *Q. myrtifolia*, grows 10 to 20' high (co-national champions 35' by 30' in Baldwin, AL and 37' by 16' in Camden, GA), with 3/4 to 2" (3") long, obovate, dark green leaves. The acorns are sessile or stalked (1/5" long), the caps covering 1/4 to 1/3 of the nut and mature the second season, rarely the first. Occurs in sandy pine or oak-pine scrub. Requires good drainage under cultivation. South Carolina to Mississippi. Zone 8 to 10.

Also in this complex of evergreen (tardily deciduous) species resides *Quercus chapmanii* Sarg., Chapman Oak, with oblong to elliptic leaves unlobed or irregularly wavy margined to shallowly lobed toward apex. First year stems finely grayish hairy. Acorns 3/4 to 1" long, cap covering 1/3 to 1/2. Grows to 30'. National champion 45' by 41' in Marion County, FL. Sandy barrens and scrub, dunes, ridges. South Carolina to Alabama. Zone 8 to 9.

A nifty hybrid, *Quercus xcomptoniae* Sarg., embodies *Q. virginiana* and *Q. lyrata*. Habit is pyramidal, fast growing, tardily deciduous leaves, a young tree on campus has produced heavy acorn crops, about 1" long, ellipsoidal, dark brown-black, covered about 1/2 by cap, will grow to 60'. Selection work is underway with this species. I believe there are great possibilities for superior introductions. Introduced 1920. Listed as Zone 5 but best in (6)7 to 9.

Quercus myrtifolia

Rhamnus cathartica L. — Common or European Buckthorn

(ram'nus ka-thar'ti-ka)

FAMILY: Rhamnaceae

LEAVES: Subopposite, simple, elliptic or ovate, 1 1/2 to 3" long, half as wide, sometimes almost equal in width, acute or obtusish, rounded or subcordate at base, sometimes broad-cuneate, crenate-serrulate, dark glossy green above, light green and usually glabrous beneath, with 3 to 5 pairs of veins; petiole—1/4 to 1" long.

BUDS: Imbricate, appressed, elongated, brownish black, glabrous, 1/4" long.

STEM: Slender, somewhat grayish, gray-green or brown, glabrous, terminal bud a modified spine usually as long as or longer than the buds.

SIZE: 18 to 25' in height with a comparable spread; national champion is 27' by 41' in Halifax, NC.

HARDINESS: Zone 3 to 7.

HABIT: Large shrub or low-branched tree with a rounded, bushy crown of crooked, stoutish stems; may sucker from base to produce a thicket.

RATE: Medium to fast.

TEXTURE: Medium in leaf, coarse in winter.

LEAF COLOR: Dark glossy green in summer, very clean foliage throughout the growing season, excellent if foliage is the only ornamental asset desired; fall color is a disappointing green to yellowish green, leaves hold quite late.

FLOWERS: Usually dioecious, small, yellowish green, 4-petaled, May, borne in 2- to 5-flowered umbels and form a dense cluster at the base of the young shoot.

FRUIT: Berry-like drupe, 1/4" diameter, glossy, black, not particularly effective, birds like them; ripen summer into fall.

CULTURE: Easily transplanted, adapted to difficult conditions, withstands urban environments; pH adaptable, at home on limestone, high pH soils; sun to moderate shade; a very tough, durable tree for areas where few other trees will survive; the fruits are eaten by the birds and the seeds deposited in hedgerows, shrub borders and other out-of-the-way places; is actually a noxious weed.

DISEASES AND INSECTS: Leaf spots, rust, powdery mildew, aphids, scales; none are serious except the rust (*Puccinia coronata*) which can cause considerable damage to oats; eradication of buckthorn is the recommended control measure.

LANDSCAPE VALUE: Possibly as a background, screen or hedge under difficult growing conditions; has become a terrible weed in Midwest and East and I remember the infestations at the Morton Arboretum; be careful because one plant yields many, especially with the birds as planters.

PROPAGATION: Seed, 60 to 90 days in moist medium at 41°F; cuttings are apparently somewhat difficult although 1,000 ppm IBA or higher may suffice.

NATIVE HABITAT: Europe and western and northern Asia, naturalized in eastern and midwestern United States.

RELATED SPECIES:

Rhamnus davurica Pall., (ram'nus da-vur'i-ka), Dahurian Buckthorn, is a 25 to 30' high (usually smaller under cultivation), spreading shrub or small tree with stout, often spinescent, stems. Foliage is lustrous dark green; differs only in longer and uniformly wedge-shaped leaves. Fruit is black with 2 large seeds much like *R. cathartica*. Extremely hardy and durable, well-adapted to difficult situations. Limitedly available in commerce. Have seen the plant literally consume waste areas; is a weed unless checked. Northern China, Manchuria, Korea, Japan. Introduced 1817. Zone 3 to 6(7).

Rhamnus frangula L. (*Frangula alnus* Mill. is new name according to GRIN) — Glossy Buckthorn, also called Alder Buckthorn

(ram'nus frang'ū-la)

LEAVES: Alternate, simple, oval or obovate to obovate-oblong, 1 to 3"(4") long, about half as wide, acute, rounded or broad-cuneate at base, entire, lustrous dark green above, lighter green and often slightly pubescent beneath, with 8 or 9 pairs of prominent, impressed veins; petiole—1/4 to 1/2" long.

BUDS: Terminal-naked, pubescent, brownish, foliose, much larger than laterals; laterals-brownish, small.

STEM: Slender, pubescent on young stems, eventually becoming glabrous; prominently marked on young and old stems with gray, rectangular, vertical lenticels.

SIZE: 10 to 12' possibly to 18' in height and probably 8 to 12' or greater in spread.

HARDINESS: Zone 3 to 7.

HABIT: Upright, spreading, large shrub or small, low-branched tree with long arching branches yielding an upright-oval outline; quite gangly and open.

RATE: Medium to fast.

TEXTURE: Medium in leaf, medium-coarse in winter.

LEAF COLOR: Dark glossy green in summer changing to greenish yellow or yellow in fall; the fall color is usually a poor greenish yellow.

FLOWERS: Perfect, creamy-green, parts in fives, 2 to 10(10 to 20) together in leaf axils of new growth, not showy, bees love them, May.

FRUIT: Berry-like drupe, 1/4 to 1/3" across, in maturation passes from red to purple-black, effective from July through September, 2 seeds.

CULTURE: Transplants well, adaptable, sun or partial shade, prefers well-drained soil; I noticed where Illinois students made paths through the hedges (*Rhamnus frangula* 'Columnaris'), a significant decrease in height was evident on either side of the path compared to non-trafficked areas.

DISEASES AND INSECTS: Until 1975 no serious problems had been reported. However, many of the hedge plants on the University of Illinois campus exhibited a dieback disorder typical of canker or wilt infestation. Don Schoeneweiss reported in the *Plant Disease Reporter* 58:937 that low temperature stresses predisposed Tallhedge to the fungus *Tubercularia ulmea*. He was consistently able to isolate the fungus from stem cankers that were girdling the shoots.

LANDSCAPE VALUE: Species is basically worthless for landscape considerations; falls into the weed category for the birds deposit the seeds everywhere and plants are found in unexpected places; cultivars offer some hope.

CULTIVARS:

'Aspleniifolia'—Very fine texture, slow growing, but interesting, not common, will grow 10 to 12' high and 6 to 10' wide; leaves not cut but narrowed and with an irregular margin; offers an almost ferny texture to the landscape.

'Aspleniifolia'

'Columnaris'—Narrow, upright deciduous shrub prized for hedges, has been overused in the Midwest; referred to as Tallhedge Glossy Buckthorn, will come partially true-to-type from seed; is usually produced from cuttings.

Fine Line® ('Ron Williams', PP 14,791)—Actually appears to be a hybrid of 'Aspleniifolia' and 'Columnaris'; habit distinctly upright with the graceful, narrow, arching, lustrous dark green leaves of 'Aspleniifolia'; will flower and fruit; listed as growing 5 to 8' high; Zone 5; if it does not get ticketed by the Invasive Police, a handsome addition to our gardens; Proven Winners®; seed viability is low, only 3% compared to 98% for the species.

'Minaret'—Listed in RHS Plant Finder 2008–2009.

PROPAGATION: Seed, 60 days in moist peat at 41°F; softwood cuttings collected in June or July will root well when treated with 8,000 ppm IBA.

ADDITIONAL NOTES: From a landscape viewpoint, difficult to become overly excited. Largely weedy, highly invasive plants. Need to keep use to a minimum. The genus contains about 150 species with only a few of garden interest. Had the opportunity to catch up with *R. purshiana* DC. (now *Frangula purshiana* (DC.) J.G. Cooper), Cascara, in Oregon; amazing similarity in leaves with *R. frangula* (*Frangula alnus*) and the others mentioned herein. Leaves turn rich yellow in autumn with red, maturing to black, fruits.

NATIVE HABITAT: Europe, western Asia, north Africa; naturalized in eastern and midwestern United States. Long cultivated.

RELATED SPECIES:

Rhamnus alaternus L., (ram'nus a-lā-ter'nus), Italian Buckthorn, is a medium-sized, evergreen shrub growing 10 to 12' high. The oval to obovate, dark glossy green leaves average 3/4 to 2" long and 1/2 to 1" wide. Yellow-green, 5-merous, small flowers in a compact panicle; obovoid, red to black, 1/4" diameter drupe with 3 seeds. The species is seldom seen in U.S. cultivation but 'Argenteovariegata' is a pretty creamy white-margined form that grows 6 to 8'(10') high. I have seen it many times in Europe; first time in the U.S. at Hawksridge Nursery in a polyhouse. Certainly would prove commercial if adaptable. Considered less cold hardy than the species. The species is well adapted to urban and maritime conditions. Considered invasive and considerable literature is available on the species. Mediterranean region. Introduced about 1700. Zone 8 to 9?

Rhamnus caroliniana Walter (now *Frangula caroliniana* (Walter) A. Gray according to GRIN) — Carolina Buckthorn, Indian Cherry
(ram'nus ka-rō-lin-i-ā'na)

LEAVES: Alternate, simple, elliptic-oblong or lance-oblong, 2 to 6" long, acute or acuminate, rounded, serrulate or entire, lustrous dark green above, essentially glabrous, 8 to 10 impressed vein pairs; petiole—1/2" long, pubescent.

Rhamnus caroliniana, Carolina Buckthorn or Indian

Cherry, is a handsome shrub or small tree with dark green, 8 to 10 vein-paired leaves. The real beauty resides in the 1/3" diameter, globose, sweetish fruits (3 seeds) that change from red to black as they mature. I have grown the plant for several years and am most impressed with the handsome foliage and interesting fruits. Fruits ripen in August (red) and remain on the plant until October or later by which time they have turned black. It is quite attractive in fruit and is often brought in for positive identification. It can supposedly grow 30 to 40' high but in the Piedmont of Georgia I have seen plants in the 10 to 15' range. National champion is 25' by 24' in Clarksville, TN. New York to Florida, west to Nebraska and Texas. Introduced 1727. Zone 5 to 9.

Rhamnella franguloides (Maxim.) Weberb., (ram-nel'a fran'gū-loi-dēz), is closely related to *Rhamnus*, the leaf shape and veinal pattern similar to *R. caroliniana*. Dark green leaves turn birch-yellow in early to mid-November, Zone 7. Bears orange-colored, rounded, 1/4" fruits. Large, straggly shrub or small tree; largest I observed was 20' high. A novelty plant that may have invasive potential. Sun and shade adaptable. China.

Raphiolepis umbellata (Thunb.) Mak. — Yeddo (Yedda) Raphiolepis, Indian Hawthorn
(raf-i-ō-le'pis um-bel-lā'ta)

FAMILY: Rosaceae

LEAVES: Alternate, simple, evergreen, ovate to broad-ovate, 1 to 1 1/2"(3") long, 3/4 to 1 1/4"(2") wide, apex ranges from slightly acute to obtuse to emarginate, base rounded, leaves near end of stem entire, those lower on stem serrated to varying degrees, young leaves gray floccose above and below when emerging, finally extremely leathery, glabrous, lustrous dark green above, dull beneath, in winter assuming a slight purplish tinge especially on margin; petiole—1/4 to 1/2" long, stout, with small blackish stipules.

BUDS: Flower—terminal, imbricate, scales loose at tips, 1/4" high, reddish purple, pubescent; laterals—small, almost imbedded in bark.

STEM: Stout, pubescent at tip, finally glabrous, brown, streaked vertically with gray epidermal layer; pith—solid, green.

SIZE: 4 to 6' by 4 to 6', some forms growing 10 to 15' high; cultivars usually smaller.

HARDINESS: Zone 7 to 10, actually shaky in Zone 7; Mr. Will Corley, Georgia Experiment Station, evaluated 20 species and cultivars of *Raphiolepis* for hardiness and leaf spot resistance. In 1985, after

–8°F, all were killed to the ground. At –3°F in 1983, the hardiest form was an unnamed, Plant Introduction (PI) accession from Japan. Interestingly, the PI showed near immunity to leaf spot while ‘Majestic Beauty’, ‘Snow White’, and ‘Ovata’ (var. *ovata*) showed good resistance; ‘Enchantress’, ‘Fascination’, and ‘Pink Lady’ the greatest susceptibility. Study in *J. Environ. Hort.* 10(1):1–3 (1992) showed that four new introductions were as cold hardy as the parent but maximum hardiness was still only 5 to 0°F. In April, 2007, Easter weekend, the Southeast was clobbered with a late freeze, 24 to 26°F, and new growth was killed. This was repeated on the new growth of numerous plants. Previous year’s leaves were not injured.

HABIT: Dense, mounded-rounded evergreen shrub; leaves clustered at ends of branches like *Pittosporum*; some forms loose, open, making small trees if trained.

TEXTURE: Medium, rather stiff in appearance.

LEAF COLOR: New leaves almost gray-green, emerging in March (Athens), finally glossy dark green to blue-green in summer often assuming an off color during winter, somewhat of a subdued purple-green.

FLOWERS: Perfect, white, 5 petals, 5 sepals, 15 to 20 stamens, 2 to 3 styles, 3/4” diameter, slightly fragrant, borne in dense, upright, tomentose, 2 to 3” high and wide panicles or racemes; mid to late April into early May (Athens), mid April, Sarah P. Duke Gardens, Durham, NC, full flower mid March, Leu Gardens, Orlando, FL; makes a respectable show.

FRUIT: Subglobose, 3/8 to 1/2” diameter, purple-black to bluish black, 1- to 2-seeded berry (possibly pome); ripen in early fall and persist attractively through winter; at times so abundant as to resemble a blueberry bush.

CULTURE: Transplants readily from containers; prefers moist, well-drained soils, pH 6 to 7; will tolerate drought; adaptable to containers and above ground planters; tolerates restricted root space; good plant for coastal areas because of salt tolerance, injured at 0°F for many leaves were browned, probably best in Zone 8 although abundant in Zone 7, do not prune in late summer for the new shoots that may develop are extremely frost sensitive; sun and shade tolerant, in the latter moisture is retained longer on the leaves leading to increased leaf spot.

DISEASES AND INSECTS: Leaf spot in moist shady locations (also in sun), have seen plants virtually defoliated, disease caused by *Entomosporium* species, symptoms are similar to those on *Photinia xfraseri*, red lesions develop on the leaf surface, may coalesce and kill entire leaf, disease more severe where moisture persists on leaves such as in semi-shaded locations.

LANDSCAPE VALUE: Have observed it in many landscape situations in the South; mass, unpruned hedge, containers, nice for textural effect; flowers and fruits are attractive; fruits tend to be lost in the dark green foliage especially when viewed at long distance; largely abandoned in late 1980’s due to cold sensitivity and disease, memories are short and new cultivars have appeared with greater cold hardiness and disease resistance, am “seeing” the plant by the millions return to Zone 7, Atlanta–Athens, widely used in large-scale masses; highly susceptible to deer browsing.

CULTIVARS: Could be cultivars of *R. indica* or *R. umbellata*. Have included all herein for ease of comparison. Corley’s data on cold hardiness and disease resistance are worth monitoring.

‘Ballerina’—Vibrant rosy pink flowers with intermittent flowers in summer, foliage turns reddish color in winter; rounded habit 3 to 4’; *R. indica* form, killed at –3°F.

‘Bay Breeze’—Broad-mounded form, 2 1/2’ by 6’; new leaves bronze, finally lustrous dark black-green, leaves slightly twisted-undulating; rich deep pink flowers; in our trials more heavily browsed by deer, minimal leaf spot; Hines introduction; when first observed I rated this the best in terms of foliage and flowers; unfortunately, leaf spot susceptibility is worse than previously noted; probably best in drier areas of its adaptability.

‘Becky Lynn’—Compact-mounding habit, 2’ by 4’; petite dark green leaves; dark pink flowers.

‘Betsy’—Selected for leaf spot resistance, introduced by Tom Dodd, Jr. and named for his daughter.

‘Blueberry Muffin’—A dense rounded habit as I witnessed the plant in 1994, however, I believe the number of cuttings removed kept it compact; white flowers, blue-black fruit, leaves turn purple in winter; was free of leaf spot when viewed by the author; JC Raulston Arboretum introduction; J.C. gave me fruits that were cleaned, sown and produced many vigorous wild seedlings, none of which were small, seedlings are susceptible to leaf spot.

‘Bonfire’—Pretty selection by Rick Crowder with red to red-purple new growth, the color holding but eventually turning green, each new-growth flush is reddish; foliage has been clean; vigorous grower, expect 3 to 5’ high and wide; worthy addition to the *Raphiolepis* family, probably *R. indica*, introduced from Japan, named by Bonnie Dirr.

Calisto® (PPAF)—Dark green, shiny leaves with a twist (spiral) to long axis, burgundy winter foliage; beautiful, vibrant dark pink flowers; flowers fully open mid April, Dearing, GA; dense, compact habit, 2 1/2 to 3’ by 4’; foliage is reminiscent of ‘Bay Breeze’; if leaf spot resistant, it will become the classic pink by which all others are judged; PDSI/Flowerwood introduction.

Cameo™ (‘Ponto’s Pink Clara’, PP 7,403)—Dense mounding shrub, 4’ by 4’, new foliage reddish colored, matures to rich dark green; bright pink single flowers in March–April, sporadic flowers in fall; bred at Ponto Nursery, Vista, CA, introduced by Hines Nurseries, Inc., Houston, TX.

‘Charisma’—Double, soft pink flowers, rich green foliage, tight mounded growth habit; a Monrovia introduction; killed at –3°F.

- 'Clara'—White flowers cover plant in spring; red new growth maturing to dark green; low evergreen shrub, 4' high and 4' wide; killed at -3°F ; same as 'Snow White'?
- 'Coates Crimson'—Crimson-pink flowers; compact spreading, slow-growing, 2 to 4' high and wide; killed at -3°F ; *R. xdelacourii* selection.
- 'Dwarf Pink'—Rose-pink flowers on a 4' high plant; bronze-red winter foliage.
- Eleanor Taber™ ('Conor', PP 9,398)—Vigorous mounded form, 3' by 4'; large dark green leaves; pinkish flowers; good leaf spot resistance; performed well in Georgia tests, more fireblight resistant than Olivia™; Flowerwood Nursery introduction.
- Enchantress® ('Pinkie', 'Moness')—More compact than the species; rose-pink flowers in large panicles from late winter through early summer depending on geographic location; lustrous dark green leaves; moderate to severe injury at -3°F ; 3' by 5'.
- 'Eskimo'—A plant introduction accession from the U.S. National Arboretum that Will Corley evaluated at the Griffin Experiment Station, was the hardiest and most leaf spot resistant in Will's trials; the progenitor parent for 'Georgia Charm' and 'Georgia Petite'; parent plant 6' by 8', dark green leaves, white flowers; named 'Eskimo' and grown by Wight Nurseries, Cairo, GA.
- 'Fascination' (PP 2,644)—Compact, rounded form with large leaves and flowers; petals pink toward the edges, white in the center creating a star-like effect, moderate to severe injury at -3°F ; *R. xdelacourii* selection.
- 'Georgia Charm' (PP 9,982)—Compact, 4' by 3', dark green leaves, white flowers; more cold hardy to 5°F and leaf spot resistant; parentage supposedly 'Eskimo' $\times$ 'Ovata'; introduced by University of Georgia.
- 'Georgia Petite' (PP 9,983)—Compact mound, 2 1/2' by 3'; white flowers, mid to late March in Dearing, GA; selected for cold and leaf spot tolerance; parentage as above; both contract leaf spot but are more resistant than average; at Monrovia Growers, Cairo, GA, 'Georgia Petite' was more upright in habit than 'Georgia Charm'.
- 'Harbinger of Spring'—Deep pink flowers in loose panicles; 3" long thick glossy green leaves; rounded habit, 5' by 5'; moderate injury at -3°F .
- 'Hines Darkleaf' (PP 8,635)—Low-growing form, 2 to 2 1/2' high, 6' or greater in width; bronzy maroon to green new growth matures to glossy rich green, with foliage becoming dark purple in fall, leaves are somewhat recurved; flowers are single, bright pink with white center, sporadic flowers in fall; thought this may be same as 'Bay Breeze'; released by Hines Nurseries, Santa Ana, CA.
- 'Improved White'—Thick, curly, leathery leaves; white flowers; Live Oak Gardens introduction.
- Indian Princess® ('Monto', PP 5,862)—Broad bright pink flowers, fade to white; heavily tomentose new leaves become glabrous and bright green; compact broad mounded form, 3' by 5'; a Monrovia introduction.
- 'Jack Evans'—Vivid pink flowers in large panicles; strong upright habit, 4 to 5' by 4'; killed at -3°F .
- Majestic Beauty™ ('Montic', PP 3,349)—Large form probably growing 8 to 10' and larger, often trained into a small tree; leaves up to 4" long, bronze turning deep green; flowers are pinkish and fragrant, has shown good resistance to leaf spot; killed at -3°F ; have observed in numerous plantings on Jekyll and St. Simons Islands, GA; this is the most robust growing of the common cultivars, have seen it listed as a *R. xdelacourii* selection.
- 'Minor' (Gulf Green™)—Smaller dark green leaves, white flowers, upright 3 to 4' high; definitely not minor except for the leaves; purple-black fruit, marketed as Gulf Green™ by Hines.
- Olivia™ ('Conia', PP 9,399)—Excellent large dark green leaves; white flowers; dense mounded habit, 4' by 4 to 5', also listed as 2' by 4', I estimate between the two listed sizes based on older plants at the Raulston Arboretum; high leaf spot resistance; has outgrown and outperformed 'Eleanor Taber', 'Bay Breeze', 'Georgia Charm', and 'Georgia Petite' in Georgia trials; every visitor who knows anything about *Rhaphiolepis* asked the identity of Olivia™; continued evaluations throughout the Southeast showed Olivia™ was more fireblight susceptible than Eleanor Taber™.
- 'Pink Cloud'—Pink flowers and compact growth habit, 3' by 3 to 4'; may be the same as 'Springtime'?
- 'Pink Dancer'—Compact, mounding habit, 16" by 36"; lustrous leaves with undulating margins, become bronze or maroon in cold weather; deep pink flowers.
- 'Pink Flush'—Pink flowers in spring, intermittent flowering in summer; reddish foliage color in winter; rounded outline, 3 to 4' high; I believe this is the same as 'Ballerina'.
- 'Pink Lady'—Deep pink flowers; vigorous form, 4 to 5' by 4 to 6'; resistant to leaf spot; the same as 'Enchantress'?; slight to moderate injury at -3°F .
- 'Pink Mound'—Dense, semi-dwarf habit; leathery dark green leaves; rich pink flowers; seedling of 'Snow White'; Live Oak Gardens introduction.
- 'Pinkie'—Pink flowers on a 3' high, compact shrub.
- Rosalinda® ('Conda', PP 9,056)—Large-growing form; bronzy red new foliage, changing to dark green; dark pink, fragrant flowers; Flowerwood introduction.
- 'Rosea'—Light pink flowers; loose, more graceful habit, 3 to 5' high and 5 to 6' wide; new growth bronze; also a compact form with similar attributes ('Rosea Dwarf'); 'Rosea Dwarf' was killed at -3°F .

Snowcap® ('Corleyscourii', PP 15,544)—Excellent rounded-mounded almost dome-shaped habit; extremely dense foliage, dark green with slight luster, turning burgundy-merlot in cold weather; extremely resistant to *Entomosporium*; white flowers in abundance; blue-black fruits; derived from Will Corley's cold-hardy material and appears more cold resistant than most; listed as a *R. xdelacourii* selection; introduced by John Barbour, Bold Spring Nursery.

Snow Pink™ ('Sopink', PP 14,388)—Characteristics comparable to 'Snow White' such as disease resistance, compact habit, red foliage and brilliant pink flowers over a long period; PDSI/Flowerwood introduction.

'Snow White'—Dwarf form with a spreading habit; pure white flowers from early spring into early summer; foliage lighter green than other cultivars, good resistance to leaf spot; moderate to severe injury at -3°F.

Spring Rapture® ('Monrey', PP 5,215)—Rose-red flowers cover a compact, mounding shrub, 3 to 4' high and wide; a Monrovia introduction; slight to moderate injury at -3°F.

Spring Sonata™—Rounded-mounded, 4' by 5'; dark green leaves; flowers later; disease resistant; PDSI/Flowerwood introduction.

'Spring Song'—Flowers apple-blossom pink and borne over a long period; *R. xdelacourii* selection.

Springtime® ('Monme')—More vigorous grower; flowers pink, late winter to early spring; foliage bronzy green, thick and leathery; moderate to severe injury at -3°F; 4 to 6' high; same as 'Pink Lady'?; Monrovia introduction.

White Enchantress® ('Monant')—Low-growing form with single white flowers, 3' by 5'; hardy to 0°F, moderate to severe injury at -3°F; Monrovia introduction.

PROPAGATION: Seed collected in mid-February, pulp removed, direct down, germinated in high percentages. Seed have no dormancy and will germinate in high percentages. Cuttings: semi-hardwood to hardwood can be rooted, 2,500 ppm IBA + 2,500 ppm NAA, wound, is an effective treatment. I have had miserable success rooting this genus and cuttings have been taken in fall and winter. An interesting Florida study mentioned that best rooting occurred from June to August with 10,000 to 20,000 ppm IBA quick dip, wound, perlite:vermiculite medium, 47% shade and mist. Rooting ranged from 90 to 100%.

NATIVE HABITAT: Japan, Korea. Introduced before 1864.

RELATED SPECIES: Based on my explorations around the South the *Raphiolepis* species are somewhat confused. Although *R. indica* is listed as the plant most in cultivation the technical description favors either the above or a hybrid *R. xdelacourii* André, (*R. umbellata* × *R. indica*). It showed slight to moderate injury at -3°F. The hybrid was raised by Delacour, gardener at the Villa Allerton, Cannes, France. Numerous forms varying in leaf and flower color were raised. It displays moderate to good resistance to leaf spot. I surmise some of the hybrids may have been named, renamed, and represent a few of the cultivars listed under *R. umbellata*. Louisiana Nurseries lists 'Belle' with deep pink flowers and tall growing; 'Elizabeth' with pink flowers over an extended season on a 4' by 5' shrub; 'Janice' with bright pink flowers and dwarf compact habit; 'Peggy' with white flowers, dark green foliage and compact habit; and 'Pink Charm' with deep rose-pink flowers on a low-growing framework.

***Raphiolepis indica* (L.) Lindl. ex Ker-Gawl., (raf-i-ō-le'pis in'di-ka), Indian Hawthorn,** is less hardy than *R. umbellata* and *R. xdelacourii*. The 2 to 3" long leaves are thinner and narrower, lanceolate, acute or acuminate, more sharply serrate and the flowers either white or pinkish. From a landscape standpoint this species is probably similar. I have not observed a single plant of the species on the Georgia campus. Southern China. Introduced 1806. Zone 8 to 9(10).

Rhododendron L. — Rhododendrons and Azaleas

FAMILY: Ericaceae

The genus *Rhododendron* comprises 800 to 900 species and infinite numbers of cultivars due to the ability of the species to freely hybridize. The continuing avalanche of cultivars has buried this author with considerable self-doubt relative to developing an effective presentation. My conclusion: no effective way exists. Individuals smarter and broader-versed have written monographs on the genus. I have checked and cross-checked articles, catalogs, books, living collections, and at best assembled a framework of descriptions that might assist the reader. Rest assured that even the experts do not know the rhododendron genus in its broadest sense.

The improvements in rhododendrons (foliage, flower color and quality, hardiness and growth habit) have come about through hybridization. There is a need for cold hardy forms with good flower color. Many of the hardy types available are endowed with the lavender-purple-magenta colors offensive to many people. Rhododendrons are indigenous to many parts of the world but the strongest concentrations of hardy, colorful,

useful types exist in China, Japan, and the eastern United States. Greatest cultural success in the States is achieved in the Pacific Northwest and the eastern United States where soils and atmospheric conditions are close to optimum. The following list is not complete and was not intended to be. The types listed represent some of the hardier and more common forms. A good rhododendron display is without equal and a poll of gardeners (asking them their favorite shrub) indicated rhododendrons were *numero uno*. For additional information see Cox, Davidian, Greer, Bowers, Leach, Bean, Galle, Reilley, Towe, Bryant, Cullen, Salley, Dunmire, Leslie, *The New RHS Dictionary of Gardening*, Hillier 2002, and join the American Rhododendron Society, www.rhododendron.org.

I recommend that readers who deserve deeper knowledge of the origin and breadth of the various cultivar groups check the internet. The Robin Hill azaleas provide a great starting point for there are pages of history charting their development by Robert Gartrell, an amateur breeder. A list of 69 introductions is presented along with photos and descriptions of each cultivar. Likewise for Encore®, Girard, Northern Lights azaleas, *ad infinitum*. Carlson's Gardens, www.carlsonsgardens.com, one of the best purveyors of cold hardy azaleas (50 miles north of New York City), presents its offerings only through an on-line catalog with great photos and text. The great Weston Nursery, Hopkinton, MA, has contributed many superb, cold-hardy rhododendrons and azaleas (see www.westonnurseries.com). I tried to update their rhododendron offerings in this edition with about 29 additions. Briggs Nursery, Elma, WA, (www.briggsnursery.com), is a leader in tissue culture production of rhododendrons and azaleas. For a peek at what's new and about to hit the market, peruse their catalog or website. For example, the 2008-2009 catalog lists 41 new (to their production) *Rhododendron* taxa. Same catalog describes and illustrates 71 azalea and an astronomical 180 rhododendron taxa. Another source of tissue culture *Rhododendron* taxa is Mountain Shadow Nursery (www.mtshadow.com) owned by Steve McCulloch. The message herein, if more information is desired, then GOOGLE.

The truism is genuine that nurseries B to Z will often grow the plants that nursery A offers. The large wholesale nurseries produce many of the standards like 'Nova Zembla', 'P.J.M.', 'Delaware Valley White', 'George Taber', 'Gibraltar', etc., because of ironclad performance and reasonable name recognition. The new hybrids and cultivars have a difficult time breaking the stranglehold of the few. I am not sure this will ever change. Small specialty nurseries offer the newer, perhaps better, azaleas and rhododendrons, and should be supported. I have observed our Georgia industry integrating the newer and better Girard, Robin Hill, and North Tisbury azaleas into production. Older varieties must be removed from production to make room for the new. At any time in the production cycle of the large nurseries a finite number of rhododendron members can be grown. With this stated, it is a sad commentary on the beautiful evergreen and deciduous azaleas that they are at the bottom of the economic container nursery food chain. Yes, azaleas, particularly the evergreen types, sell for less than almost all other container-produced plants of similar size.

Bonnie and I have "given up" on the large-leaf evergreen rhododendrons in our Georgia garden and grow only the deciduous native azaleas and a few small evergreen azaleas. See my comment about *R. hyperythrum*. The April-May flowering natives are exquisite with riotous colors of white, pink, rose, yellow, orange, and red and are often quite fragrant. We have tested the early Encore® azaleas from Flowerwood Nursery and appreciate their August through November flowers. Bonnie and I spent several afternoons evaluating Encore® performance. Unfortunately, they do not appear to be particularly cold hardy and cultivar-by-cultivar evaluation will be necessary. See this section and discussion of the now 23 cultivars. On September 19, 2008, I witnessed a mass planting of one of the double rose-red Encore® on the University of North Carolina campus. Loaded with flowers, not simply spitting same, and so out of season as to prove spectacular.

Travels have taken me to the Highlands of Scotland, particularly Inverewe, Arduaine, and Crarae Gardens where I raised my eyes skyward to frame the large Himalayan rhododendrons. Magnificent leaves, *R. sinogrande* Balf. f. & W.W. Sm.; rich red-brown exfoliating bark, *R. barbatum* Wall. ex G. Don.; and yellow flowers so rich, *R. macabeaenum* G. Watt ex Balf. f.; were in full plumage. Realistically, only memories were carried home. However, with the great English plantsman, Roy Lancaster, I trekked Rabun Bald, second highest mountain in Georgia at 4,696, in late June 1997. We experienced *R. arborescens*, *R. calendulaceum*, and *R. catawbiense* in flower. The thrill was not too different for Roy from his adventures in China and the Himalayas. After all, rhododendrons and azaleas in the wild in any part of the world are magnificent experiences.

DIFFERENCES IN RHODODENDRONS AND AZALEAS

Actually, all azaleas are included in the genus *Rhododendron*. There are no clear cut lines for distinguishing all azaleas from all rhododendrons but:

1. True rhododendrons are usually evergreen but there are exceptions such as *R. mucronulatum* and *R. dauricum*.
2. True rhododendrons have 10 or more stamens and leaves are often scaly or with small dots on their undersurface.
3. Azalea flowers have mostly 5 stamens, leaves are never dotted with scales and are frequently pubescent.
4. Recent hybrids between true rhododendron and true azaleas have intermediate stamen numbers, Encore® azaleas are an example.

Rhododendron catawbiense Michx. — Catawba Rhododendron

(rō-dō-den'dron ka-taw-bi-en'sē)

LEAVES: Alternate, simple, evergreen, elliptic to oblong, 3 to 6" long, 1 to 2" wide, obtuse and mucronulate, rounded at base, entire, dark green above, light green below, glabrous, leathery texture; petiole—1/2 to 1 1/4" long.

FLOWER BUDS: Large-1/2" long, scaly, pointed, yellowish green.

STEM: On new growth yellowish green changing to brown with age, glabrous.

SIZE: 6 to 10' in height, rarely 15 to 20', spread 5 to 8' or more; national champion 25' by 15' in Great Smoky Mountains National Park, NC.

HARDINESS: Zone 4 to 8.

HABIT: Heavy evergreen shrub with large, dense foliage to the ground; often leggy in unfavorable locations; usually taller than wide although does assume a rounded outline.

RATE: Slow.

TEXTURE: Medium-coarse in all seasons.

LEAF COLOR: Dark green, very handsome; often in winter under exposed conditions will develop a yellow-green color.

FLOWERS: Lilac-purple, sometimes purplish rose, with green or yellow-brown markings on the inside of the corolla, 1 1/2" long, 2 1/2" broad; mid to late May in Urbana, IL, early June, Boston, (late April to late May in Athens, GA) depending on the cultivar; flowers borne in 5 to 6" diameter umbel-like racemes (trusses), species as observed on Rabun Bald at ~4,000' in full flower late June.

FRUIT: Capsule, dehiscent, 5-valved.

CULTURE: See under *R. minus*.

DISEASES AND INSECTS: See under *R. minus*.

LANDSCAPE VALUE: Very handsome and aesthetic broadleaf evergreen; the flowers are beautiful but the foliage is equally valuable; beautiful when used in mass; hardy to about -20°F with proper cultivar selection.

CULTIVARS: Several are not *R. catawbiense* hybrids but are included here for convenience.

'A. Bedford'—Lavender-blue with dark blotch, -15°F.

'Albert Schweitzer'—Award winner from Holland noted for its large, conical trusses of pink flowers enhanced by a striking red flare; upright, vigorous habit.

'Album' (var. *album*)—A plant of great hardiness and vigor with buds flushed lilac, opening to pure white flowers with greenish yellow spotting, held in compact, rounded trusses; 6' high, -25°F, excellent lustrous dark green foliage.

'Album Elegans'—White, -15°F.

'Alice'—Deep pink, -15°F.

'America'—Brilliant deep red, very floriferous, forming a broad bush, not as hardy as 'Nova Zembla', -15 to -20°F.

'Anah Kruschke' (*R. griersonianum* × *R. ponticum*)—Dense plant, glossy foliage, deep purple flowers form a tight truss, performed well in University's Botanical Garden, -15°F.

'Anna Baldisiefen'—Star shaped ruffled flowers are light rose with darker midribs and edges, upright growing, to 3'.

'Anna Rose Whitney' (*R. griersonianum* × 'Countess of Derby')—This huge plant is impressive with its large full truss of deep rose-pink flowers with very light spotting on the upper lobes, -15°F.

'Antoon Van Welie'—Deep pink with a lighter blotch, -15°F.

'Autumn Gold'—Apricot-salmon.

'Baden Baden'—Red.

'Betty Wormald'—Pink with light center.

'Blue Diamond'—Lavender-blue.

'Blue Ensign'—Lavender-blue with a prominent dark blotch held in a rounded truss, the leaves are large and dark matte green, smaller than 'Blue Peter', 4 to 5' high, -15°F.

'Blue Jay'—Lavender-blue with brown blotch, -15°F.

'Blue Peter'—The flowers are a light lavender-blue with a striking purple flare, the leaves are dark green and glossy, 5 to 6' high, -15°F.

'Boursault'—Lavender flowers in a rounded truss, good sturdy habit, 5' high, -25°F.

'Bow Bells'—Bright pink, -15°F.

'Butterfly'—Pale yellow, -15°F.

'Calsap'—Pale lavender buds open to white with a dark red blotch, hardier than 'Sappho'; wider than high.

'Caractacus'—Red, -15°F.

'Caroline'—These pale lavender-pink flowers have a fragrance enhanced by the warmth of the sun; highly resistant to root disease, 6' high, -15°F.

- 'Cary Ann'—Coral-red, -15°F .
- 'Cheer' ('Cunningham's White' $\times$ red *R. catawbiense* hybrid)—Shell-pink flowers have conspicuous red blotches in conical trusses, the plant is rounded and compact with glossy leaves, 5' high, -15°F , flowers early in University's Botanical Garden, often flowers in fall.
- 'Chionoides'—White flowers have the yellow centers and make numerous dome shaped trusses. The broad, dense plant is easy to grow and has attractive, narrow foliage, 4' high, -20°F .
- 'Christmas Cheer'—Light pink, -20°F .
- 'Cilpinense'—Apple blossom pink, -20°F .
- 'Compactum'—This form stays less than 3' tall.
- 'Cosmopolitan'—Pink with a red blotch, -20°F .
- 'Cunningham's Blush'—Blush-pink petals with light pink blotch, dark green leaves on this small shrub with a compact habit, -20°F .
- 'Cunningham's White'—Pink blushed buds open to white flowers blotched with greenish yellow, excellent foliage, low compact growth, -20°F .
- 'Cynthia' (*R. catawbiense* $\times$ *R. griffithianum*)—Showy conical trusses of rosy crimson flowers with blackish crimson markings, large and vigorous, 6' tall, rather rank growing, -15°F .
- 'Daphnoides'—Purple.
- 'Dora Amateis'—Floriferous white flowers, lightly spotted with green, slightly aromatic, vigorous, 3' high, twice as wide as tall, deep green dense foliage, -15°F .
- 'Dr. V. H. Rutgers'—Aniline red, a compact grower with good flowering capabilities, -20°F .
- 'Edward S. Rand'—Crimson-red with a bronze eye, -20°F .
- 'Elisabeth Hobbie'—Red, semi-dwarf, -20°F .
- 'English Roseum'—Light rose, vigorous yet compact, upright plant, large foliage, good growing habit, heat tolerant, -25°F .
- 'Evening Glow'—Light yellow, -15°F .
- 'Everestianum'—Rosy lilac, -20°F .
- 'Fastuosum Flore Pleno' ('Fastuosum Plenum')—Lavender-blue, semi-double, -20°F .
- 'Fred Hamilton'—Yellow with pink bands, -15°F .
- 'Furnivall's Daughter'—Pink with a sienna blotch, -20°F .
- 'Gomer Waterer'—Buds are slightly rose tinged, opening to white, dark green glossy leaves, broad and upright, 6' high, -15°F .
- 'Good News'—Crimson-red, -15°F .
- 'Grandiflorum'—Lilac, -20°F .
- 'Griersplendour'—Plum, -15°F .
- 'Halfden Lem'—Large, crimson trusses and heavy-textured, deep green foliage, a good grower and improvement over 'Jean Marie Montague', -5°F .
- 'Harvest Moon'—Pale yellow with red spots, -15°F .
- 'Hellakki'—5 to 6' by 5 to 6'; dark violet-red; Zone 4 to 7; -29°F flower buds.
- 'Henrietta Sargent'—Tall growing, hardy, deep rose-pink flowers.
- 'Ignatius Sargent'—Deep rose, -25°F .
- 'Jean Marie De Montague'—Bright scarlet flowers, dark green foliage, compact habit, -15°F .
- 'Jock'—Rosy pink, -15°F .
- 'Kluis Sensation'—Dark red, -15°F .
- 'Labar's White'—Pure white flowers with yellow-green spotting in the throat, from Labar's Nursery, exceptional heat and cold tolerance.
- 'Lady C. Mitford'—Peach pink, -15°F .
- 'Lavender Queen'—Lavender, -20°F .
- 'Lee's Best Purple'—Purple flowers in June, excellent, smooth, dark foliage, hardy to -20°F .
- 'Lee's Dark Purple'—Buds very dark purple, opening to dark purple, surrounded by wavy foliage, grows into a broad compact bush, common in the nursery trade, -20°F .
- 'Lemon Ice'—Yellow, -20°F .
- 'Loder's White'—White, -15°F .
- 'Lord Roberts'—Red with a dark blotch, -20°F .
- 'Madame Carvalho'—White with green spots, -20°F .
- 'Madame Cochet'—Purple with a white center, -15°F .
- 'Madame Masson'—White with a yellow blotch, -20°F .
- 'Marchioness of Lansdowne'—Rose, -20°F .
- 'Mary Belle'—Light salmon buds open to peach, -20°F .
- 'Michael Waterer'—Dark red, -20°F .
- 'Mikkeli'—5 to 6'; white with green flecks; -34°F .
- 'Moonglow'—Extremely good grower with light pink flowers becoming white when fully opened; pink dots in throat with pink anther and stamens; an improved 'Pink Pearl' type, hardy to 0°F .
- 'Mother of Pearl'—White, -15°F .

- 'Mrs. Betty Robertson'—Creamy yellow with red spots, -15°F .
 'Mrs. C.S. Sargent'—Rich carmine-rose flowers, spotted yellow, a worthy selection for cold areas.
 'Mrs. E.C. Stirling'—Silvery pink, -15°F .
 'Mrs. Lady de Rothschild'—White, flushed pink, -15°F .
 'Mrs. T.H. Lowinsky'—White with a reddish brown blotch, -20°F .
 'Myrtifolium'—Medium pink, small, -20°F .
 'Nepal'—Pure white flowers, dark green wavy leaves, -25°F .
 'Nova Zembla'—Red flowers, perhaps not as intense and with more lavender than 'America', quite cold tolerant and heat resistant, probably one of the best for the Midwest and does well in the South, -25°F .
 'Old Port'—Medium purple with a dark blotch, -20°F .
 'Parson's Gloriosum'—Compact, conical trusses of lavender flowers, compact yet tall growth habit, dense, dark green foliage, -25°F .
 'Pearce's American Beauty'—Olive yellow spots on a dark rose red flower, mid-season, handsome dark foliage that resembles 'Scintillation', tight grower to 6'.
 'Peter Tigerstedt'—6' by 6'; white with violet flecks; Zone 4 to 7; -33°F .
 'Pink Pearl'—Soft rose-pink, -15°F .
 'Pink Petticoats'—China rose, -15°F .
 'Pink Twins'—Light shrimp-pink, -20°F .
 'Polarnacht'—Rich, deep dark purple flowers with spotted, red throats, in trusses of 12 to 14, subtended by dark green leaves; 3' by 6'; Zone 6 from H. Hachmann Nursery, Barmstedt, Germany.
 'Powell Glass'—White-flowering, wide, upright and vigorous.
 'President Lincoln'—Lavender-pink with a bronze blotch, -25°F .
 'Prince Camille de Rohan'—Light pink, -20°F .
 'Purple Lace'—Lacy purple with a light center, -15°F .
 'Purple Splendour'—Dark purple with a black blotch.
 'Purple Splendour Compacta'—A more compact sport of 'Purple Splendour', slightly smaller flower.
 'Purpureum Elegans'—Bishop's violet, dark green foliage, fine compact shape and the flowers open a clear pure color, -25°F .
 'Purpureum Grandiflorum'—Medium-dark purple flowers, somewhat later than typical large-leaf rhododendrons, slightly slower growing than average.
 'Rosamundi'—Light pink flowers in profusion, showy, small mounded shrub, -15°F .
 'Roseum Elegans'—The old stand-by, lavender-pink (rosy purple) flowers and reliability in flowering, withstanding temperature extremes without injury, more than one form under this name, -25°F , excellent heat tolerance.
 'Roseum Pink'—Clear pale pink, similar to 'English Roseum', strong grower making a broad well-filled plant, -25°F .
 'Roseum Superbum'—Rose lilac, -25°F .
 'Roseum Two'—Pink, a strong grower with excellent bud set capabilities, bud sport in Wells Nursery.
 'Sappho'—Mauve buds open to pure white flowers with a conspicuous blotch of violet overlaid with blackish purple, the plant habit is open and rather leggy, good background plant, 6 to 10' high, -10°F .
 'Scarlet Wonder'—Scarlet-red, -20°F .
 'Shamrock'—Chartreuse flowers, extremely compact form, wider than high, -25°F .
 'Sham's Candy'—Bright pink with yellow-green blotch, -25°F .
 'Spitfire'—Deep red with brown blotch, -20°F .
 'The General'—Crimson with dark red blotch, -25°F .
 'Top Gun'—Compact habit, pinkish purple flowers, vigorous, sport of 'Anah Kruschke'.
 'Trilby'—Deep crimson flowers with black blotches, small shrub with distinctive red stems, -20°F .
 'Trocadero'—Large, bright red inflorescences, later than most, dark green foliage; 3' by 4' in 10 years; Zone (5)6; 'Torero' $\times$ 'Erato'; from H. Hachmann Nursery, Barmstedt, Germany.
 'Trude Webster'—Rich pink with dark spots, -15°F .
 'Unique'—Reddish buds open to peach tinged yellow flowers, small, compact, mounded form, -15°F .
 'Virginia Richards'—Large trusses open pale yellow with pink overtone, becoming deeper yellow with crimson blotch, small, compact shrub, -15°F .
 'Vivacious'—Hardy, compact and clearer red than 'Nova Zembla', introduced by Vineland Experimental Station in Canada.
 'Vulcan'—Heavy trusses of brick red flowers, small, compact shrub with excellent mounded form, -20°F .
 'Vulcan's Flame'—Bright red, -20°F .
 'Wilgen's Ruby'—Red with brown blotch, -20°F .

PROPAGATION: Seed requires no pretreatment; cuttings show great variation in rootability. I have had good success rooting various Catawba types by collecting cuttings in mid-August, wounding for about 1 to 1 1/2", cutting leaf surface in half, treating with 1,000 to 10,000 ppm IBA/50% alcohol for 5 seconds and placing the cuttings in peat:perlite under mist; rooting takes place in 2 to 4 months. A protocol that produced

outstanding results in our shop included firm July–August cuttings, two-sided wound, 10,000 ppm KIBA quick dip, followed by 8,000 ppm IBA-talc, 3 perlite:1 peat, mist, with excellent rooting in about 10 weeks. A respectable paper, *Proc. Intl. Plant Prop. Soc.* 43:178–182 (1993) discusses *Rhododendron* propagation in the Pacific Northwest. Brigg's Nursery, Olympia, WA produces 99% of the rhododendrons via tissue culture. In contrast, Van Veen Nursery produced over 400 cultivars from cuttings with 291,000 rooted in 1991–1992.

ADDITIONAL NOTES: One of the hardiest and best known of all the rhododendrons. On the trail to the summit of Rabun Bald, a 15' high specimen literally paves part of the path with rose-purple petals in mid to late June. Always gratifying and inspirational to experience the beauty. To think that the plant breeders utilized this species to develop the truly iron-clad cultivars . . . well something short of a miracle.

NATIVE HABITAT: Alleghenies, West Virginia, southwest to Georgia and Alabama. Introduced 1809.

Rhododendron groenlandicum (Oeder.) Kron & Judd (formerly *Ledum groenlandicum* Oeder.) — Labrador Tea

(rō-dō-den'dron green-land'i-kum)

FAMILY: Ericaceae

LEAVES: Alternate, simple, evergreen, 3/4 to 2" long, 1/4 to 1/2" wide, elliptic or ovate to oblong, obtuse, margins recurved, glaucous and resinous, dark green above, covered with dark brown rust beneath, fragrant when crushed; petiole—1/6 to 1/4" long.

BUDS: Solitary, sessile, somewhat compressed, small with about 3 exposed scales; the terminal flower buds large, round or ovoid, with some 10 broad mucronate, glandular-dotted scales.

STEM: Slender, rounded, young shoots densely covered with rusty tomentum; older branches reddish brown or copper-colored; pith—small, somewhat 3-sided, spongy, brownish; leaf scars—mostly low, half-elliptical or bluntly cordate, the lowest transversely linear; 1 bundle trace.

SIZE: 2 to 4' in height by 2 to 4' in spread.

HARDINESS: Zone 2 to 5.

HABIT: Dwarf evergreen shrub with erect branches forming a rounded mass, sometimes procumbent.

RATE: Slow.

TEXTURE: Medium-fine in all seasons.

LEAF COLOR: Deep dark green above, undersides covered with whitish or rusty brown hairs.

FLOWERS: Perfect, white, each flower 1/2 to 3/4" across, borne in 2" diameter corymbs from May through June.

FRUIT: Capsule, about 1/5" long, not showy, 5-valved, opening from base to apex.

CULTURE: Transplants readily, fibrous rooted; prefers moist, sandy, peaty soils; found in swampy moors of northern latitudes; full sun or partial shade.

DISEASES AND INSECTS: Anthracnose, leaf galls caused by fungi, rusts and leaf spots.

LANDSCAPE VALUE: Another interesting and little known ericaceous plant which is good for cool, moist, swampy areas; the plants I have seen were attractive in flower.

CULTIVARS:

'Compactum'—Dense, neat shrub to 1' in height with short branches, very woolly stems, short broad leaves, and small flower clusters.

PROPAGATION: Seeds can be grown as described for *Calluna*; layers and cuttings can also be used; cuttings collected in October rooted 66 to 100% when treated with 8,000 ppm IBA-talc.

NATIVE HABITAT: Greenland to Alberta and Washington, south to Pennsylvania and Wisconsin. Introduced 1763.

RELATED SPECIES:

Rhododendron neoglandulosum Harmaja (formerly *Ledum glandulosum* Nutt.), (rō-dō-den'dron nē-ō-glandū-lō'sum), Trapper's Tea, Mt. Labrador Tea, grows 20 to 60" high with dark green, 1/2 to 2 1/4" long leaves and white flowers in 2" diameter corymbs. Western North America.

Zone 5. Also found in the northern United States and Europe is ***Rhododendron tomentosum*** Harmaja (formerly *Ledum palustre* L.) (rō-dō-den'dron tō-men-tō'sum), Crystal Tea, Wild Rosemary, which grows 1 to 4' high with 1/2 to 2" long, 1/16 to 1/2" wide, linear to elliptic-oblong, revolute, dull dark green leaves that are rusty pubescent beneath. Both species require cold moist soils for successful culture.

Rhododendron neoglandulosum

Rhododendron minus Michx. (formerly *Rhododendron carolinianum* Rehd.)— Piedmont
Rhododendron

(rō-dō-den'dron mī'nus)

LEAVES: Alternate, simple, evergreen, elliptic to narrow-elliptic, 2 to 3" long, 1/2 to 1 3/4" wide, acutish or abruptly short-acuminate, broad cuneate, dark green and glabrous above, entire, ferrugineous scaly often very densely so beneath, sometimes glaucescent; petiole—1/4 to 1/2" long; leaves aromatic when bruised.

STEM: Glabrous, often deep red to purplish red.

SIZE: 3 to 6' in height with a similar or greater spread.

HARDINESS: Zone (4)5 to 7(8).

HABIT: Small, rounded evergreen shrub of rather gentle proportions; not as coarse as Catawba hybrids, often loose and open, particularly in the wild.

RATE: Slow, 3 to 5' over a 10-year period.

TEXTURE: Medium in all seasons.

LEAF COLOR: Dark green in summer, usually assuming a purplish tinge in cold climates; may remain green.

FLOWERS: Perfect, varies from pure white to pale rose, rose and lilac-rose in color; borne in a terminal, 4- to 10-flowered, umbel-like, 3" diameter raceme (truss), May, corolla 5-lobed, about 1 1/2" wide; full flower June 29, 2008 on Whiteside Mountain between Highlands and Cashiers, NC; have also observed in flower on April 29, 2006 at Highlands Botanical Garden.

FRUIT: Dehiscent 5-valved capsule, best to remove after flowers have faded.

CULTURE: Having tracked rhododendrons and azaleas from the Midwest to East Coast to the southeastern United States, I can unequivocally state that inadequate drainage is the most prominent factor limiting growth. If poor drainage does not directly kill plants, it predisposes them to insects and diseases such as root rot. They have fine silk-like roots, generally without root hairs, and are easy to transplant balled and burlapped or from a container; the root mass is usually profuse, which allows for successful planting; numerous plants are container-grown and the roots form a web (almost fabric-like) at the interface of the medium/container; if plants are left in the containers too long the root mass is so thick and matted it must be cut; ideally make vertical slits with a knife; this will insure contact with the soil when planted and, hopefully, root penetration into the native soil; I have observed azaleas and rhododendrons newly transplanted into a landscape that were wilted or dead; a simple tug on the plant and removal from the ground showed the plant was removed from the container and planted as a solid mass; water uptake was severely limited as the planting hole became dry; I suspect more one gallon azaleas die this way than any other cause. Provide light shade in the North, even heavier shade in the South; have noticed tremendous lacebug infestations on plants exposed to full sun; the State Botanical Garden had a fine collection of ironclad *R. catawbiense* hybrids that were planted on a slope with the root balls above the soil and covered with pine bark; over the years they prospered, but received fertilizer and water as well as an occasional insect spray. This wonderful collection was largely untended and *all* died. With the significant droughts experienced in the Southeast in the past decade, without supplemental irrigation, these plants were doomed. Rhododendrons are extremely sensitive to salinity, high pH (chlorosis), and winter injury.

With emphasis, I recommend gardeners contact their local Extension offices for state or regional guides to the best rhododendrons and azaleas. Almost all states produce some type of guide. Be aware that many rhododendrons are grown in the Pacific Northwest and shipped East. The cultivars may or may not be adapted. Do your homework!

DISEASES AND INSECTS: Botryosphaeria canker, crown rot, dieback, damping-off, azalea petal blight, azalea gall, leaf spots, leaf scorch, powdery mildew, rust, shoot blight, shoestring root rot, wilt, rhododendron aphid, azalea stem borer, azalea leaf tier, black vine and strawberry weevils, giant hornet, Japanese beetle, asiatic garden beetle, lace bugs (in the Southeast, lace bugs are terrific problems with the small leaf evergreen azaleas, although they appear to infest any plant with the generic name of *Rhododendron*; Dr. S. Kristine Braman, Entomology, University of Georgia, has an active program to determine resistance, et al.; *J. Environ. Hort.* 10(1):40-43 (1992) discusses resistance in deciduous azaleas); red-banded leafhopper, azalea leaf miner, rhododendron tip midge, mites, mealybugs, pitted ambrosia beetle, rhododendron borer, scales, thrips, rhododendron whitefly, nematodes, stem girdling caused by woodpeckers. Rhododendrons are troubled by many pests and their culture is often fraught with difficulty. Good cultural practices will reduce the incidence of disease and insect damage.

LANDSCAPE VALUE: Like all rhododendrons a nice plant for the shrub border, groupings, massing, foundations; should be sited in a slightly shaded area and out of strong winter sun and wind; survived -20°F in our Illinois garden and flowered nicely.

CULTIVARS:

'Album'—White flowers.

'Carolina Gold'—A yellow flower color is brought to this species by Dr. August E. Kehr; dark shiny leaves, upright growing habit.

'Luteum'—Mimosa-yellow flowers.

'White Perfection'—Compact habit, soft pink buds open to pure white flowers, shiny deep green foliage.

PROPAGATION: See under *Calluna*; I have raised many seedlings with a minimum of effort. Like most rhododendrons this species exhibits great variation when grown from seed. Cuttings are somewhat difficult to root but when taken in August and treated with a hormone and fungicide will give a reasonable percentage.

NATIVE HABITAT: Blue Ridge Mountains of Carolinas and Tennessee. Cultivated 1815.

RELATED SPECIES: Considerable upheaval in *Rhododendron* nomenclature and taxonomy since the 1998 edition. What was *R. carolinianum* is now called Carolinianum Group (see comment in *Manual* Nomenclature and Taxonomy section). In truth, I could not reliably identify *R. carolinianum* and *R. minus* in the wild. Observed the complex countless times in the southern Appalachians.

Rhododendron minus Michx. var. ***chapmanii*** (A. Gray) W.H. Duncan & Pullen, (formerly *R. chapmanii* A. Gray) (rō-dō-den'dron mī'nus chap-man'ē-ī)

Rhododendron minus var. *chapmanii* is an erect growing, lumpy, irregular, 6 to 10' high, evergreen shrub. The oblong to oval, 1 to 2" long, dark green leaves have an obtuse apex and revolute margin with a 1/4" long petiole. The rose-pink, funnellform flowers with chocolate-colored anthers appear in spring, typically April–May. Have observed plants in flower in October at Charles Webb's wonderful garden outside of Lee, FL. Would make sense to utilize the species for breeding heat tolerance. Western Florida. Introduced 1936. Zone (6)7 to 9.

Cultivars include:

White—White flowers in spring, 10'.

'Wonder'—Lavender-pink flowers, early to mid-season; rapid-growing, 4';–15°F hardiness.

Rhododendron minus var. *chapmanii* × *R. dauricum* var. *album*—Bright lavender pink flowers; 4 to 5'; tolerates summer heat.

Rhododendron mucronulatum Turcz. — Korean Rhododendron

(rō-dō-den'dron mū-kron-ū-lā'tum)

LEAVES: Alternate, simple, deciduous, elliptic to elliptic-lanceolate, 1 to 4" long, 1/2 to 1 1/4" wide, acute or obtusish, medium green, entire, very aromatic when crushed, thin textured; petiole—1/8 to 1/4" long.

BUDS: Flower-rounded-ovoid, light brown, glabrous.

STEM: Slender, light straw-brown.

SIZE: 4 to 8' in height with a similar spread.

HARDINESS: Zone 4 to 7.

HABIT: Deciduous shrub of upright-oval to rounded outline with clean branching and foliage characteristics.

RATE: Slow, perhaps medium in youth.

TEXTURE: Medium-fine in foliage, medium in winter.

LEAF COLOR: Soft green in summer changing to shades of yellow and bronzy crimson in fall.

FLOWERS: Bright rosy purple, 1 1/2" long and 1 1/2" wide, mid to late March to early April, 3 to 6 together at the ends of the branches; flowers well before the leaves and often as the buds are opening a freeze will kill or injure them; siting is very important and a protected location where the south and southwestern sun will not hit them in February and March is recommended.

CULTURE: Trouble free plant, one of the hardiest.

DISEASES AND INSECTS: See under *R. minus*.

LANDSCAPE VALUE: First of all the hardy rhododendrons and azaleas to flower in northeastern United States; very lovely in a shrub border; I had 5 scattered around the northeast corner of our Illinois home and they made nice foundation plants because of compactness and good foliage as well as lovely early flower.

CULTIVARS:

'Album'—White form, with just a hint of pink, early-flowering.

'Bright Pink'—Pink flowers that are a bit brighter than 'Cornell Pink', late April.

'Cama'—Large soft flowers that fade to white, unusual semi-evergreen leaves.

'Cornell Pink'—Phlox pink flowers, unadulterated by the magenta present in the flowers of the species; raised by Henry T. Skinner, Cornell University; named and put in commerce in 1952.

'Crater'(s) Edge'—A true dwarf, dark red buds open lavender-pink.

Dwarf Form—Intense lavender flowers, low and mounded to less than 3', bright fall color.

'Easter Bunny'—Soft lavender with a light cream to light yellow flare, mid-April.

'Mahogany Red'—Bright red flowers; Dr. August Kehr selection.

'Nana'—Clear purple flowers, dwarf to 2', mahogany fall color.

'Pink Mucronulatum'—Lovely shades of pink, occurs in seed produced populations.

'Pink Peignoir'—Soft pink clone, opens early April, at least two week earlier than 'P.J.M.', opens and remains an unusually soft shade of pink that blends particularly well with the typical lavender color of the species, more subtle in the landscape than brighter pink clones such as 'Salem Hill Pink' and 'Cornell Pink', should be hardy to -25°F, 6' in 20 years.

'Radiant Pink'—Bright fluorescent pink flowers, warm, yellow-bronzy fall color; upright habit.

'Winter Brightness'—Rich purplish rose flowers.

PROPAGATION: Seed, very easy; softwood cuttings collected in July rooted 50%. I have grown many seedlings of this species and also rooted many cuttings. One of the seedlings flowered in spring of 1975 and was a beautiful soft pink (apple blossom-like).

NATIVE HABITAT: Northern China, Manchuria, Mongolia, Korea and northern Japan. Introduced 1882.

Rhododendron schlippenbachii Maxim. — Royal Azalea

(rō-dō-den'dron shlip-en-bak'ē-i)

LEAVES: Alternate, simple, usually 5 at ends of the branches, appear as if whorled, short-petioled, obovate or broad-obovate, 2 to 5 1/2" long, 1 1/2 to 3" wide, truncate or rounded to emarginate at apex, mucronate, cuneate, slightly undulate, sparingly pubescent when young, later glabrous except on veins beneath, dark green above, pale beneath.

SIZE: 6 to 8' high and as wide at maturity, can grow larger but this seldom occurs in the United States.

HARDINESS: Zone 4 to 6, best in colder climates, I have tried it several times in Zone 7 with no success.

HABIT: Upright-rounded deciduous shrub.

RATE: Slow.

TEXTURE: Medium in all seasons.

LEAF COLOR: Leaves with purplish red suffusion, dark green in summer, yellow, orange, crimson in fall.

FLOWERS: Pale to rose-pink, no trace of magenta, fragrant, appearing before or with the leaves, early to mid-May; 3 to 6 together in a 2 1/4 to 3" diameter inflorescence; one of the most delicate and beautiful of the azaleas for northern gardens; 10 stamens.

CULTURE: Seems to do better on high pH soils than other Ericaceae; pH 6.5 to 7 would be acceptable; may have a higher calcium requirement than other types.

LANDSCAPE VALUE: One of the finest azaleas, flowers open just as the leaves are expanding; no adequate way to do justice to the beauty of this plant by the written word.

CULTIVARS:

'Sid's Royal Pink'—Deeper pink, 3" diameter flowers, 3 to 5' high, brilliant fall color.

PROPAGATION: Seed as previously described. Cuttings taken in late May and treated with a hormone (IBA) will give a fair percentage.

ADDITIONAL NOTES: This species comes fairly true from seed as it fails to hybridize freely with other species.

NATIVE HABITAT: Korea, Manchuria, eastern Russia near Vladivostok. Introduced 1893.

Other Rhododendrons and Azaleas

Rhododendron alabamense Rehd. — Alabama Azalea

(rō-dō-den'dron al-a-bam-en'sē)

Rhododendron alabamense is a deciduous shrub growing 5 to 6'(8') high. It tends toward compactness and may sucker. Colonies of 5 to 6 acres are known. The white, yellow-blotched (not always present), exceedingly fragrant flowers appear with the new leaves in mid to late April (Athens). April 27, 2004 full flower at Keith Arboretum, Chapel Hill. They occur 6 to 10 together in a terminal cluster. The 5 stamens are about twice as long as the 1 1/2 to 2" long, tubular, funnel-shaped corolla. Flowers with the leaves. This

is a beautiful plant in flower. Possibly the most fragrant of the native azaleas. An 8 to 10' high and wide specimen at Biltmore House and Gardens is magnificent. Does not always appear true-to-type and should be purchased in flower. Great "doer" in the Dirr garden and flowers after *R. austrinum*, *R. canescens*, and *R. flammeum*. Possibly the most fragrant of the native azaleas. 'Caroline Dean' and 'Thomasville' have fragrant, white flowers, 10' high. Found in dry open woodlands and rocky hill sites in north central Alabama and isolated areas in west central Georgia. Introduced 1922. Zone (6)7 to 8.

Rhododendron arborescens (Pursh.) Torr. — Sweet Azalea
(rō-dō-den'dron ār-bō-res'enz)

Rhododendron arborescens is a deciduous, erect-stemmed, loosely branched shrub growing from 8 to 20' in height with an equal spread. Foliage is lustrous dark green in summer and turns reddish in fall. Flowers are white to light pink with a reddish style and pinkish to rose filaments, 1 1/2 to 2" long, after the leaves in May, June-July, fragrant odor like heliotrope. Best native white azalea that is hardy in the North. Prefers light, consistently moist, acid soil. Specialty growers offer pink, rose, smoky pink and yellow forms; also 'Hot Ginger' and 'Dynamite' selected for white flowers, pink stamens and intense fragrance; grew 6' by 5' in 18 years. 'White Lightning' is Clarence Towe's vigorous, white-flowered clone. The more I study the native azaleas the more convinced I become of their similarities. Have observed this species on high mountains, 4,000 to 5,000' altitude, in Georgia and North Carolina. Flower colors are rose, pink, white, and various shadings. Beautiful, delicate, and refined. Native from southern Pennsylvania to Georgia and Alabama; grows chiefly on the banks of mountain streams although I have observed it in many different cultural niches. Introduced before 1814. Zone 4 to 7.

Rhododendron atlanticum (Ashe) Rehd. — Coast Azalea
(rō-dō-den'dron at-lan'ti-kum)

Rhododendron atlanticum makes a rather handsome 3 to 6' high and wide shrub of suckering habit. The leaves are a distinct bluish green and offer a handsome color contrast. The fragrant pinkish white (white to pink) flowers occur with or slightly before the leaves in April. Each flower is 1 to 1 1/2" long and about 1 1/4 to 1 1/2" wide with the stamens twice the length of the corolla. Corolla is covered with sticky glands and can be easily identified by this trait coupled with distinct foliage and later flowering. This is a beautiful azalea but like many of the natives it does not have the blatant flair of the evergreen hybrids. I have had good success rooting it from softwood cuttings. Used as a parent along with *R. periclymenoides* in the Choptank Hybrids. They are natural hybrids found wild in the vicinity of the Choptank River, Maryland, by Mr. and Mrs. Julian Hill. Several selections are apparently seedlings from the original wild selected plants. A hybrid, *Rhododendron atlanticum* × *R. austrinum*, has fragrant, orange-yellow flowers, early season. Found in the Coastal Plain from Delaware to South Carolina often in open pine woods. Introduced about 1916. Zone 5 to 8(9).

Cultivars include:

- 'Choptank Blend'—A scrumptious blend of cream, rose and yellow makes a charming flower, full and tall.
- 'Choptank C-1'—Mrs. Julian Hill found this group of plants with delicate fragrant white flowers that perfume the garden, stoloniferous.
- 'Choptank Mellow'—Soft yellow flowers with lavender markings.
- 'Choptank River'—Natural hybrid with *R. periclymenoides*, same intense lovely scent as *R. atlanticum* but usually a tad pinker, late May into June.
- 'Choptank River Belle'—Pink buds open to very fragrant white flowers flushed with pink, pink stamens, lovely blue-green foliage.
- 'Choptank Rose'—A fragrant rose and white flower with a golden blotch, plant is large and flowers are of good texture and fragrance.
- 'Choptank Yellow'—This offspring of 'C-1' is yellow with a slightly golden shading on the upper lobe, fragrant and hummingbirds flock to it.
- 'Choptank Yellow and Orange'—The yellow and orange colors mix and mingle in this huge ball truss, fragrant.
- 'Marydel'—Deep pink buds, white flowers with a touch of pink, very fragrant, Polly Hill's selected clone.
- 'Nacoochee'—A selected Choptank seedling that has a fragrant white flower with a touch of pale pink.
- 'Pink Choptank'—A clear pink flower adorns this large plant which is an offspring of a selfed cross made years ago by the late George Beasley, Transplant Nursery, Lavonia, GA.
- 'Snowbird'—Intensely fragrant white flowers nestle in rich blue-green foliage; see this more frequently in commerce; have savored the fragrance; in my opinion, not great degrees better than everyday *R. atlanticum*; considered a *R. atlanticum* × *R. canescens* hybrid; I see little of the latter in this cultivar; originated at Biltmore Estate.
- 'Twiggy'—A descriptive name for a small, almost miniature plant that has white, fragrant flowers, a Choptank seedling.
- 'Winterthur'—A superior compact white selection, not stoloniferous.
- 'Yellow Delight'—A choice seedling from an open pollinated *R. atlanticum*, large soft yellow with great fragrance and good growth habit.

Rhododendron austrinum (Small) Rehd. — Florida Azalea
(rō-dō-den'dron aw-strī'num)

Rhododendron austrinum grows 8 to 10' high and forms a rather loose multi-stemmed shrub. The fragrant, clear yellow, cream, orange to almost pure red flowers occur 8 to 15 together, April–May. Flowered in our garden during mid-April; flowers before and with emerging leaves; colors are variable as mentioned. Each flower is 3/4" long and the tube somewhat cylindrical with 2" long stamens. Again, this is a most beautiful native plant that makes a splendid addition to the shrub border. Over the years, Bonnie and I have accumulated 15 different seedlings with a color range of soft yellow to orange, some trusses are almost ball-shaped and flowers are outstandingly fragrant. One of the easiest natives to grow; requires no pampering. Northern and western Florida to southwest Georgia, southern Alabama and southeastern Mississippi. Introduced 1914. Zone (6)7 to 9.

Cultivars include:

- 'Adam's Orange'—Brightly colored deep orange selection.
- 'Alba'—A white-flowered form, selected by Steve Riefler in northwest Florida.
- 'Austrinum Gold'—Early opening, bright gold, fragrant flowers, plant grows as wide as tall.
- 'Clyde's Yellow'—Huge clusters of beautiful, large, bright yellow flowers in the spring.
- 'Coleman's Early Yellow'—Possibly a hybrid with *R. alabamense*, light yellow flowers that appear in April, 1 to 2 weeks earlier than the flowers of *R. austrinum*.
- 'Don's Variegated'—Strong orange flowers; leaves variegated and speckled cream and green; reasonably prominent variegation, quite stable, to my knowledge not many variegated forms of azaleas, particularly the deciduous.
- 'Escatawpa'—Brilliant yellow-orange flowers, vigorous grower, terrific performer in Dirr garden, from the Escatawpa River area of Alabama.
- 'Harrison's Red'—A coral-colored (rosy red) selection found near Chipley, FL.
- 'Henry Foundation'—Fragrant yellow flowers, 12'.
- 'Millie Mac'—The yellow center of each flower is bordered with a distinct white margin, found in Escambia County, AL by Mr. and Mrs. Floyd T. McConnell of Mobile, AL.
- 'My Mary'—Fragrant, ball-shaped trusses of gleaming light yellow flowers with long stamens early in the season, compact growth, thickly textured foliage, named after Mary Beasley, Transplant Nursery.
- 'Mooshatanio'—Dark orange.
- 'Pretty One'—Outstanding, large (2" long), salmon red, fragrant flowers with a yellow blotch, 8 to 10' in height.
- 'Rushin's Austrinum'—Bright yellow flowers with clear yellow tubes herald spring with their aroma.
- 'Taylor Maid'—Orange-yellow flowers.

Rhododendron bakeri (Lemmon & McKay) Hume — Cumberland Azalea
(rō-dō-den'dron bā'kēr-i)

Rhododendron bakeri is allied to *R. calendulaceum* but is more compact and tends to flower 2 or more weeks later. The 1 1/4 to 1 3/4" long flowers are usually a good red but range from (yellow) orange to red. Have seen the species in flower on May 25 at Biltmore. Spectacular in flower. Does not tolerate excessive heat. Will grow 4 to 8' high; tends to be low-growing with somewhat horizontal branches. Similar to *R. calendulaceum* and by some authorities lumped with that species. 'Camp's Red' has red-orange flowers. 'Sunlight' has orange, deep rose, and gold flowers in early summer; dark green foliage; Polly Hill selection. A compact, double, red form is known. *Rhododendron bakeri* × *R. viscosum* has fragrant, pink flowers; late-flowering. Hillier 2002 lists this taxon as *R. ×bakeri* (*R. canescens* × *R. flammeum*). Kentucky, Tennessee, mountains of North Carolina, Georgia, and Alabama. Introduced 1936. Zone 5 to 7.

***Rhododendron* 'Boule de Neige'** is listed as a Caucasian hybrid and is one of the finest white flowering types. The evergreen foliage is a dark, lustrous green and the habit is compact and rounded. Zone 5, possibly 4. Usually described as flower bud hardy to −15°F. As a graduate student at the University of Massachusetts, I was introduced to this taxon by the late Professor Thompson, who literally considered this the best of all rhododendrons for habit (5' by 8'), dark green foliage and large white flower trusses. He considered this the standard by which others should be judged. Interestingly a 1988 article on rhododendrons by Peter Loewer, *Horticulture*, essentially reiterated Professor Thompson's beliefs; for as many rhododendrons that are introduced each year, it is amazing how few really measure up.

Rhododendron calendulaceum (Michx.) Torr. — Flame Azalea
(rō-dō-den'dron ka-len-dū-lā'sē-um)

Rhododendron calendulaceum is a deciduous, loosely branched shrub of upright habit, usually as wide as high (4 to 8' tall by a comparable spread to 10 to 15' high and wide). The summer foliage is medium green and the fall color subdued yellow to red. Flowers average 2" diameter, May–June, late May at 3,600', Rabun County, GA, in loose trusses; colors range from lemon to dark yellows, tawny, apricot, salmon, deep flesh color, pinkish, brilliant shades of orange and scarlet, non-fragrant. Most showy and one of the most notable

American azaleas (a parent of the Ghent hybrid race). Retains flowers for nearly two weeks. Excellent in naturalistic setting or mass planting. Abundant in southern Appalachians in every imaginable color. Could be easy to contract cultivaritis as the range of flower colors, individual flower sizes, inflorescence sizes, habits, and fall colors are across the spectrum. Bonnie and I have photographed many variations along the Blue Ridge Parkway in May–June. Mid May at about 3,000' elevation in southwest Virginia is peak. Absolutely beautiful yellow, orange, red and bicolors. Native to mountains of Pennsylvania south to Georgia. Zone 5 to 7, does not prosper in high heat. Cultivated 1800.

Cultivars include:

Abbott Azaleas (*R. calendulaceum* × *R. prinophyllum*)—Super hardy hybrids created by Frank Abbott of Saxton's River, VT, withstood temperatures to −40°F.

'Carlsons Coral Flameboyant'—Large flowers in a bright shade of coral.

'Chattooga'—Pink, ruffled flowers with a yellow blotch gradually turn soft yellow, natural hybrid of *R. calendulaceum* × *R. periclymenoides*.

'Cherokee'—Soft apricot flowers with red stamens.

'Currahee'—Large shrub with orange flowers bordered with rosy pink, the buds are striped with red and yellow.

'Frank Lunsford'—Fuchsia pink with white coloration, long stamens.

'Golden Sunset Flame'—A blend of orange, gold and yellow colors.

'Golden Yellow Flame'—A large campanulate flower with crimped, pointed tips, the yellow background is accented with gold blotches.

'Lisa's Red Flame'—Large, ruffled, red flower with crimped edges.

'Scarlet Orange Flame'—Glow with its reddish orange flowers.

'Smokey Mountaineer'—Compact form with excellent orange-red flowers and red fall color, handsome planting at Arnold Arboretum.

'Soquee River'—Magnificent truss of orange, red and yellow at the same time, as wide as tall in habit.

'Wahsega'—Dark red form.

'Yellow Flame'—A large, clear bright yellow flower.

Rhododendron canadense (L.) Torr. — Rhodora
(rō-dō-den'dron kan-a-den'sē)

Rhododendron canadense is often a rather scrawny, erect-branched, deciduous shrub that seldom grows more than 3 or 4' high. The leaves are a distinct gray-green and appear after the flowers. The principal beauty lies in the bright rosy purple, 1 to 1 1/2" wide flowers that occur about 6 together at the end of the stem in April. The corolla is quite distinct from other members of the genus in having the 3 upper lobes almost united to the end and erect, the lower 2 narrow-oblong, divided to the base and spreading. There are 10 stamens. It is seldom seen in gardens but makes a lovely splash of color in April. In the wild it is often found in swamps and should be provided moist, acid soil in cultivation. Emerson said of this species, "Beauty is its own excuse for being." Variety *albiflorum* is similar in all aspects to the species form but with pure white flowers and yellowish fall foliage. 'Album' (var. *album*) has a compact, upright bushy habit to 2' with pure white flowers in late spring. The species is native from Newfoundland and Labrador to central New York and Pennsylvania. Introduced before 1756. Zone 2 to ? Requires a cool climate. On a late May day (28th), Bonnie and I were driving to Stonington, ME along Route 15 when, KAWOWIE, a drift of Rhodora in saturated neon rose swept the car into a ditch! Absolutely gorgeous, yet garden fragile. One of nature's best; perhaps best left there. Was growing in water.

Rhododendron canescens (Michx.) Sweet — Piedmont Azalea (also known as Florida Pinxter, Hoary Azalea)
(rō-dō-den'dron ka-nes'enz)

Rhododendron canescens is a large shrub growing 10 to 15' high. The fragrant white to pink to almost rose flowers open in March–mid-April. Each flower is about 1 1/2 to 2" long, funnel-shaped, with sticky glands on outside of corolla. It is native in the Athens area along slopes and stream banks under high shade. There is tremendous variation in corolla color and I have seen forms with white to deep rose-pink flowers. It is stoloniferous and a 10-acre colony has been described. Hybridizes readily with other species. 'Biltmore' is a pure white flowered selection just about full glory on April 24, 2005 at the Raulston. 'Brooke' has fragrant, pink flowers with creamy yellow overtones; vigorous growing and heavy branching. 'Spring Scene' has fragrant, pink flowers in spring; 12'. 'Varnadoes Phlox Pink' has fragrant, tubular, vivid pink flowers in late April; medium-sized habit; somewhat more shade tolerant than other deciduous azaleas; grew in Dirr garden, always reliable. 'Varnadoes Snow' has icy white, tubular, fragrant flowers; medium-sized habit. *Rhododendron canescens* × *R. flammeum* 'Clyo Red' has cherry red flowers. *Rhododendron canescens* is the most abundant species in the Southeast and the range extends from North Carolina, Tennessee to north Florida, Georgia, Alabama and Texas. Introduced around 1730. Zone 5 to 9. Like *R. austrinum*, easy to culture. We grew many seedlings in our Georgia garden.

***Rhododendron colemanii* R. Miller — Red Hills Azalea**
(rō-dō-den'dron cōl-man'ē-ī)

Difficult to accept that another deciduous, native azalea has been identified and documented. Previously confused with *R. alabamense* Rehd. and its hybrids, the new species has been verified by DNA sequences and flow cytometry as a tetraploid (4n). Native distribution is southwestern Alabama to the Chattahoochee Valley in Georgia. Species grows on sandy ridges or banks along creeks or on north-facing bluffs in moist woods. Shrub-like habit, 10 to over 20' high, forming an upright dense outline. Leaves are dull green to glossy green, 2 to 3 1/2" long, 1 to 1 3/4" wide, obovate to oblong. Flowers range from white, pink to yellow, with or without blotches, and open later, typically mid May in the native range. Have only observed a small plant with flowers still in tight bud (pink-white) on May 6, 2009 in Athens. Open flowers range from 1 to 2" wide, to 1" long, with sweet, musky, to lemony fragrance. For detailed history see *J. Amer. Rhodo. Soc.* 62(2):72–78 (2008). Probably Zone 6 to 8(9).

***Rhododendron cumberlandense* E.L. Braun**
(rō-dō-den'dron cum-ber-lan-den'sē)

See comments under *R. bakeri*. I have always been confused between this, *R. bakeri*, and *R. calendulaceum*. Flowers primarily red but varies from yellow, orange to red. Observed the late Polly Hill's 'Sunlight' with orange, deep pink and golden yellow flowers in June in her Martha's Vineyard garden; handsome dark green leaves, rich autumn color. Eastern United States. Zone 5 to 6.

***Rhododendron dauricum* L. — Dahurian Rhododendron**
(rō-dō-den'dron dawr'i-kum)

Rhododendron dauricum is a deciduous to semi-evergreen shrub that matures at about 5 to 6'. The small, 1/2 to 1 1/2" long, 1/4 to 5/8" wide, glossy dark green leaves are rather attractive and assume a purplish tinge in winter. The 1 to 1 1/2" diameter, bright rose-purple flowers appear singly from a cluster of buds at the end of last season's growth in February–March. Sempervirens Group (formerly variety *sempervirens* Sims) is noted for holding the very dark green leaves through the winter. GRIN treats this as *R. ledebourii* Pojark. It flowers in March–April (Boston) and is not particularly showy but does provide a breath of color. It is one of the parents of the 'P.J.M.' rhododendron and has imparted its hardiness to that selection. Mountains of Korea, northern China, eastern Siberia and northern Japan. Cultivated 1780. Zone 4 to 5(6).

Cultivars include:

- 'Adam'—Lavender form that consistently flowers first, a day or so earlier than 'Eve' in early April, colorful orange autumn foliage.
- var. *album*—White flowers, used by Edmund Mezitt in some of the newer compact cold hardy rhododendrons.
- 'April Gem'—Compact, 4' by 4', evergreen plant covered by a profusion of lightly fragrant, double, white, long-lasting flowers, leaves bronze in winter.
- 'April Rose'—Hardy, dense, small-leaved plant, holding many of its deep bronze leaves in winter, bright magenta pink, double flowers, introduced by Dr. Mehlquist.
- 'Hiltingbury'—Evergreen compact habit, leaves bronzing in cold weather.
- 'Madison Snow'—Hardy, semi-evergreen, large, white flowers in early spring, fall color is bright golden, grows to 4'.
- 'Midwinter'—Deciduous to semi-evergreen; flowers phlox-purple.
- 'Snowy Morning Blues'—With pure white flowers that open two weeks later than the species, holds most of the shiny green leaves all winter.

***Rhododendron* 'Exbury' and 'Knap Hill' Hybrids**
are deciduous, upright growing types, 8 to 12' high and 2/3's to as wide, with medium green summer foliage and yellow, orange, red fall colors. Flowers range from pink, creams, yellows, near whites or orange, rose and red, borne in 2 to 5" diameter, 18- to 30-flowered trusses in May.

These hybrids are the result of crosses involving several species including *R. calendulaceum*, *R. arborescens*, *R. occidentale*, *R. molle*. Zone 5 to 7(8). The Exbury types do not display good heat tolerance but southern

Exbury hybrids

breeders have crossed them with native azaleas, particularly *R. austrinum*, and produced heat tolerant lines (see Aromi Hybrids). The Exbury Hybrids as well as the Knap Hill, Ilam, Windsor and Ghent types include a great number of selections. About the only way to find out if they will grow in a given region is to experiment with them. In general they are not suited for Zone 4 (considered flower bud hardy to -20°F , but depends on cultivar) and lower or Zone 8 and higher. Often imbued with mildew that renders them ugly.

EXBURY (EX) AND KNAP HILL (KN) HYBRIDS

- 'Altair'—Large creamy white with yellow flare, very fragrant. (KN)
- 'Anna Pavlova'—Beautiful, ruffled, double, white, fragrant flowers, smaller growing than many of the Knap Hill azaleas and has larger flowers than the well-known 'White Throat'. (KN)
- 'Annabella'—Very fragrant deep golden yellow with dark bronze foliage. (KN)
- 'Anquistas'—Translucent light yellow outlined in pink, lightly fragrant.
- 'Apple Tree Pink'—Large, rounded, pink flowers with subtle yellow markings, mid-season. (EX)
- 'April Surprise'—Yellow-apricot, compact. (EX or KN?)
- 'Arneson Gem'—Large, warm golden flowers edged in bright glowing orange, free-flowering, compact, vigorous. (EX)
- 'Avocet'—Fragrant, white fringed with pink, large, ruffled flowers. (KN)
- 'Ballerina'—A beautiful white with a distinctive yellow center. (EX)
- 'Balzac'—Good red with flame markings on the many, star-shaped, fragrant flowers. (EX)
- 'Banana Split'—Vanilla white surrounding a banana yellow blotch with a cherry throat.
- 'Basilisk'—Pink buds open cream, edged in pink, golden flare. (KN)
- 'Beaulieu'—Salmon pink buds open to a paler shade of pink flowers with an orange flare. (EX)
- 'Berryrose'—Fragrant, orange-red. (KN)
- 'Big Punkin'—Fragrant, huge, round, multi-toned orange and golden trusses appear in mid to late May, lush green new growth, upright plant, -15°F . (EX)
- 'Brazil'—Brilliant tangerine-red, strong grower, buds early, flowers frilled. (KN)
- 'Bullfinch'—Deep red. (KN)
- 'Buzzard'—Fragrant pale yellow, tinged with pink, -24°F flower bud hardiness, vigorous growing, wide upright, resists mildew.
- 'Cannon's Double'—Double pink with light orange shading; mildew resistant, glossy foliage. (EX)
- 'Cecile'—Very large flowers in shades of salmon-pink and yellow, handsome form. (EX)?
- 'Cheerful Giant'—Double, yellow flowers, tips of the petals are slightly orange. (EX)
- 'Clarice'—Pale pink fading to almost white, vigorous upright growth. (EX)
- 'Cockatoo'—Fragrant peach-apricot. (KN)
- 'Colin Kendrick'—Fragrant, pale pink, hose-in-hose flower, truss appears like a beautiful rounded ball of soft cheery pink with a light touch of delicate yellow on the upper petal, good green coloring on the foliage. (KN)
- 'Coquille'—Vivid orange blotch in a bright yellow flower, tall and upright. (EX)
- 'Coronation Lady'—Orange-yellow blotch on the upper petal of the salmon pink flower, new foliage is bronze. (KN)
- 'Corringe'—Fluorescent red-orange with a hot orange flare on the upper petal. (EX)
- 'Crimson'—Crimson-red, robust, upright-growing. (EX)
- 'Dawn's Chorus'—Pink buds open white with rays of dawn's pink. (EX)
- 'Debutante'—Orange blotch on each of the very large, carmine-pink flowers. (KN)
- 'Desert Pink'—Pink. (KN)
- 'Doctor Rudolph Henny'—Buds of reddish orange, flower ages to a fantastic pink with a light touch of yellow on the upper petal, often has 6 petals instead of 5, flower is 4" across, in large trusses of 6 to 10 flowers. (EX)
- 'Double Delight'—Buttercup yellow, very fragrant flowers, floriferous plant. (EX)
- 'Exbury Evening Glow'—Frilled, soft pink tinged with light yellow, golden throat.
- 'Exbury White'—Light cream-yellow buds open to white, star-shaped flowers with a hint of cream throughout, upper petal is graced with a bright bold splash of canary yellow.
- 'Fireball'—Bright shades of orange-red (scarlet), stronger growing plant than most red varieties, foliage is reddish bronze, then dark green when mature. (KN)
- 'Firefly'—Red. (EX)
- 'Fireglow'—Large orange-vermillion flowers, wine-red fall foliage. (KN)
- 'Flamingo'—Frilled fragrant deep pink with orange blotch, upright-growing. (KN)
- 'Fluffy'—Large, frilled flowers open light yellow changing to white with a showy yellow flare, petaloid double form.
- 'Fluorescent Orange'—Fluorescent, bright orange flower, superb rounded trusses.
- 'Frilly Lemon'—Glowing yellow, petaloid double, very frilly, full truss, broad-spreading upright plant, -25°F . (EX)
- 'Gallipoli Red'—Glorious frilled, deep watermelon orange-red flowers, strong growing. (EX)
- 'George Reynolds'—Enormous deep buttery yellow flowers with a deep golden throat. (KN)

- 'Gibraltar'—Spectacular flame-orange flower clusters with ruffled petals, by far the most heat tolerant and vigorous of the Knap Hill group, does well as far south as Zone 7. (KN), often listed as (EX).
- 'Ginger'—Deep orange-carmine buds open to a brilliant orange with a pink flush, deeper pink lines down each petal, fragrant. (EX)
- 'Gold Dust'—Bright deep yellow fragrant flower. (EX)
- 'Golden Dream'—Large open-faced flowers of soft clear yellow. (KN)
- 'Golden Eagle'—Bright orange with a yellowish orange flare. (KN)
- 'Golden Flare'—Vivid yellow with reddish orange blotch, to 2 1/2" diameter. (EX)
- 'Golden Oriole'—Brilliant yellow, deep orange blotch. (KN)
- 'Golden Sunset'—Vivid yellow, wide, upright habit. (KN)
- 'Goldfinch'—Light yellow flowers with a vivid yellow blotch and a hint of orange. (KN)
- 'Harvest Moon'—Pale yellow with a deeper blotch. (KN)
- 'Hawaiian Lei'—Flowers are a deep orange-rose-red with a lighter center punctuated by a showy golden orange flare on the upper petal, often has 6 petals instead of 5.
- 'High Fashion'—Flowers of dusty rose splashed with an orange blotch on the upper lobe. (KN)
- 'High Series'—Snow white flowers with a yellow blotch, kissed with soft pink, large, ball-shaped truss, fragrant. (KN)
- 'Homebush'—Unique rounded trusses of double, deep rose flowers, superb in full flower, vigorous upright shrub. (KN)
- 'Honeysuckle'—Fragrance similar to honeysuckle, pastel pink petals with a yellow-orange flare burning out from the throat, pink on the lower petals change to a soft white giving the whole plant a two-toned effect. (EX)
- 'Hotspur'—Rich red-orange. (EX)
- 'Hotspur Red'—Late flowering, nasturtium red flowers with golden orange throat. (KN)
- 'Hugh Wormald'—Vivid yellow with orange-yellow blotch, wide and upright-growing. (EX)
- 'Iora'—Flower starts out as a creamy peach bud opening to a blend of colors, five-petaled flower flaunts creamy tones which become more peach-pink toward the center of the flower, large yellow flare on the top petal. (KN)
- 'Irene Koster'—Sweetly scented, 2 1/2" diameter, white flowers are flushed with strong pink coloring, medium size when mature. (Occidentale hybrid)
- 'J. Jennings'—Deep orange-red. (KN)
- 'Jackie Parton'—Double and triple buds opening to peach striped orange. (KN)
- 'King Red'—Vivid red, slightly ruffled in a ball-like truss. (EX)
- 'Klondyke'—Large golden orange, young foliage coppery red, wide upright, slow growing. (KN)
- 'Knap Hill Red'—Deep, intense red with bronze-tinted foliage, late May. (KN)
- 'Krakatoa'—Flame red flowers, medium-sized plant. (KN)
- 'Lace Valentine'—Light pink buds open to a brilliant white flower with a yellow blotch, fragrant. (KN)
- 'Lady Roseberry'—Developed by Waterer in 1944, flower is a vivid red. (KN)
- 'Lila'—True white with a large golden flare, buds and petal edges are peach. (KN)
- 'Mandarin Maid'—Large, warm salmon orange flowers with a solid orange-gold flare on the upper petal, wavy petals. (KN)
- 'Mandarin Spiced'—Large, showy trusses of hot orange flowers will often have 6 or more petals which are often twisted on the ends, upper petal has a slight warm orange flare, hardy and vigorous grower.
- 'Marina'—Large, pale creamy yellow flower with a deeper bright yellow blotch which is very showy. (EX)
- 'Marion Merriman'—Fringed chrome-yellow trusses, orange blotch. (KN)
- 'Mary Poppins'—Nasturtium red, dark green foliage. (KN)
- 'Matthew's Memory'—Golden yellow, 10 to 12' by 6 to 8'. (KN or EX?)
- 'Mavis'—Large dusty pink flowers in ball-shaped trusses. (KN)
- 'Mazurka'—Pale orange buds open to very large, ruffled flowers of apricot yellow, with pink tones intermingled. (KN)
- 'Mount St. Helens'—Yellow-pink with large red blotch, wavy petals, fragrant. (KN or EX?)
- 'Next to Hawaiian Lei'—Flowers are smaller in size, occur in large trusses with abundant flowers, pink buds turn a delicate light pastel pink on the lower petals contrasted by a very striking yellow gold flare on the upper petals. (EX)
- 'Old Gold'—Large, ball-shaped trusses of sunny orange gold, an even more orange flare on upper petal that merges into the solid gold of the lower petals. (EX)
- 'Orange Ball'—Solid orange, full ball-like trusses, medium green foliage. (EX)
- 'Orangeade'—Full and frilly, pure orange. (KN)
- 'Orient'—Hot orange-rose flowers with a yellow-orange flare, bronze green leaves in the fall turn a superb orange-red, vigorous, compact habit. (KN)
- 'Oxydol'—Large, white flowers with soft yellow blotch, bronze foliage. (KN)
- 'Peppermint'—Deep peppermint pink with lighter shades of pink and white on the midribs of the petals, creating a soft striped bi-color effect. (KN)

- 'Percil'—Flowers of white with a pale yellow blotch, fall foliage is outstanding brilliant reds and browns. (KN)
- 'Pink Delight' (PP 18,328)—Large flowers are deep rose-pink with a marking of soft orange on upper petals. (EX)
- 'Princess Royal'—Flowers are creamy white, flushed pink with a superb yellow blotch, sweet fragrance. (EX)
- 'Royal Lodge'—Late-flowering, vermillion red, wide-growing.
- 'Renne'—Flower of rich flame red suffused with yellow appears to be an almost solid, rich hot red, shiny foliage, fall color is dark maroon red. (EX)
- 'Salmon Pink'—Pink flowers, brilliant purple-red to yellow fall foliage, wide upright, vigorous. (EX)
- 'Satan'—Scarlet red. (KN)
- 'Scarlet Pimpernel'—Hot, red-orange flowers. (EX)
- 'Seville'—Orange-red flowers, notable for excellent fall color.
- 'Snowbird'—White, highly fragrant, compact. (KN or EX?)
- 'Strawberry Ice'—Peach-pink with yellow shadings; 10 to 12' by 6 to 8'. (EX)
- 'Sun Chariot'—Buttercup yellow, darker blotch.
- 'Sunset Pink'—Large trusses of vivid red with yellow blotch.
- 'Sunte Nectarine'—Brilliant orange flowers with a yellow blotch and a delightful fragrance.
- 'Sylphides'—Voluptuous pale pink and white with a touch of yellow in the throat, fragrant. (KN)
- 'Tangelo'—Soft, warm orange flowers, vigorous, easy to grow, withstands sun and heat. (EX)
- 'Toucan'—Pale cream with yellow blotch, very fragrant, tall growing. (KN)
- 'Tunis'—Deep crimson with orange flare, fast-growing, upright.
- 'Tutti Frutti'—Rose with large red blotch. (EX)
- 'Twinkle'—Yellow-orange, bi-color flowers, from the notable Arneson collection of Canby, OR. (KN)
- 'Twisted Leaf'—Orange buds and rich orange cream-colored flowers with a yellow flare, twisted leaves.
- 'Umpqua Queen'—Large, brilliant, sometimes double, sometimes single and sometimes semi-double, yellow trusses with vivid yellow blotches, profuse flowering, strong grower, hardy. (KN)
- 'Violet Gordon'—Bright orange beauty with bronze-tinted foliage. (KN)
- 'Wallowa Red'—Deep red flowers, mid-season, occasionally has 6 petals, open-round plant with arching branches reaching 4 to 8' in height with about a 3 to 5' spread. (KN)
- 'White Swan'—White with yellow blotch, very fragrant. (EX)
- 'White Throat'—Late-flowering, frilled, white flowers, red fall foliage, slow-growing, wide-spreading habit.
- 'Yachats'—Bright yellow flower sports a vivid orange flare, plants are taller and have larger leaves than most, named after the coastal Oregon Native American tribe. (EX)

Rhododendron fastigiatum Franch. — Autumnpurple Rhododendron
(rō-dō-den'dron fas-tij-ē-ā'tum)

Rhododendron fastigiatum is an excellent dwarf species for the rock garden with tiny, scaly, sea-green leaves and small lavender-purple flowers in April–May. Grows 2 to 3' high. 'Blue Steel' has striking, glaucous blue-green foliage and abundant deep lavender-blue flowers. Western China. Introduced 1911. Zone 6 to 7.

Rhododendron flammeum (Michx.) Sarg. (*R. speciosum* (Willd.) Sweet) — Oconee Azalea
(rō-dō-den'dron flam-ē-um)

Rhododendron flammeum grows 6 to 8' high and wide and forms a rather attractive mounded shrub. The scarlet or bright red, funnel-shaped, 1 3/4" long, non-fragrant flowers appear in April after *R. canescens*. Flowered late April in the Dirr garden. The truss may contain up to 15 flowers. The stamens are about 2" long. It has been confused with *R. calendulaceum* but differs in the slender corolla tube. The flower color ranges from yellow, pink, salmon to orange-red. Hybridizes in the wild with *R. canescens*. Georgia to South Carolina. Cultivated 1789. Zone 6 to 7.

Cultivars include:

- 'Apricot Speciosum'—Lovely soft shade of apricot with tangerine stamens, late April.
- 'Double Pleasure'—Double flowers, salmon; I see yellow and orange; flowered late April at Raulston.
- 'Glen's Pink'—Pink flowers.
- 'Harry's Speciosum'—Beautiful scarlet-red flower on a medium-sized, stoloniferous plant.
- 'Hazel Hamilton'—Bright yellow, heat tolerant, from Al O'Rear in Georgia.
- 'Orange Speciosum'—Huge, round, orange balls, full dense truss, hardy and a good grower.
- 'Peach Parfait'—Pink flowers in spring, 8'.
- 'Red Speciosum'—A beautiful, well-clothed, mounded plant, brilliant red flowers.
- 'Scarlet Ibis'—Brilliant dark orange-red flowers.
- 'Varnadoe'—Good orange selection by Mr. Aaron Varnadoe of Colquitt, GA.

Rhododendron* ×*furibishi (Lemmon & McKay) Hume
(rō-dō-den'dron fēr'bish-i)

Rhododendron ×*furibishi* is a very unusual native azalea, probably a hybrid between *R. bakeri* or a late *R. calendulaceum* type and *R. arborescens*, found in northern Georgia, mostly in orange and orange-red shades, a strong upright grower.

***Rhododendron* Gable Hybrids** are a mixed lot (azaleas and rhododendrons) but offer a quality range of colors and are considered among the hardiest evergreen azaleas for Zone 5 conditions. They were developed by the late Joseph Gable, a rhododendron hybridizer at Stewartstown, PA. These plants grow 2 to 4' high and as wide. The foliage is a shiny dark green, about 1" long, although there is considerable variation among clones. The flowers arrive in late April to early May and are about 2" across. The following cultivars were synthesized from the literature and observations. Hybridizer is listed when known. Parents include *R. yedoense* var. *poukhanense* and *R. kaempferi*. Listed as Zone 6 to 9.

'Ben Morrison'—(Gable) Red and white striped.

'Big Joe'—Reddish violet.

'Blaauw's Pink'—Shrimp pink, hose-in-hose, mid-season; 3/4" leaves; semi-upright with an abundance of flowers.

'Boudoir'—(Gable) Watermelon pink, darker blotch, compact plant, 5' by 4', did well in my Illinois garden.

'Cadis'—Deep pink buds are a lovely contrast to large fragrant light pink flowers in flat trusses, large growing (rhododendron).

'Cameo'—Hose-in-hose pink.

'Carol'—Hose-in-hose violet-red flowers, low-spreading habit.

'Caroline'—(Gable) Large heavy textured pale orchid flowers, large leaves with wavy margins, does well in hot climates but appreciates partial shade, medium height (rhododendron).

'Cherokee'—Orange-red flowers, upright growing, medium height.

'Conemaugh'—Lavender pink trusses of lovely star-shaped flowers, late April into early May, 4' (rhododendron).

'Corsage'—Fragrant, light lavender, 2 1/2" diameter, rounded dwarf plant, 4' by 4'.

'County of York'—Large, white flowers with pale green throat, pale lavender-pink buds, wide-growing, lustrous, long, convex, apple-green leaves.

'David Gable'—(Gable) Red-throated pink flowers in large, dome-shaped trusses, floriferous, medium height (rhododendron).

'Early Bird'—Vigorous plant, lavender-pink flowers in clusters early in the season, bright green, heavily textured leaves, upright plant.

'Elizabeth Gable'—Frilled, salmon pink flowers in June, upright-spreading, very hardy and evergreen.

'Forest Fire'—Hose-in-hose red.

'Gable's Pink Conewago'—(Gable) A tighter growing form of 'Conewago' with pinker flowers in early May, 4' (rhododendron).

'Gable's T-4-G'—(Gable) Double, salmon pink flowers, very dwarf and slow growing, late May.

'Herbert'—Possibly the hardiest of all Gable hybrids, vivid purple with darker blotch, hose-in-hose, 1 3/4" long, dense rounded habit, 4' by 4', flower bud hardy to -20°F, has performed well in Zone 7, was the hardiest azalea in our Illinois garden.

'Jessie Coover'—Deep pink, double, hose-in-hose flowers, late May to early June.

'Karen'—Lavender pink, hose-in-hose, rounded habit, 4' by 4', excellent cold hardiness, similar to 'Herbert'.

'Katherine Dalton'—Light pink buds open to fragrant, blush pink flowers in mid-May, very hardy, tall.

'Keisrac Pink'—(Gable) Small leaves and flowers suggesting the pointed pink and white flower of *Arbutus*, compact.

'La Roche'—Single, magenta red flowers, early May, extremely bud hardy, 4 to 5'.

'Lorna'—(Gable) Masses of double, pink flowers resembling rosebuds, compact low-spreading habit.

'Louise Gable'—Double, deep salmon-pink, darker blotch, 2 1/2" across, rounded dense habit, 3 to 4' by 3 to 4'.

'Madame Greeley'—Single, large, white with green flecks in throat, 1" wide, rounded compact habit, 3' by 3'.

'Mary Dalton'—Orange-red.

'Maxecat'—Pink flowers, late flowering, hardy, vigorous form, 6'.

'Mildred Mae'—(Gable) Large, spotted lavender.

'Old Faithful'—Large, orchid pink flowers with a darker blotch, early May, very bud hardy, 6'.

'Olive'—Orchid-purple flowers, hardy, compact and spreading.

'Pink Rosette'—Bright rose red, double flowers, late May well into June, low growing.

'Purple Splendor'—(Gable) Purple, hose-in-hose.

'Robert Allison'—(Gable) Scented, pink flowers with golden throats, large waxy green leaves on a rugged upright shrub, medium height.

- 'Rose Greeley'—Large hose-in-hose white flowers with chartreuse blotch, dense low-spreading plant, 3' by 3'.
- 'Rosebud'—(Gable) Silvery rose-pink, double, hose-in-hose, 1 to 2" diameter, compact habit, 4' by 4', flowers resemble miniature roses, very popular cultivar.
- 'Springtime'—(Gable) Clear pink, early flowering.
- 'Stewartstown'—(Gable) Vivid, brick-red, small single flowers, foliage dark green and wine-red in winter; rounded habit, 5' by 4'; flowers later, although listed as very cold hardy it is distinctly less so than 'Herbert' and 'Karen'; grew this in our Illinois garden and it was ruined above snow line; in Manchester, NH I was told this is an adaptable cultivar, possibly due to winter snow cover because low temperatures hover in the -25 to -30°F range.
- 'Tryon Pink'—Medium pink, hose-in-hose flowers, mid-season, good compact habit, vigorous, with good foliage.
- 'White Rosebud'—A beautiful pure white, double flowers, resembles buds of a rose, 1 1/2 to 2" wide when open.

***Rhododendron* ×*gandavense* Rehd. — Ghent Azaleas**
(rō-dō-den'dron gan-da-ven'sē)

Rhododendron ×*gandavense* are deciduous, 6 to 10' shrubby growers with flower colors ranging from pure white, pure yellow, to combinations of pink, orange and scarlet. Flowers are single or double, the doubles with numerous overlapping petals, 1 1/2 to 2" across, usually fragrant, with long-tubed, honeysuckle flowers opening in May–June. The hybrids were developed by crossing several species and some of the select clones are hardy to -20°F.

Cultivars include:

- 'Bouquet de Flore'—Orange-red flowers with yellow center, somewhat frilled, upright.
- 'Circus'—Yellow maturing to pink.
- 'Coccinea Speciosa'—Orange.
- 'Daviesi'—White to pale yellow, 2 1/4" diameter flowers, tall growing, reasonable heat tolerance, fragrant.
- 'Fanny'—Violet-red, yellow center.
- 'Gloria Mundi'—Orange-yellow-red combination.
- 'Magic'—Yellow, maturing to orange.
- 'Nancy Waterer'—Large golden yellow.
- 'Narcissiflora'—Double, yellow, hose-in-hose, fragrant, fine form, reasonable heat tolerance.
- 'Pallas'—Orange-red.
- 'Rainbow'—Yellow, maturing to orange-yellow.

Developed in Ghent, Belgium around 1820–1830 from *R. arborescens*, *R. atlanticum*, *R. calendulaceum*, *R. canescens*, *R. molle*, *R. luteum*, *R. periclymenoides*, *R. viscosum*, and *R. flammeum*. In general the Ghent hybrids are best suited to cooler climates. 'Narcissiflora', as mentioned, is a fine form. Hillier (2002) noted breeding in early 19th century in Ghent; 1830–1850 in England, more recently in United States.

***Rhododendron* *hyperythrum* Hayata**
(rō-dō-den'dron hī-per-rē'thrum)

Rhododendron hyperythrum was unknown to the author until moving to the Chapel Hill area. Sarah P. Duke Gardens and the Raulston Arboretum have superb 3 to 5' high, slightly wider, specimens, essentially dark green mounds; leaves leathery, rigid, recurved, lustrous dark green, the underside dotted with reddish markings. Flowers in large trusses, early April, Duke Gardens, buds rich pink, opening pink to white, quite spectacular. Reminds somewhat of *R. yakushmanum*, particularly in the flowers. Displays high heat tolerance and for that reason it might prove a worthy garden plant for Zone 7 and 8 as well as a breeding parent. With absoluteness, I can state that during my 30 years in Georgia, I observed more large leaf rhododendrons that died or languished than grew into respectable garden plants. Has been utilized in breeding to produce heat tolerant, large-leaf rhododendrons. Taiwan.

***Rhododendron* *impeditum* Balf. F. & W.W. Sm. — Cloudland Rhododendron**
(rō-dō-den'dron im-ped-i'tum)

Rhododendron impeditum forms a cushion of small dark green evergreen leaves upon which purple or bluish purple flowers are produced in April–May. It is an attractive, small rhododendron with good hardiness and for that reason should be considered in the colder regions of the country. 'Moerheim' is a *R. impeditum* hybrid from Holland with small violet flowers and tiny leaves on a tight, compact dwarf. 'Passionate Purple' has deep purple flowers and small leaves, summer foliage is olive green, winter foliage is reddish purple, 2'. Western China. Introduced 1911. Zone 5 to 6.

***Rhododendron kaempferi* Planch.**

(rō-dō-den'dron kem'fēr-ī)

Rhododendron kaempferi hybrids can grow to 10' high and 5 to 6' wide after 5 to 10 years. The 1 1/2 to 3" long, strigose pubescent leaves are dark green, semi-evergreen to deciduous and turn reddish hues in fall and winter. The flowers range in color from salmon-red, orange-red, pink to rosy scarlet and white; each flower 1 3/4 to 2 1/2" long and wide, funnel-shaped, 1 to 4 per truss. Flowers open in May–June. This is a very variable species and apparently has interbred with *R. obtusum* producing large hybrid swarms which dot the mountainsides of Japan. A parent of the Kurume azaleas. Usually found in sunny positions on hillsides, by the sea, on active volcanoes and also in thickets, pinewoods and deciduous forests. The species is found wild on the main islands of Japan from sea-level to the lower hills below 2,600'. Introduced 1892. Zone 5 to 7.

Several cultivars of merit include:

- 'Alice'—Salmon-red.
- 'Annamarie'—Pure white, small flowers, bright yellow autumn foliage, wide-spreading, upright outline, 6' high, -13°F bud hardiness.
- 'Campfire'—Red, hose-in-hose.
- 'Carmen' (PP 16,839)—Red.
- 'Charlotte'—Dark orange-red.
- 'Christina'—Red, 2" diameter, single, medium-sized shrub.
- 'Dorsett'—Bright salmon red flowers, upright selected form of *R. kaempferi*.
- 'Fedora'—Phlox-pink, with darker blotch, 2" diameter, rounded habit, 6' by 5 to 6', reasonably common in commerce.
- 'Gretchen'—Reddish violet.
- 'Holland'—Single, large rich intense red, synonymous with 'Holland Red'.
- 'Johanna'—Red, 2" diameter single flowers, medium-sized shrub.
- 'Juliana'—Deep pink.
- 'Kathleen'—Rosy red.
- 'Mary'—Violet-red.
- 'Mikado'—Dark red flowers, burgundy-red fall foliage, upright growth habit, synonymous with 'May King'.
- 'Norma'—Violet-red.
- 'Othello'—Red.
- 'Pride of Planting Fields'—Bright orange-red, double flowers, upright-mounded habit, semi-evergreen with bright green summer foliage, from Planting Fields Arboretum.
- 'Tachisene'—Small, very double, bright salmon-pink flowers in June, slow-growing, low-spreading, dwarf form.
- 'White Squall'—Pure white flowers with an accenting green flare which is the same color as the newly emerging leaves, foliage later darkens and is of larger size, compact and low branching.

***Rhododendron keiskei* Miq. — Keisk Rhododendron**

(rō-dō-den'dron kīsk'ē-ī)

Rhododendron keiskei grows 4 to 5' (1 to 10' in some references) high and is of scraggly habit. Evergreen to semi-evergreen in foliage, leaves 1 to 3" long, lanceolate. Lemon-yellow flowers, early to mid-May, 3 to 5 flowers per cluster. It is one of the few evergreen rhododendrons with pale yellow flowers. Have observed it in flower in Urbana, IL, but it was less than inspirational. Much used in hybridizing. In fact, my survey of catalogs and literature uncovered interminable named hybrids. Japan. Introduced 1908. Zone 5.

***Rhododendron kiusianum* Mak. — Kyushu Azalea**

(rō-dō-den'dron kī-ō'sē-ā-num)

Rhododendron kiusianum is a dwarf evergreen or semi-evergreen shrub, occasionally up to 3', dense spreading habit. Leaves are dark green, small and oval shaped. Flowers are funnel-shaped, produced in clusters of 2 to 5. Colors range from white, red to purple, hardy to 0°F, flowers late May–June. Kyushu, Japan. Zone 6 to 8. Introduced 1812 by E.H. Wilson.

Cultivars include:

- 'Album'—Delicate white flower.
- 'Benichidori'—Small, bright reddish orange flowers.
- 'Benisuzume'—A reddish orange flower on a low-spreading plant.
- 'Betty Muir'—Vibrant pink, foliage is very dark green and covered with tiny hairs.
- 'Brick Red'—Tiny, dark orange-red flowers, dwarf.
- 'Chidori'—White flowers.
- 'Hanejiro'—White flowers.

- 'Hanekomachi'—Bright, pinkish red, Japanese selection.
 'Harunokikari'—Lavender-blue flowers.
 'Harunoumi'—Soft pink flowers early in the season.
 'Harusame'—Bright pink flowers.
 'Hilliers Pink'—Clear lilac-pink flowers.
 'Hinode'—Clearest red.
 'Komo Kulshan' (also 'Komokulshan')—Small flower with a pale pink center and a rose margin.
 'Mai Oghi'—Bright rose pink flowers.
 'Mangetsu'—Delightful two-toned appearance with lavender-pink on the tips and light pink in the center.
 'Murasaki Shikibu'—Reddish purple, hose-in-hose flowers.
 'Myamo Katsura'—Vivid bright reddish purple flowers.
 'Nu Moto'—Lovely purple form.
 'Rose'—Rose flowers, small leaves and habit of the other Kiusianums but a slightly larger grower.
 'Short Circuit'—Especially bright pink color.
 'Ukon'—This Japanese diminutive has delicate pink flowers.
 White Form—Rare albino form, flowers young and heavily.
 'Yumbae'—Pinkish flowers.

Rhododendron ×kosteranum Schneid. — Mollis Hybrid Azaleas
 (rō-dō-den'dron kos-tēr-ā'num)

LEAVES: Alternate, simple, entire, 1 1/2 to 4" long, obovate to oblong-ovate, apex bluntish, with a gland-like tip, base wedge-shaped, margin hairy on upper surface or becoming hairless, bristly-hairy on veins beneath.
 BUDS: Flower—1/4 to 1/2", imbricate, tip of scales tinged brown.

Rhododendron ×kosteranum are somewhat similar to the Exbury group in flower characteristics but usually smaller (4 to 6' high) and not as hardy, although from observations in the Midwest, I believe the hardiness is excellent. Foliage is deciduous. Generally yellow to orange flower color. Resulted from crosses between *R. molle* subsp. *japonicum* × *R. molle*. Originated in Holland and Belgium in the 1870's.

Cultivars worth considering include:

- 'Chevalier de Reali'—Maize yellow, fading to cream, fragrant.
 'Christopher Wren'—Yellow.
 'Consul Ceresole'—Rose-pink.
 'Dr. M. Oosthoek'—Darkest fire red-orange of the mollis group, hot orange color.
 'Golden Sunrise'—Handsome yellow flowers in large trusses.
 'Koster's Brilliant Red'—Flowers of brilliant orange-red.
 'Lemon Twist'—A pleasing light yellow with uniquely twisted stems and branches, spreading growth.
 'Queen Emma'—Large, light salmon-orange flowers, 10' high, vigorous, synonymous with 'Koningin Emma'.
 'Snowdrift'—White.
 'Yellow Mollis'—Yellow flower, prolific.

Rhododendron ×laetevirens Rehd. — Wilson Rhododendron
 (rō-dō-den'dron lē-ti-vī'renz)

Rhododendron ×laetevirens is a small (2 to 4' by 2 to 6'), low growing, glossy leaved, evergreen shrub with pink to purplish flowers. Makes a good, neat, small evergreen plant in the rock garden or for foundation planting. Actually one of the finest evergreen foliaged rhododendrons, unfortunately the flowers are third rate. Zone 4 to 6. Result of a cross between *R. minus* Carolinianum Group × *R. ferrugineum* L.

Rhododendron luteum Sweet — Pontic Azalea
 (rō-dō-den'dron lū'tē-um)

Rhododendron luteum is a handsome 8 to 10'(12') high shrub that produces fragrant, rich yellow, 1 1/2 to 2" diameter flowers on naked stems in May. It is truly beautiful in flower and I will always remember a particular striking specimen in the border along Meadow Road at the Arnold Arboretum. It is a vigorous species and has been used in hybridizing. Common in European gardens where it appears to thrive with neglect. 'Batumi Gold' has large, bright yellow flowers in a ball-shaped truss with long stamens; reliable heavy flowering. Asia Minor, Caucasus, eastern Europe. Introduced 1793. Zone 5 to 6.

***Rhododendron maximum* L. — Rosebay Rhododendron**

(rō-dō-den'dron maks'i-mum)

Rhododendron maximum grows 4 to 15' in the North but can grow to 30'; habit is loose and open. Tri-national champions are 28' by 36' in Rabun, GA, 28' by 28' at the Biltmore Estate, Asheville, NC, and 34' by 28' at Sumter National Forest, SC. Leaves are large (4 to 8" (12") long) and evergreen (dark green). Flowers are rose, purplish pink to white, spotted with olive-green to orange, 1 to 2" across, June. Requires moist, acid soil and shade protection. Occurs in abundance throughout the southern Appalachian mountains along streams. Requires cool, moist, well-drained root run and is not ideally suited to "normal" landscape situations. Have observed many times in north Georgia where it often forms pure thickets. Flowers most often pink in bud, opening white, usually June–July in north Georgia. Early July in Highlands, NC area. The trunks are brown, lightly ridged-and-furrowed, somewhat twisted and quite beautiful in syncopated composition. Native from Nova Scotia and Ontario to Georgia, Alabama and Ohio. Introduced 1736. Zone 3 to 7.

Cultivars include:

var. *album* Pursh—White flowers.

'Leachii'—Recurved, curly and wider deep green leaves, slower growing and more compact, pinkish white flowers.

'Midsummer'—Rouge pink flowers with a glint of gold in the throat in compact trusses, deep forest green leaves, somewhat open habit.

'Pride's Pink'—Good-sized pink flowers, extremely hardy, upright-spreading.

var. *purpureum* Pursh—Deep pink to purple flowers.

'Roseum' (var. *roseum*)—Flowers are reddish in bud, turning to pink, red stems and dark green leaves, vigorous, 8 to 12'.

***Rhododendron molle* (Bl.) G. Don subsp. *japonicum* (A. Gray) Kron (previously *Rhododendron japonicum* (A. Gray) Sur.) — Japanese Azalea**

(rō-dō-den'dron mōl'lē ja-pon'i-kum)

Rhododendron molle subsp. *japonicum* is a bushy shrub of rounded outline that grows 4 to 8' high. The fragrant flowers are beautiful and range from yellow, orange-yellow, soft rose, salmon-red, orange-red to brick-red in color. Each flower is 2 1/2 to 3 1/2" wide, and produced in trusses of 6 to 10 during May at the end of leafless stems. It is one of the parents of the Ghent hybrids and also figures in the Mollis hybrids (*R. ×kosteranum*). The subspecies has proven a fairly reliable flowerer at Minnesota (best in Zone 5). Japan, where it is found in open grassland, never in woods or dense thickets. Introduced 1861.

Rhododendron molle, Chinese Azalea, is similar but differs in the conspicuous pubescence on the underside of the leaf and buds. It grows 2 to 5' high and although hardy (Zone 5) is not as vigorous as subsp. *japonicum*. Flowers are yellow.

***Rhododendron nakaharae* Hayata**

(rō-dō-den'dron nak-a-har'i)

Rhododendron nakaharae is a dwarf, compact, spreading, evergreen azalea with densely appressed, pubescent shoots. Great potential as a ground cover. Orange-red to red, funnel-shaped, 3/4 to 1" long flowers in June–July. Northern Taiwan. Introduced 1960. Zone 6 to 9.

Cultivars include:

Dwarf Form—Tiny buds that open red, smaller (1' high) than the species, 1/2" long, green, hairy leaves.

'Mount Seven Star'—Low spreading habit, 4" high; flowers bright red with wavy-edged lobes and minute purple spots.

'Nakahari Mariko'—Red to red-orange flowers, 2 to 3 in a cluster, late-flowering, dwarf, minute, glossy green foliage.

'Nakahari Mini-pink'—Large, clear pink flowers, slow-growing dwarf.

'Nakahari Salmon Pink'—Salmon pink flowers, very prostrate ground cover with hairy leaves.

***Rhododendron* 'Northern Lights'** resulted from crosses between *R. ×kosteranum* and *R. prinophyllum*. The original crosses were made in 1957 by the late Albert G. Johnson. Plants became commercially available in 1978. Originally they were produced from seed with resultant variations in flower color. Flowers range from white, light to deep pink, lilac, yellow, orange and have the pleasing fragrance of *R. prinophyllum*. Each flower is about 1 1/2" long and occurs in trusses of up to 12. The plants are compact and grow 8 to 10' high and wide. The flower buds occur on naked stems in May and are spectacular. I had one of the "culls" in my Illinois garden and it was fantastic. I realize fantastic is a relative term but when one lives in central Illinois and has an insatiable desire to grow flower bud hardy azaleas he/she has very few choices. 'Northern Lights' azaleas are flower bud hardy to -40°F. See *J. Environ. Hort.* 15(1):45-50 (1997) for 'Mandarin Lights',

'Spicy Lights', and 'White Lights' cold hardiness ratings. All were hardy to -30°F and below. Plants are now quite common in commerce with the success of tissue culture propagation. Flowers with the leaves in mid to late April, Raulston Arboretum. Original introductions were quite mildew susceptible.

Cultivars include:

- 'Apricot Surprise'—Bright yellow-apricot with orange shadings.
 - 'Candy Lights'—Lavender-pink, early flowering; improved mildew resistance, medium green foliage; 3 to 4' by 3 to 4'.
 - 'Golden Lights'—Golden yellow, fragrant; listed as 4 to 5' by 3 to 4'.
 - 'Lemon Lights'—Lemon yellow flowers; 4 to 5' by 3 to 4'.
 - 'Lilac Lights'—Deep, non-fading, lilac flowers; uniform, semidwarf habit; medium green leaves turn light yellow in fall; 3 to 4' by 3 to 4'; considered an improved form of 'Orchid Lights'.
 - 'Mandarin Lights'—Bright orange, ruffled; 4 to 5' by 4 to 5'.
 - 'Northern Hi-Lights'—Bi-colored, creamy white, yellow upper petal, mildew resistant foliage, red fall color; 4' by 5'.
 - 'Northern Lights'—Pink flowers; 4 to 5' by 5 to 6'.
 - 'Orchid Lights'—Semi-dwarf, bushy, lilac flowers; sterile; 3' by 3 to 4'.
 - 'Pink Lights'—Light pink flowers, sweet scent; 8' by 8'.
 - 'Rosy Lights'—Fragrant dark pink, rose-red shading; 4 to 5' by 5 to 6'.
 - 'Spicy Lights'—Soft tangerine-orange, fragrant; 6' by 8'.
 - 'Tri-Lights'—White with pink tinge, yellow blotch; good resistance to powdery mildew; 4' by 5 to 6'.
 - 'Western Lights'—Larger lilac-pink flowers, thicker, more lush foliage with glaucous cast, tetraploid; Briggs Nursery introduction.
 - 'White Lights'—Large, fragrant, pale pink opening white with yellow blotch; 6' by 6'.
- Bred at University of Minnesota Landscape Arboretum. Dr. Harold Pellett, now retired, continued Mr. Johnson's work.

Rhododendron oblongifolium (Small) Millais — Texas Azalea
(rō-dō-den'dron ob-long-i-fō'li-um)

Rhododendron oblongifolium grows 6' high and has distinct obovate to oblanceolate, 1 1/2 to 4" long leaves. The slightly fragrant, funnel-shaped, pure white, 3/4 to 1" long flowers occur in 7- to 12-flowered trusses after the leaves. Related to *R. viscosum* and *R. serrulatum* and some taxonomists would argue that it is not a distinct species. The species should be lumped with the above mentioned for the differences are within the purview of those species. Grew a plant in Georgia garden with light pink flowers and a soft lemon-spice fragrance in late May–June. The plant was never comfortable living in Athens. Moral, grow *R. canescens* and *R. austrinum*. Flowered in mid-June at Sarah P. Duke Gardens. Flowers fragrant with corolla tube sticky. Found in moist sandy woods or on the margins of sandy bogs and streams and even on limestone in Arkansas, Oklahoma and Texas. Introduced 1917. Zone 7(?)

Rhododendron obtusum (Lindl.) Planch. or **Obtusum Group** — Hiryu or Kirishima Azalea
(rō-dō-den'dron ob-tūs'um)

Rhododendron obtusum is a spreading, dense evergreen to semi-evergreen shrub with glossy green leaves up to 1 1/4" long. The flowers are reddish violet, but bright red, scarlet and crimson forms occur. Each flower may be 3/4 to 1" across, funnel-shaped, 1 to 3 per truss. Nomenclature is somewhat confusing and is often referred to as Obtusum Group. Found wild in highly acid soil on three mountains in Kyushu, Japan. Introduced about 1844. Zone 6. There are a number of cultivars which have been derived from *R. obtusum*, *R. kaempferi*, *R. kiusianum*, and *R. satense*. This group has the name Kurume Azaleas (see Kurume Hybrid list) and while often considered dwarf they will develop into dense, 4 to 6' high plants. Many of the cultivars have been used for greenhouse forcing and are simply not hardy in the northern areas. The range of colors travels from white to pink, lavender, scarlet, salmon and all shades in between. As hybridization continues new and better cultivars will appear in the trade. The real crux is being able to separate the good flowering, hardy (at least to -10°F) types from the rest of the lot. Callaway Gardens has an excellent collection of Kurumes and their famous Azalea bowl is primarily planted with this group. 'Amoenum' has small, hose-in-hose, purplish red flowers, small shiny leaves, early to mid-May.

Rhododendron periclymenoides (Michx.) Shinn. (previously *R. nudiflorum* Torr.) — Pinxterbloom Azalea
(rō-dō-den'dron per-i-clī-men-oy'dēz)

Rhododendron periclymenoides is a low, much-branched, stoloniferous, deciduous shrub which averages 4 to 6' in height but ranges from dwarfish (2') to relatively large (10') over the native habitat. The foliage is bright green in summer turning dull yellow in fall. The flowers vary in color from impure white or pale pink to deep violet and open in April or early May. Based on numerous visits to the azalea garden at Biltmore

Estate, the flowers open with, or perhaps slightly later than *R. austrinum* and *R. canescens*. The flowers are fragrant (variable), each about 1 1/2" across, corolla sticky, borne 6 to 12 together before the leaves. This species is adapted to dry, sandy, rocky soils. Observed in flower in April at 4,000' elevation in north Georgia mountains. Full flower May 13, 2006, Blue Ridge Parkway near Fancy Gap, VA. A useful plant for naturalizing, and along with *R. calendulaceum* and *R. viscosum* was used in the development of the Ghent hybrids. Native from Massachusetts to North Carolina, Georgia and Ohio. Introduced 1734. Zone 4 to 8.

***Rhododendron* 'P.J.M.'**

LEAVES: Small, 1 to 2 1/2" long, usually elliptic, dark green above, changing to purple in winter, essentially hairless, rusty-scaly beneath, thick, leathery.

BUDS: Rounded and much smaller than those of *R. catawbiense*.

Rhododendron 'P.J.M.' hybrids resulted from crosses between *R. minus* and *R. dauricum* var. *sempervirens*. The 'P.J.M.' Hybrids are a group of plants and, therefore, there may be differences in flower colors. The plant grows from 3 to 6' in height and is of rounded outline. The foliage is evergreen, dark green in summer and turns plum purple in fall. The flowers are vivid, bright lavender pink and occur in mid to late April. The flowers occur heavily every year as the plant sets little or no seed. Zone 4 hardiness. Dr. Donald Wyman said the 'P.J.M.' Hybrids were the most promising rhododendrons that have originated in New England. Originated in the Weston Nurseries, Hopkinton, MA, 1943. Many people do not like the "dirty, squalid lavender-pink flowers" but when the choice of rhododendrons is limited this is a bright element in the landscape. 'P.J.M.' grew in our Illinois garden and proved the hardiest broadleaf rhododendron. Minnesota Landscape Arboretum reported that it was the only flower bud hardy broadleaf rhododendron. Report from Calgary, Alberta, Canada that 'P.J.M.' flowers there, see *Amer. Nurseryman* 180(6):106 (1994). It flowered in our garden along with daffodils and was a pleasant sight especially after a difficult midwestern winter.

MEZITT/WESTON HYBRIDS: The following is an attempt to assemble the fruits of the Mezitt's long tradition of breeding. Wayne Mezitt is continuing to breed garden-worthy rhododendrons and azaleas.

'Abbey's Review'—A fall and spring flowering selection discovered in Georgia and marketed by Abbey Nursery and Transplant Nursery; same habit, foliage, adaptability as 'P.J.M.' but appears to do better in the South.

'Aglo'—Sister of 'Olga Mezitt', selected for its earlier flower and dark blotch, compact grower with light pink flowers.

'Amy Cotta'—Compact, dense, slow-growing, forming a rounded cushion to 3' high; small, ruffled, lavender-pink flowers; sport of 'PJM' selected in 1982.

'April Love'—Ruffled, double, light pink and yellow, some winter foliage retention, less than 50%, 6' by 4'.

'April Snow'—Attractive small foliage becomes bronzy in winter, white flowers in mid-April, dense twiggy upright habit, stems yellow-green; 4'.

'April Song'—Large, frilly, double, light pink flowers at the end of April, inner set of petals are nearly white, imparting an unusual two-tone appearance, small, dark green leaves turn yellow and mahogany-red in autumn and are retained about fifty percent during winter, chunky, wide-growing upright shrub, 5' by 4'.

'Balta' (*R. minus* var. *album* × 'P.J.M.' Hybrid)—Small, glossy, partly convex evergreen leaves, compact and slow in growth, flowers a week after 'P.J.M.' hybrids, pale pink to almost white; to 4'.

'Big Deal'—Rounded habit; ivory-yellow flowers; flower bud hardy to -13°F; to 6'.

'Black Satin'—An F3 hybrid of 'P.J.M.' hybrids, deep fall and winter foliage color, which is shiny coal-black, semi-upright in growth habit, flowers are a deep rose-pink; in full, attractive flower May 28, 2005, Orono, ME.

'Blue Baron'—Compact mounded outline; near blue flowers; shiny green summer leaves, bronze in winter; to 4'.

'Bonfire'—Small, orange-red.

'Checkmate'—Small, lavender-pink flowers, compact, mound-like bush, most "dwarf" form of *R. 'P.J.M.'*; dark mahogany winter foliage; to 4'.

'Commonwealth'—Vigorous, upright; dark red flowers in late May; large, leathery dark green leaves; to 8'.

'Counterpoint'—Sister of 'Marathon', deciduous upright-spreading plant with semi-double, bright pink flowers along the entire length of the stems.

'Desmit'—A sister seedling of 'Waltham', selected for one week earlier flowering time and appears less susceptible to the sunscalding leaf spot problem.

'Elite'—A most vigorous selection of 'P.J.M.', tall growing, flowers are slightly pinker and open a few days later than 'Victor'.

- 'Frank Abbott'—Deciduous, vibrant, dark pink, spicy-scented flowers in late May, wide-growing, robust, upright, clusters of silvery, pointed buds, large, mildew-resistant foliage often turns reddish orange before dropping in autumn, hybrid between the rock-hardy *R. prinophyllum* and a red flowering *R. xkosteranum* selection, Ed Mezitt performed this cross in the 1960's.
- 'Glacier Queen'—Slow-growing; pure white flowers with yellow eyes; large, flat, dark green leaves; to 5'.
- 'Golden Scepter'—Large trusses of light yellow flowers in May; glossy dark green leaves; more loose and open when young; 6'.
- 'Golden Showers'—Lightly vanilla-scented, peach-yellow flowers, broad, upright growing, long, pointed, somewhat glossy green leaves, bronze in fall, -24°F.
- 'Henry's Red'—Very dark red, deeper red throat; wide and upright with dark green, slightly twisted foliage; one of the hardiest reds, have seen in Manchester, NH; about a 4th generation seedling; 6'.
- 'Hudson Bay'—White; 4'.
- 'Independence'—Upright growing, small green leaves with bluish undersides, red buds, small fragrant dark pink flowers in ball-like heads, maturing silvery-pink in July.
- 'Iridescent'—Spicy-scented, silvery pink in mid-June, wide-spreading, green foliage with a blue cast turns bronze-red in fall, -29°F.
- 'Jane Abbott Peach'—Large peach-pink fragrant flowers, vigorous, wide, upright-growing, -29°F.
- 'Jane Abbott Pink'—Cutting grown selections of *R. xkosteranum* × *R. prinophyllum* hybrid, large, fragrant flowers in shades of pink, wide, upright, robust, -29°F.
- 'June Pink'—Compact, maturing wide as high; clear pink flowers; bright green leaves; one of the latest flowering, small-leaf rhododendrons; 4'; 'Olga Mezitt' 2nd generation seedling.
- 'Landmark'—Dark pink flowers in early May; leathery dark green leaves turn bronze-mahogany in winter; 5'.
- 'Laurie' (*R. minus* var. *album* × 'P.J.M.' hybrid)—Glossy green leaves turn red in fall and winter, compact and slow in growth, flowers pale pink to almost white with some branches exhibiting semi-double petaloid flowers just after 'P.J.M.'; 4'.
- 'Lavender Frost'—Profuse, ruffled, multi-petaled, light lavender to white flowers, small, dark green leaves turn bronze or mahogany in fall, 5' by 4'.
- 'Legacy'—Robust, upright grower; full double, deep purple flowers in late April; foliage similar to 'PJM'; 8'.
- 'Lemon Drop'—Peach colored buds open pale yellow with spicy fragrant flowers in late June–July; glossy green leaves turn dark wine-red in fall.
- 'Little Olga'—Clear pink flowers; small glossy leaves; grows 2/3 the size of 'Olga Mezitt', 4'.
- 'Llenroc'—Dusty pale pink to almost white; to 4'; Shrimp Pink hybrid.
- 'Lollipop'—Pink flowers with yellow flare, maturing silvery pink, with a sweet fragrance; mildew-resistant, green leaves have silvery undersides and change to long-lasting red-orange in September.
- 'Low Red Frilled'—Medium red flowers with frilled edges, low-spreading and compact, dark green foliage.
- 'Lynne Robbins Steinman'—Clone of the Double Pink Hybrids, opening as early as the third week of April in Hopkinton, MA, ruffled, double flowers with yellowish centers, small foliage, nearly deciduous in winter.
- 'Marathon' (An F2 hybrid of 'P.J.M.' × *R. mucronulatum* 'Cornell Pink')—Deciduous, semi-upright habit, bright magenta flowers early, usually the day (April 19) of the Boston Marathon, which starts in sight of Weston Nursery, Hopkinton, MA.
- 'Mary Kittel'—Small dark pink flowers; bright green convex leaves; compact mounding habit, 4'.
- 'Midnight Ruby'—Red-purple flowers; green summer foliage turns black-bronze in winter; 5'.
- 'Milestone'—Pink buds in mid to late April open to darker pink flowers, appear nearly red from a distance, small, green, slightly twisted and shiny foliage, few leaves that are retained on the branch tips in winter are mahogany colored, orange-red and yellow interior leaves in November, compact-growing shrub with a wide, upright, twiggy appearance, 3' high and wide after 10 years, larger with age, 5'.
- 'Millennium'—Deep red, fragrant flowers with a pale orange flare, late flowering, June–July; blue-green, mildew-resistant foliage, deciduous; listed 3' by 2 1/2'.
- 'Mindaure' (*R. minus* var. *compacta* × *R. dauricum* var. *sempervirens*)—Evergreen foliage, green in summer, deep purple in fall and winter, foliage is thinner in texture than 'P.J.M.', wide-spreading habit of growth, flowers a week after *R. 'P.J.M.'*, discontinued and now used only for hybridizing.
- 'Minna's Purple'—Dark purple flowers in mid May; large, convex, dark green foliage, resistant to wind burn; to 6'; *R. catawbiense* seedling.
- 'Molly Fordham'—Compact growing, white flowers, small glossy green foliage year-round, early May, named after Molly Fordham, wife of the late Alfred Fordham, the great propagator at the Arnold Arboretum.
- 'Mrs. J.A. Withington III'—Fully double, light to medium lavender flowers; dark green foliage turns mahogany in winter; 5'.
- 'Nantucket'—Bright pink flowers; long, curved, dark green foliage; 6'; *R. catawbiense* seedling.
- 'New Century'—Coppery-yellow buds open to ivory flowers; glossy green leaves; compact and slow-growing; 4'.

- 'New Patriot'—Violet-red flowers in mid-April, purplish-maroon winter foliage, 3 to 4', upright-spreading habit, some winter foliage retention.
- 'Nor'easter'—Pale lavender buds open white; rounded, dark green leaves; compact habit for a *R. catawbiense*; 5'.
- 'Northern Rose' (*R.* 'Waltham' $\times$ *R. mucronulatum* 'Cornell Pink', crossed by Dr. Robert Ticknor)—Narrow evergreen foliage on a semi-upright plant, small bright pink flowers in abundance at or slightly after 'P.J.M.', difficult to propagate but may become popular through tissue culture.
- 'Northern Starburst' (PP 10,388)—Intense mauve flowers, lustrous dark green summer leaves, purple-black winter foliage, tetraploid; 4 to 5' by 3 to 5'; colchicine-induced selection by Briggs Nursery.
- 'Olga Mezitt' (*R. minus* var. *compacta* $\times$ *R. mucronulatum*)—Evergreen foliage turning light red in fall and winter, vigorous upright-spreading plant, bright peach-pink flowers about the time of *R. minus*; full flower April 29, 2005 at Swarthmore College; one month later in Orono, ME.
- 'Parade'—Sweet-scented dark pink flowers with orange eye, July; wide upright; -24°F ; dark green leaves turn bronze-green and orange in fall; 6' by 4'.
- 'Pauline Bralit'—Mauve buds open to heavily textured, slightly fragrant white flowers in early May, large convex foliage, robust, 8'.
- 'Peach Blend'—Pink flowers with a yellowish center; early flowering, often ahead of forsythia; almost deciduous; 6'; 'Cornell Pink' $\times$ *R. keiskei*.
- 'Pillar'—Similar to *R.* 'P.J.M.', but more upright growing habit.
- 'Pillow Party'—See 'P.J.M. White Form'.
- 'Pink and Sweet'—Light pink flowers with a yellow flare in late June, rich spicy scent, bud hardy to -29°F , fall foliage is purple-red with tones of orange and yellow.
- 'PJM Caronella'—Strongest pink; holds about 30% of leaves in winter; fast growing to 6' by 3'; flower bud hardy to -18°F ; one of the Shrimp Pink hybrids, *R. minus* $\times$ 'Cornell Pink'.
- PJM Compact Form—Tetraploid form, flowers have greater substance and are much larger (2 to 3" diameter) than the diploid hybrid, trusses have 4 to 5 flowers and the truss is 4" wide by 2 1/2" high, leaves are broadly elliptic and are thicker and wider than the diploid form, stems are stout, erect, and thick, the plant habit is upright-spreading, and plants are bushy, hardy, flowers at the same time as 'P.J.M.'.
- 'P.J.M. Compact Briggs'—Lavender pink, smaller, tighter growth habit than 'Elite'.
- 'P.J.M. Lavender'—Hardy evergreen shrub, bright lavender pink flowers, early flowering, summer foliage green, winter leaves are reddish-brown to mahogany, semi-dwarf.
- 'P.J.M. Princess Susan'—Slow-growing, dwarf form, bright lavender purple flowers, deep mahogany-black winter foliage.
- 'P.J.M. White Form'—White-flowered counterpart to 'P.J.M.', small leaves turn rich mahogany red in winter, small clusters of white flowers in April, hardy, to 8' high and 5' wide.
- 'Popsicle'—Fragrant, dark pink flowers with orange flare; burgundy fall color; -35°F .
- 'Red Quest'—Light red flowers; small, dark green leaves; dwarf, compact to 4'.
- 'Red Splash'—Near-red flowers; rounded green leaves turn mahogany in winter; compact, slow-growing, 4'.
- 'Regal'—A selection of 'P.J.M.', vigorous, wider spreading type of growth.
- 'Ribbon Candy'—Spicy scented, pink flowers with distinctive stripes in late June, medium green summer foliage turns burgundy red in autumn.
- 'Scarlet Sorcerer'—Dark, clear red flowers; large, dark green leaves; to 8'; *R. catawbiense* selection.
- 'Shrimp Pink Hybrids' (*R. minus* var. *album* $\times$ *R. mucronulatum* 'Cornell Pink')—Green summer foliage turning light red in fall and retaining about 10% of the smaller leaves during the winter, upright-spreading habit of growth, flowers in abundance a week after *R. mucronulatum*, beautiful in flower at the Arnold Arboretum.
- 'Sparkler'—Ruffled dark pink flowers, spicy fragrance; blue-green leaves with glaucous underside; dark burgundy-purple in fall, deciduous; 6' high.
- 'Summer Rose'—Dark rose-pink flowers; long, dark green leaves; 8'; -18°F flower-bud hardiness.
- 'Tapestry'—Dark purple with darker eye; lustrous, dark green leaves; compact rounded-mounded; 6'.
- 'Thunder'—Rich dark pink-purple flowers in late April, lustrous leaves are black-mahogany during winter, changing to green after flowering, slightly slower and more compact than 'P.J.M.', to 5'.
- 'Trojan Warrior'—Dark purplish red flowers; dark green leaves; 8'.
- 'Trumpeter'—Salmon-pink.
- 'Vallya' ('Wally')—Soft pink flowers in mid-May, orange-red and yellow autumn tones color interior leaves before they drop in November, some of the long, leathery, dark green foliage is retained on the ends of the branches in winter, vigorous, wide-upright, growing to about 4' high and 2' wide in 8 years.
- 'Victor'—A selection of 'P.J.M.', a compact slow-growing type, earliest to flower.
- 'Victoria's Consort'—Ivory flowers; dark olive-green foliage; 8'.
- 'Waltham' (*R. ferrugineum* $\times$ *R. minus*, crossed by Dr. Robert Ticknor)—Deep green evergreen foliage on dense mound up to 3' high, flowers are pink *R. minus* type, beautifully displayed about a week later, leaves develop spotting when the plant is growing in full sun.
- 'Weston'—Pink flowers, Dexter hybrid; first large leaf rhododendron named by Weston Nurseries; 6'.

'Weston's Crescendo'—Pink flowers darker as they mature; low, wide, compact habit; 4'.

'Weston's Innocence'—Small, white flowers on a vigorous but compact, mounding shrub, flowers are sweetly scented, bud hardy to -29°F ; bronze-green foliage turns red in fall.

'Weston's Mayflower'—Pink, slow growing and compact, 4'; small green foliage all year.

'Weston's Pink Diamond' (A petaloid 'P.J.M.' hybrid $\times$ *R. mucronulatum* 'Cornell Pink')—Semi-evergreen foliage and upright-spreading habit; flowers early, at time of *R. mucronulatum*, with frilled pink heavily double flowers; 4' by 3' in 8 years, 8' at maturity.

'White Angel' (*R. minus* var. *album* $\times$ *R. dauricum* var. *album*)—Semi-evergreen, upright plant, pale lavender buds opening white as they mature.

'White Dimples'—White flowers; dark green leaves; 8'.

'Years of Peace'—Vigorous, upright habit; clear pink flowers; 8'.

Rhododendron prinophyllum (Small) Millais (formerly *R. roseum* auct.) — Roseshell Azalea
(rō-dō-den'dron prī-nō-fil'um)

Rhododendron prinophyllum is a deciduous, 4 to 8', rarely to 15' tall, much branched shrub with numerous spreading branches. Spread is comparable to height. Foliage is bright green in summer; green to bronze in fall. Flowers are bright pink with clove-like scent, May (April 24, 2004, Chapel Hill), borne 5 to 9 per cluster before or with the leaves. In this author's opinion superior to *R. periclymenoides* and *R. canescens*. Extremely hardy, with marked tolerance to high pH. 'Album' has fragrant, white flowers in late spring, 4' high and wide. 'Marie Hoffman' has larger flowers, clear true pink, extremely fragrant and cold hardy, 8' by 8', flowers late May. Native to New Hampshire and southern Quebec to Virginia, west to Illinois and Missouri. Introduced 1812. Zone 4 to 8.

Rhododendron prunifolium (Small) Millais — Plumleaf Azalea
(rō-dō-den'dron prō'ni-fō'li-um)

Rhododendron prunifolium grows 8 to 10'(15') high and produces orange-red to red, funnel-shaped, 3/4 to 1" long flowers in July–August. The stamens are 2 to 2 1/2" long. The lateness of flower makes this a rather valuable addition to the garden. It is hardy to Boston but makes its best growth in the South and can be found in abundance at Callaway Gardens, Pine Mountain, GA. It is considered the most glabrous of all American azaleas and for that reason quite distinct. Found in sandy ravines along stream banks. Flowers in July in Dirr garden with flowers nestled among leaves. Tends to lose some of its pizzazz due to foliar competition but still beautiful. Southwestern Georgia and eastern Alabama. Introduced 1918. Zone 5 to 8.

Cultivars include:

'Apricot Glow'—A selection of the plumleaf azalea with orange flowers in late July, wide and upright-growing, rounded dark green foliage.

'Cherry Bomb'—Orange-red, July.

'Coral Glow'—Pink-orange, July.

'Lewis Shortt'—Scarlet red flower on a plant with plum leaf foliage, found and introduced by Mr. Shortt.

'Peach Glow'—Orange-pink, July.

'Pine Prunifolium'—Bright red flowers open in mid summer.

Rhododendron 'Purple Gem' is a rounded, dwarf, evergreen type with small leaves and light purple flowers in mid-April. Hardy to -15°F . A cross between *R. fastigiatum* $\times$ *R. minus*. 'Purple Imp' is similar to 'Purple Gem' but a truer blue; smaller and more alpine, low and dense.

Rhododendron racemosum Franch. 'Compactum'
(rō-dō-den'dron ra-sem-ō'sum)

Rhododendron racemosum 'Compactum' is a compact form, 1 to 2' high, apple blossom pink, a rock garden gem. Species is native to western China. Introduced 1889. Zone (5)6.

Rhododendron 'Ramapo' is another compact form with glaucous foliage, bright violet-pink flowers in early April and -25°F hardiness. 'Ramolet' has light lavender flowers, tidy upright habit, long slender leaves.

Rhododendron serrulatum (Small) Millais — Sweet Azalea
(rō-dō-den'dron ser-ū-lāt'um)

Rhododendron serrulatum is a medium to large-growing azalea, one of the late flowering azaleas with flowers occurring after the foliage, from June through July. Flowers are 1 to 1 1/2" long, from pale pink to white and exceptionally fragrant. In author's garden, not overwhelming. Does well in wooded swampy areas. Merged with *R. viscosum*. Georgia to Florida and Louisiana. Introduced 1919. Zone 7 to 8.

Rhododendron smirnowii Trautv. — Smirnow Rhododendron
(rō-dō-den'dron smēr-nōw'ē-ī)

Rhododendron smirnowii is an evergreen shrub growing 6 to 8' high and as broad in 15 years. The foliage, 4 to 6" long, oblong-ovate, is dark green above with thick woolly tomentum beneath. The bell-shaped flowers are rose or rosy-pink and the corolla is frilled; each flower is 1 1/2" long and 2" across; May; in 5 to 6" wide trusses. Very distinct and handsome rhododendron in flower. Has been used for breeding work because of good hardiness (Zone 4), flower and foliage. Becoming more evident in American gardens as its merits are extolled. Native to Caucasus at 5,000 to 8,000' elevation. Introduced 1886.

Rhododendron vaseyi A. Gray — Pinkshell Azalea
(rō-dō-den'dron vā'zē-ī)

Rhododendron vaseyi grows 5 to 10' in height. The habit is irregular upright. Foliage is deciduous, medium green in summer changing to light red in fall, may develop excellent fall color and have observed deep red on plants in Arnold Arboretum. Flowers are clear rose, bell-shaped with the two lower corolla lobes divided nearly at the base, before leaves, 1 1/2" diameter, early to mid-May, 5 to 8 flowers per inflorescence, 5 to 7 stamens, no fragrance, non-sticky corolla. One of the hardy American types. Makes a spectacular show when in flower. Apparently does not hybridize. Native to the Blue Ridge Mountains of North Carolina. Zone 4 to 7. Not as heat tolerant as *R. austrinum*, *R. canescens*, *R. alabamense*, and *R. prunifolium*.

Cultivars include:

- 'Album' (var. *album*)—White flowers.
- 'Pinkerbell'—Selected deep pink strain of the species.
- 'White Find'—A rare form, the white flowers have a greenish yellow blotch and are fragrant.

Rhododendron viscosum (L.) Torr. — Swamp Azalea
(rō-dō-den'dron vis-kō'sum)

Rhododendron viscosum grows 1 to 8' (average 5') by 3 to 8' and is of loose, open habit with numerous spreading, very hispid branches. Flowers are white, rarely pink, clove-like scent, mid May to June, 4 to 9 flowers per inflorescence. Have seen it growing along fresh water ponds on Cape Cod. Leaves are lustrous green sometimes with a glaucous cast below. Maine to South Carolina, Georgia, Alabama, in swamps. Cultivated 1734. Zone 4 to 9.

Cultivars include:

- 'Antelope'—A cross of *R. viscosum* and *Mollis*, with excellent hardiness and strong fragrance, the clear pink flowers are marked with a darker pink median line and a faint yellow flare giving them a salmon glow.
- 'Arpege'—Warm yellow azalea with an even deeper yellow flare on the upper petal, superior fragrance, late flowering.
- 'Delaware Blue'—Blue-green leaves, fragrant flowers are pure white with a very narrow, tubular-shaped opening from softly pink-shaded buds.
- 'Jolie Madame'—Beautiful rose-pink, fragrant flowers with golden blotch in late May–June.
- var. *montanum*—A low-growing form only waist high, is responsible for many of the natural hybrids as it flowers with other species in June.
- 'Pink Mist'—A fragrant, white tinged pink selection.
- 'Pink Rocket'—Red buds, slightly sweetly scented groups of small, pink flowers in late June, wide, upright-growing, small ascending blue-green foliage with silvery undersides, turns bronze-red in fall, –29°F.
- 'Rosata'—Fragrant carmine-rose flowers, wide, upright.
- 'Soir de Paris'—Fragrant, dark rose flowers with a brilliant orange blotch.

Rhododendron weyrichii Maxim. — Weyrich Azalea
(rō-dō-den'dron wār-ich'ē-ī)

Rhododendron weyrichii is a most unusual and beautiful deciduous azalea. Foliage is large, broad ovate to rounded and glossy with clusters of 2 to 3 leaves at end of the branches; turning vinous purple in autumn. Funnel-shaped flowers usually brick-red with purple blotch adorning the plant before leaves appear in early spring. Native of Quelpaert Island, Korea, Japan. Introduced 1914. Zone 6.

Rhododendron 'Windbeam' is another very hardy (–25°F) evergreen type of low, semi-dwarf habit, with white flowers becoming suffused with pink. It is a cross between *R. minus* and *R. racemosum* and will grow 4' by 4'. Leaves are roundish, small and aromatic. In Zone 7, foliage remains green in winter. In the 1983 Edition, I did not have much positive to say about performance in Zone 7 but over the past 26 years have altered my assessment. If given pine shade and a moist, well-drained root run, it makes a handsome plant. 'Manita(o)u' is more compact in growth habit, small, dark green, rough-textured leaves, light pink flowers, will withstand sun.

Rhododendron yakushimanum Nak. (now *R. degronianum* Carr. subsp. *yakushimanum* (Nak.) Kitam.)
(rō-dō-den'dron ya-kōsh-i-mā'num)

Rhododendron yakushimanum is a dense, mounded, evergreen rhododendron growing about 3 to 5' tall and 3 to 5' wide. The foliage is dark green with a woolly indumentum beneath. The flowers are bright rose in bud opening to white in full flower (sort of an apple blossom effect), about 10 campanulate flowers in a truss; hardy from -5 to -15°F. Used extensively in hybridizing and superior clones are available. One reference indicated a 20-year-old plant may be only 3' by 5'. The search of literature and nursery catalogs uncovered over 118 named selections or hybrids with *R. yakushimanum* as a parent. 'Ken Janeck' is dwarf, compact, to 3', with prominent, distinctive, silver-white flower buds all winter; open to pale pink, mature pure white in May; 2002 winner of Cary award. See Neil Lancaster, *Rhododendron yakushimanum* & hybrids, *RHS Plant Bulletin* 13, May 2006. Mountain peaks of Yakushima Island, Japan. Introduced 1934. Zone 5 to 6.

Rhododendron yedoense Maxim. var. ***poukhanense*** (H. Lev.) Nak. — Korean Azalea
(rō-dō-den'dron yed-ō-en'sē pōk-ha-nen'sē)

Rhododendron yedoense var. *poukhanense* grows 3 to 6' high and spreads that much or more. Develops into a broad mat on exposed locations. Foliage is dark green in summer; orange to red-purple in fall. Flowers are rose to lilac-purple, 2" across, slightly fragrant, May, 2 to 3 flowers together. 'Pink Discovery' has clear pink flowers. *Rhododendron yedoense* (Yodogawa Azalea) has double flowers of a similar color. Long cultivated in Japan and Korea. Cultivated 1886. Native to Korea. Introduced 1905. Zone (4)5 to 7. Has performed well in Illinois and Athens, Georgia.

Azalea Cultivars and Hybrid Groups

In some respects, it is paralyzingly frightening to attempt to present the cultivars of azaleas. Numerous hybridizers using different progenitor species have produced hybrids that often bear their names. Mr. Fred Galle, in his great book *Azaleas* (1987), Timber Press, Portland, OR, presents the most comprehensive and up-to-date listing and description of azalea cultivars. I attempted to check the ones presented here (most derived from 1987-89 nursery catalogs for 1990 Edition, 1996-98 nursery catalogs for 1998 Edition) against Mr. Galle's list. Many did not appear in his book. About 30 catalogs plus current literature were used to assemble the 1998 list. For the 2009 edition, I added/expanded cultivar treatment based on what hybridizers are creating and what makes its way into commerce. When Mr. Robert ("Buddy") Lee created the Encore® Azaleas, he forever changed the thinking about marketing evergreen azaleas. Now there was a group of azaleas that flowered in spring and late summer-fall and would command a respectable price. Azaleas, particularly in the South, are treated as loss leaders, 10 for \$25.00 at retail. Production nurseries cannot produce them for that price.

I speculate many of those sold in spring do not persist in the garden. Akin to a woody annual, but still beautiful.

Anyone interested in azaleas, their history and development should consult Mr. Galle's book. It is the classic tome on the subject.

AICHELE HYBRIDS (Azaleas)

Developed in South Carolina from 10,000 seedlings over 8 years as greenhouse-forcing cultivars.

'Laura'—Originally developed as a greenhouse forcing azalea, dense foliage and abundant, dark pink, 2" diameter hose-in-hose flowers in early April, hardy in Zone 7 to 8.

'Posaman'—Medium-sized shrub with 3" diameter, pink-white flowers.

AROMI HYBRIDS (Azaleas)

Unable to grow Exbury Azaleas because of their intolerance of hot summers, but still determined to have Azaleas with incandescent flowers and large flower trusses, the late Dr. Eugene Aromi of Mobile, AL, embarked on an undertaking to breed native heat tolerant species with Exbury Hybrid Azaleas, and his labors have produced Azaleas with lavish flowers as well as heat and cold hardiness. These hybrids flower in early May, but beyond that, they look good all season, and the foliage has never been disfigured by mildew at the end of the summer. Plant these azaleas in full sun or light shade. Dr. Aromi's original plants now measure about 12 to 15' high and tend to be upright growing. Very heat tolerant.

'Aromi Sunny Side Up'—Rich golden yellow flowers carry an egg yolk yellow flare.

'Aromi Sunrise'—Numerous trusses of large flowers with orange-red buds that open light orange and gradually shade to darker orange in the center, the dark green foliage remains handsome all season.

'Carousel' (PP16,783)—Scarlet buds open to delicate, ruffled flowers colored pale pink and marked with a prominent gold blotch, the large trusses bear several flowers, medium-green foliage, healthy foliage.

'Centerpiece'—Large, white flowers with a deep yellow blotch.

- 'Clear Creek'—Long, tubular flowers are a lovely translucent yellow with a discreet, darker yellow blotch.
- 'Frontier Gold'—Orange-scarlet buds open to rich gold flowers with scarlet shadings.
- 'High Tide'—Delicately colored, ivory flowers with a gold flare and a pale overlay of blush pink at the tips.
- 'Jane's Gold'—Frilly, creamy yellow flowers with tips lightly washed with rose.
- 'Liz Colbert'—This pastel-colored release extends the color range of these hybrids, brick-colored buds open to light peach flowers with a light orange flare.
- 'LN'—Beautiful light pinkish yellow flowers with a pronounced fragrance are displayed on a small to medium-sized shrub.
- 'Sun Struck'—Pale yellow buds open to lemon yellow flowers with a darker blotch.

BACK ACRE HYBRIDS (Azaleas)

Plants are cold hardy to 0 to 5°F, flowers open in late April in Georgia, medium-sized shrubs.

- 'Marian Lee'—Flower has white center with reddish pink border, 3" diameter with the appearance of butterflies, medium-sized upright grower, habit similar to the Kurumes.
- 'Orange Flair'—Low-growing plant with very unusual flower, orange-pink with a white center and double.
- 'Pat Kraft'—Single, 3" diameter, scarlet red with a rose blotch, 6-lobed flower, low-spreading habit.
- 'Target'—Scarlet-pink, 3" diameter flowers, upright grower.

BELTSVILLE (YERKES-PRYOR) HYBRIDS (Azaleas)

Developed by USDA starting in 1950. Zone 7 to 9, but certainly 6 for some cultivars.

- 'Casablanca'—Outstanding, single, white flowers, grows wider than high.
- 'Casablanca Improved'—Large, single, white flowers.
- 'Eureka'—Flowers pink, hose-in-hose, medium, spreading.
- 'Guy Yerkes'—Salmon-pink, hose-in-hose, low growing, semi-evergreen.
- 'H.H. Hume'—White, 2" diameter, hose-in-hose flowers with faint yellow throat, flowers in clusters of 3 or 5, mid-season, 6' by 6'.
- 'Placid'—White flowers with a slight green tinge, hose-in-hose, low, compact, spreading plant, hardy.
- 'Polar Bear'—White, with slight yellow-green throat, hose-in-hose, wide upright, slow-growing, green leaves in summer become yellow in autumn, flower buds tested hardy to -13°F, common in the trade.

BROOKS HYBRIDS (Azaleas)

Developed to endure hot, dry summers, hardy to 20°F. Developed in Modesto, CA using Southern Indica and Kurumes. Medium-sized to 4 to 6'.

- 'Flamingo Variegata'—Variegated red, hose-in-hose, late.
- 'My Valentine'—Rose, double, mid to late season.
- 'Pinkie'—Pink, hose-in-hose, late.
- 'Red Bird'—Large, red, ruffled, semi-double to hose-in-hose.

CARLA HYBRIDS (Azaleas)

Developed at North Carolina State University, Raleigh, NC, Zone 7–8. Flowering dates are based on observations in the Raleigh area. In 1976, 'Adelaide Pope', 'Carror', 'Elaine', 'Emily', 'Jane', 'Spalding', 'Pink Cloud', and 'Sunglow' were released. In 1982, 'Autumn Sun', 'Cochran's Lavender', 'Pink Camellia', and 'Wolfpack Red' were released. Evergreen, bred for *Phytophthora* resistance. Grew several in Dirr garden, all disappeared, terrible lace bug in Dirr garden.

- 'Adelaide Pope'—Flowers deep rose-pink, single, medium-large, 1 to 5 per bud, plant medium-large, vigorous, compact, April 15–April 25.
- 'Autumn Sun'—Flowers bronze-red, hose-in-hose, 2 to 3 per bud, plant small to medium, upright-spreading, dense, April 15–25.
- 'Carror'—Flowers rose-pink, semi-double, medium-sized, 1 to 4 per bud, plant medium-sized, compact, April 25–May 1.
- 'Cochran's Lavender'—Flowers purplish pink, single, medium-sized, 1 to 3 per bud, plant medium-sized, spreading, dense, April 15–25.
- 'Elaine'—Flowers light pink, fully double, medium sized rose-bud type opening full wide in later development, 1 to 3 flowers per bud, plant medium-sized, April 16–26.
- 'Emily'—Flowers deep rose-red, single, medium-small, 1 to 3 per bud, hose-in-hose, plant medium sized, compact, April 18–30.
- 'Fred D. Cochran'—Superior resistance to root rot.
- 'Greenthumb Peppermint'—Mid to late flowering, semi-double, hose-in-hose, 3" diameter pinkish with white margins and a soft purplish pink inner pattern, typically plants develop sports of white and purplish pink, see *HortScience* 25: 236-237 (1990), not a Carla hybrid, but introduced through North Carolina State.

- 'Jan Cochran'—Compact shrub that resembles an English Boxwood in leaf, single rosy pink, 4/5 to 1" long, 3/5 to 4/5" wide, moderately resistant to *Phytophthora cinnamomi*, see *HortScience* 24: 717-718 (1989).
- 'Jane Spalding'—Flowers rose-pink, single, 1 to 3 per bud, medium-sized, plant is medium-sized, April 25–25.
- 'Pink Camellia'—Flowers light purplish pink, completely double, rosebud type, opening full in later development, 1 to 3 flowers per bud, plant medium-sized, April 15–25.
- 'Pink Cloud'—Flowers light pink, predominantly single, large-sized, 2 to 4 per bud, plants medium-sized, April 15–25.
- 'Rachel'—Compact shrub with ascending-spreading branches, wine-red flowers, single to semi-double, up to 2" diameter, 40 to 50% of the flowers are semi-double, moderately resistant to *Phytophthora cinnamomi*, see *HortScience* 24: 717-718 (1989).
- 'Sunglow'—Flowers deep rose-pink, single, medium large, 1 to 4 per bud, plant medium-large sized, vigorous, April 20–30.
- 'Wolfpack Red'—Flowers strong red, single, small, 1 to 4 flowers per bud, plant semi-dwarf, spreading, April 15–25.

CONFEDERATE SERIES/TOM DODD, JR AND SON HYBRIDS (Azaleas)

Alabama plantsmen Bob Schwind, Tom Dodd, Jr. and Tom Dodd III have crossed the Exbury Azalea 'Hotspur Yellow' with *R. austrinum* to produce the heat and cold tolerant hybrids. All of these azaleas also have a pleasant fragrance. Zone 6 to 9.

- 'Admiral Semmes'—Large inflorescences of big, fragrant, yellow flowers, named for Civil War Admiral and General Raphael Semmes for whom the town Semmes, AL was named; great doer in Dirr garden, this is one of the most floriferous, flowers in mid-April; also, easy to root.
- 'Col. Mosby'—Big inflorescences of large, fragrant flowers that start deep pink and fade to lighter pink with a yellow blotch.
- 'Emma Samson'—Pink with yellow-white center, not a well-formed flower; fragrant; grew in Dirr garden.
- 'General N.B. Forrest'—Large, ruffled, red-orange, fragrant.
- 'J.E.B. Stuart'—Large, dark pink, fragrant, late.
- 'Robert E. Lee'—Fragrant, red ruffled flowers in spring.
- 'Stonewall Jackson'—Fragrant, orange flowers in spring, first to open; akin to 'Gibraltar' but more heat-tolerant.

COOLIDGE HYBRIDS (Azaleas)

Introduced in 1930s from Pasadena, CA; some with *R. mucronatum* parentage; Zone 7 to 9.

- 'American Beauty'—Double, holly berry red.
- 'Singing Fountain'—Single, rose-cerise.

ENCORE® HYBRIDS (Azaleas)

Unique for fall flowering, in the Dirr garden late August–September into November, again in April–May. Not particularly cold hardy as a group, best in Zone 7 to 9 with probably some cultivars functioning in 6. Based on two complete growing seasons in the Dirr garden, Autumn Coral™, Autumn Embers™, Autumn Rouge™, and Autumn Royalty™ were the most vigorous, cold hardy, and floriferous. Bred by Robert E. Lee. Introduced by Flowerwood Nursery, Mobile, AL. The cultural conditions of the Encore Azaleas are similar to Satsuki Azaleas. Should be planted in well-drained, slightly acidic soil, with light shade or afternoon shade. Have not observed as much lace bug damage on the Encore® series as on the Kurumes, Satsukis, etc . . .

Autumn Amethyst™ ('Conlee', PP 10,567)—*Rhododendron oldhamii* × *Rhododendron* 'Karens', the most cold hardy of the Autumn series, foliage is elongated, pointed and rough-textured, leaves take a beautiful dark cast in the winter, soft purple flowers, intermediately dense and spreading habit, flowering begins early fall.

Autumn Angel™ ('Robleg', PP 15,227)—Pure white flowers; glossy, deep green foliage.

Autumn Belle™ ('Robleo', PP 19,899)—Light green foliage; ruffled pale pink flowers embellished by delicate white lacing and magenta freckles.

Autumn Carnation™ ('Roblec', PP 15,339)—Rich medium pink blooms; lustrous dark green foliage.

Autumn Carnival™ ('Conlet', PP 12,111)—Brilliant, medium pink blooms.

Autumn Cheer™ ('Conlef', PP 10,579)—*Rhododendron oldhamii* × *Rhododendron* 'Pink Cheer', foliage, growth habit and flowers look like a Kurume type azalea, flowers are slightly larger than Kurume flowers and are deep pink, the most compact of the Autumn cultivars, flowering is from early August through the fall.

Autumn Chiffon™ ('Robled', PP 15,862)—Light pink flowers with a splash of dark pink in the center.

- Autumn Coral™ ('Conled', PP 10,568)—*Rhododendron oldhamii* × *Rhododendron* 'White Gumpo', mounding habit, flowers abundantly from July through the fall, flowers are salmon pink with prominent fuchsia flecking and medium in size.
- Autumn Debutante™ ('Roblel', PP 16,278)—Lustrous dark green foliage; delicate, light pink flowers.
- Autumn Embers™ ('Conleb', PP 10,581)—*Rhododendron oldhamii* × *Rhododendron* 'Watchet', low, spreading and dense habit, foliage is dark green, flowering is from early July through the fall and very intense, single and semi-double, deep orange-red flowers, fall flowering is profuse.
- Autumn Empress™ ('Conles', PP 12,109)—Dark green foliage; medium pink flowers.
- Autumn Monarch™ ('Conleo', PP 11,640)—Light green foliage; ruffled blooms in shades of orange-pink and specks of red.
- Autumn Moonlight™ ('Robler', PPAF)—Ruffled flowers are pure white with yellow dusted throats; light green foliage.
- Autumn Princess™ ('Roblea', PP 12,142)—Salmon, double flowers during the winter; foliage turns a gorgeous burgundy.
- Autumn Rouge™ ('Conlea', PP 10,438)—*Rhododendron oldhamii* × *Rhododendron* 'Double Beauty', the breeder's favorite, very prolific, flowering from early July through the fall, semi-double, strong pink almost red flowers, upright habit.
- Autumn Royalty™ ('Conlec', PP 10,580)—*Rhododendron oldhamii* × *Rhododendron* 'Georgia Giant', robust, upright and globose, large, dark green foliage, flowers from late July to frost, flowers are large, single, rich purple.
- Autumn Ruby™ ('Conler', PP 12,110)—Petite, ruby-red flowers.
- Autumn Sangria™ ('Roblee', PP 15,077)—Largest, dark pink flowers.
- Autumn Starlight™ ('Roblem', PP 15,043)—Pink flecks and an occasional pink strip add bursts of color to the otherwise white flowers; light green, narrow leaves.
- Autumn Sundance™ ('Roblef', PP 16,184)—Deep pink flowers; rich green foliage turns reddish in winter.
- Autumn Sunset™ ('Roblen', PP 16,248)—Orange-red flowers; deep green foliage.
- Autumn Sweetheart™ ('Robleja', PP 16,249)—Pink flowers so soft almost white, dotted with lavender freckles.
- Autumn Twist™ ('Conlep', PP 12,133)—White- and purple-striped flowers, occasionally, a complexly purple one will appear; dark green foliage.

GIRARD HYBRIDS (Azaleas and Rhododendrons)

Excellent, large-flowered, show-stopping evergreen (also deciduous types) azaleas and rhododendrons for colder climates. Flower bud hardiness ranges from −5 to −15°F. Grew many of these in our Illinois garden, need more attention from northern gardeners. Foliage is among the most handsome of the evergreen azaleas. Bred and introduced by Girard Nurseries, Geneva, OH.

'Girard Artic Rose'—Variegated-leaf form of 'Girards Rose'.

'Girard Arista'—Beautiful large deep pink flushed to light pink with a deep orange-yellow blotch, heavily ruffled, fragrant trusses up to 6" across, dense habit with deep green foliage, mildew resistant, very early flowering.

'Girard Better Letter'—Outstanding deep orange-red flowers and vigorous growth, hardy to −15°F.

'Girard Border Gem'—Beautiful deep rose-pink flowers that completely cover the dwarf azalea, when in flower, the foliage and plant are completely hidden; leaves are glossy dark green, only 1/4 to 3/4" long, turning a glossy scarlet during winter months; an early flowering beautiful dwarf azalea, 2' by 3'?

'Girard Caitlin'—Apple-blossom pink flowers, edged in darker pink, centers light pink; clean light green foliage; compact evergreen habit, 3' by 3'.

'Girard Caroline'—Solid rose-red, 1 1/2 to 2" diameter flowers; compact self-branching, prolific flowering, excellent dark green foliage that takes on a reddish cast in winter; longer flowering period than most; 3' by 3'.

'Girard Clare Marie'—Large ruffled single white flowers up to 3" in diameter, very vigorous upright grower, large light green foliage.

'Girard Chiara'—Flowers are large, hose-in-hose, 2 1/2 to 3" diameter, color is clear rose, pleasingly ruffled and very floriferous; foliage is glossy deep green type which holds very well; plant takes on a dense broad growing habit, ideal for borders, foundation planting and rock gardens, will withstand −15°F, ideal for forcing; originated in 1972.

'Girard Constance'—Hose-in-hose, bright salmon flowers, prolific flowering as blooms literally smother the foliage; medium green foliage; 3' by 4'.

'Girard Crimson'—Large crimson flowers up to 2 1/2" diameter, large glossy green leaves, good winter color, on a compact plant.

'Girard Crimson Tide'—Large double red flowers on a tight round head, vigorous grower and excellent flowerer.

- 'Girard Custom White'—Large, white, ruffled flowers, 2 1/2 to 3' across; medium green foliage; 3 to 4' by 3 to 4'.
- 'Girard Dwarf Lavender'—Medium clear lavender flowers, one of the most uniform and compact growing of all the evergreen azaleas; excellent foliage, vigor and hardiness, needs little pruning, excellent for small gardens; 1 1/2 to 2' by 1 1/2 to 2'.
- 'Girard Fireflash'—Large, 2 1/2" diameter, beautiful deep orange-red flowers with an orange-yellow throat, hardy, flowers profusely mid to late season.
- 'Girard Fuchsia'—A beautiful shade of reddish purple, flowers are beautifully waved and ruffled and heavy-textured, foliage dark green and glossy, -15°F; 3 to 4' by 3 to 4'.
- 'Girard Hotshot'—Fiery deep orange-red or scarlet flowers, 2 1/2 to 3" diameter, heavily textured and completely covering the plants, foliage 3/4 to 1" long, medium green during summer changing to brilliant orange-red in fall, more upright habit than 'Girard Scarlet', 2 1/2 to 3' by 3'.
- 'Girard Jeremiah'—Prolific, beautiful large hose-in-hose pink flowers, large dark green foliage turning red in winter, excellent compact self-branching habit; 2 1/2 to 3' by 3'.
- 'Girard Joshua'—Beautiful dark red, ruffled flowers with white stamens and pistils, compact, medium height, wavy large green leaves, leaves similar to 'Nova Zembla' but darker and more heavily foliated, later flowering than 'Girard Sandy Petruso', bud hardy -15°F, height 5 to 6', named by Peter Girard, Sr. for his great grandson.
- 'Girard Kathy Ann'—Good 2" diameter, single, white flowers on a medium-sized shrub, 3 to 4' by 4'; have been listed as 'Girard Kathy'.
- 'Girard Leslie's Purple'—Large hose-in-hose purplish red flowers with dark spotting, 2 1/2 to 3" diameter, foliage deep glossy green, semi-dwarf, low compact rounded habit, 3' by 3'.
- 'Girard Little Aimee'—Red flowers, early spring; tiny leaves; small compact habit; "witches'-broom" from 'Hot Shot'; 15" by 15".
- 'Girard Little Michelle'—Clear pink, 1 1/2 to 2" diameter flowers, late season flowers; small, medium green leaves, 1 1/2' to 2' by 2 1/2 to 3'.
- 'Girard Lucky Star(s)'—Buds pink opening to pure white with a light cream center, ruffled flower, compact growing.
- 'Girard Mount Saint Helens'—A blend of pink, salmon, with yellow and orange blotch exploding from all copper flower petals, very large trusses, 5" by 6", holding 12 to 15 large flowers of heavy texture, upright with good foliage that holds well until winter.
- 'Girard National Beauty'—Beautiful ruffled rose-pink flowers, large dark green foliage and compact self-branching growth habit, matures to 24" high, 3' wide, hardy to -10°F.
- 'Girard Orange Jolly'—Large, double, bright orange flowers growing in large ball-like truss, sterile with no seed capsules, vigorous growing, to 6', hardy to -25°F.
- 'Girard Peter Alan'—Rich orchid flowers with reddish shading to purplish black eye, strong upright habit, foliage is heavy rich green, hardy to -15°F.
- 'Girard Pink Dawn'—Large, hose-in-hose, rose-pink, foliage is dark green in summer and assumes red tints in fall and winter, compact and vigorous, one of the hardiest.
- 'Girard Pink Delight'—Fragrant, hose-in-hose, vivid pink with 20 to 24 flowers forming a nice compact truss, tall growing.
- 'Girard Pleasant White'—Large, 1 1/2 to 3" diameter, white flowers with a cream center, late flowering and vigorous, 2 to 2 1/2' by 3', dark green foliage, hardy.
- 'Girard Purple'—Purple flowers, superior color and habit compared to 'Herbert' or other lavenders, extremely vigorous and compact growing.
- 'Girard Red Pom Pom'—Fragrant, double red, forming a tight long-lasting truss, 3 1/2" long and 4 1/2" wide, compact, mildew resistant plant.
- 'Girard Remarkable Pink'—Bi-color pink with white center flowers, ball-shaped trusses, mid-season, medium habit, 4'.
- 'Girard Renee Michelle'—Clear pink flowers, 2 1/2 to 3", foliage dark green, 1 1/2" by 1/2", plants are low, compact, a cross of 'Boudoir' and 'Gumpo Pink', beautiful flowers, flowered in my Illinois garden in a protected location, has withstood -10°F.
- 'Girard Roberta'—Double pink, ruffled petals, large to 3" across.
- 'Girard Rose'—Rose, 2 1/2 to 3" flowers, slightly wavy, foliage 1 1/2 to 2" long by 3/4" wide, glossy deep green during the summer, taking on brilliant deep red tints in early fall, stems turn deep red in winter, vigorous, upright growth habit.
- 'Girard Ruffled Red'—Rose-red, heavily ruffled flowers in tight trusses that sit flush to the foliage, leaves are heavy-textured and plant is vigorous upright growing, hardy.
- 'Girard Salmon'—Large, hose-in-hose, salmon flowers, compact habit, more upright and taller than most Girard selections, vigorous.
- 'Girard Salmon Delight'—Vivid rose flushed with yellow, flowers 2 to 1/2" diameter with 25 to 30 flowers to each 5 to 5 1/2" diameter truss, leaves medium green turning to yellow with orange tints, broad upright growth habit, appears mildew resistant.

- 'Girard Sandra Ann'—Reddish purple, 3" diameter flowers, bright green foliage, broad rounded habit, 5' by 6'.
- 'Girard Sandy Petruso'—Gorgeous, bright fire-engine red, large trusses, semi-upright habit, large deep green leaves, sister seedling to 'Joshua', height to 7', bud hardy to -10°F.
- 'Girard Saybrook Glory'—Large pink flowers, 2 1/2 to 3" ruffled flowers, large dark green foliage, low compact plant.
- 'Girard's Scarlet'—Large flowers, strong red with deep orange-red glow, waxy textured, deep glossy green foliage, low compact plant, 1 1/2 to 2' by 3'.
- 'Girard The Robe'—Large, 2 1/2 to 3", pink flowers, bright green foliage with white margin, dense, somewhat upright shrub, 3 to 5' high.
- 'Girard Unsurpassable'—Rose-pink flowers, compact with good dark green foliage, hardy.
- 'Girard Variegated'—Lipstick orange-red flowers, mid-spring, white-variegated foliage, low semi-deciduous shrub.
- 'Girard Variegated Gem'—Bright rose-pink flowers, profuse flowering, a beautiful dwarf, 24" by 30" high, leaves are wavy, narrow, with a white margin along its edge, has more definition than other variegated azaleas.
- 'Girard Variegated Hotshot'—White- and green-variegated foliage and ruffled red flowers similar to 'Hotshot', a vigorous low compact plant.
- 'Girard Wedding Bouquet'—Unique apple blossom pink hose-in-hose frilled flowers, 18 to 25 per truss, fragrant, medium growing.
- 'Girard White Clouds'—Seedling white, vigorous.
- 'Girard Yellow Pom Pom'—Large, beautiful, double, fragrant, yellow flowers, forming a tight high truss approximately 5" across and 3 1/2" high, early May, long lasting, compact habit, some mildew resistance.

GLENN DALE HYBRIDS (Azaleas)

Cold hardy for the Middle Atlantic States with flowers as large and as varied as those of the Southern Indica Azaleas! That was the aim of B.Y. Morrison, former head of the Plant Introduction Section at Glenn Dale, MD. The project began around 1929. To achieve that goal he selected and named 454 Glenn Dale Hybrids from 70,000 seedlings. Some of the hardiest will withstand -10°F, however, they are often listed as flower bud hardy to 0°F. Flower from (April in Zone 7) May into June. Many have flecks or occasional stripes of a deeper complementary color that add considerable visual interest. Some will sport and produce branches with flowers that can be distinctively different in pattern and color. Parentage is varied with *R. indicum*, *R. simsii*, *R. yedoense* var. *poukhanense* as well as Kurume and Southern Indicas in the mix.

- 'Alight'—Orange-pink.
- 'Amy'—Pink flowers in spring, vertical habit, 6'.
- 'Angela Place'—Pure white, wide open flowers with almost no blotch, late May into early June, dark glossy green leaves, spreading to 4'.
- 'Aphrodite'—Rose-pink, single, 2" diameter flower.
- 'Artic'—White.
- 'Aztec'—White.
- 'Baroque'—White flowers with striping of phlox-purple, broad-spreading, to 5' high, dark green leaves.
- 'Beacon'—Scarlet.
- 'Boldface'—White center with lavender margin.
- 'Bountiful'—Frilled, phlox purple flowers, early June, bushy habit to 4'.
- 'Bridal Veil'—Starry white flowers with a touch of green on the upper lobes, early May, to 5'.
- 'Buccaneer'—Orange-red.
- 'Burgundy'—Deep burgundy red, a little later than 'Carmel' in early May.
- 'Cadenza'—White with purple flecks, mid-season.
- 'Carmel'—Spinel red with a blotch of Indian red dots, carries in garden effect as a burgundy red, very effective as accents to masses of light colors, tall and spreading.
- 'Cascade'—White, spotted rose-pink, hose-in-hose, 1 1/2" diameter, 4' by 4 to 6'.
- 'Colleen'—Pink.
- 'Copperman'—Orange-red, single flowers on medium-size, spreading, dense plants.
- 'Dayspring'—Pink.
- 'Delaware Valley White'—White, single, 2" diameter; one of the more common forms in commerce; mid-season; was told by the late Carl Orndorff, Maryland, that this is not a Glenn Dale and was one of his introductions.
- 'Delilah'—Begonia rose.
- 'Delos'—Rose-pink.
- 'Dimity'—Flowers are 2" wide in combinations of reddish pink stripes and flecks on white, upright-spreading plant.

- 'Dragon'—Extremely floriferous, brilliant red with flowers 2" across, dense and twiggy habit to 5', mid-season.
- 'Driven Snow'—Pure white flowers, 6' high.
- 'Eros'—Pink.
- 'Evensong'—Rose-pink.
- 'Everest'—White with pale chartreuse blotch, floriferous, 5' high.
- 'F.C. Bradford'—Deep rose-pink with darker edges, blotch of purplish red dots, 5' high.
- 'Fanfare'—Pink, hose-in-hose.
- 'Fashion'—Two inch diameter orange-red, hose-in-hose flower, medium-sized shrub, 6' by 6', 0°F.
- 'Fawn'—White center, pink margin.
- 'Festive'—White striped with red.
- 'Glacier'—White petals with faint green tone to the throat, to 3" in diameter, vigorous grower to 6', erect to spreading habit, handsome lustrous foliage, one of the best Glenn Dale's, used frequently in the South.
- 'Gladiator'—Orange-red.
- 'Glamour'—Rose-red flowers 2 to 3" across, mid-April to early May, dark green leaves turn bronze in fall.
- 'Grace Freeman'—Pale pink.
- 'Greeting'—Ruffled coral-rose flowers, glossy dark green persistent leaves, erect-spreading, to 4' high.
- 'Guerdon'—Light lavender with a lavender-rose blotch, low-spreading, to 2' high.
- 'Helen Close'—Large, white flowers open with a very pale yellow blotch which fades to white, habit is dense and twiggy to 4', mid-season.
- 'Helen Fox'—Light pink with irregular white margins, mid-June.
- 'H.H. Hume' (USDA, Beltsville hybrid)—White, with faint yellow throat, hose-in-hose, erect-spreading habit, 0 to 10°F.
- 'Illusions'—Lovely soft shades of pink, one of the hardiest, to 3' high.
- 'Jessica'—Rose-pink.
- 'Joya'—Rose-pink.
- 'Jubilee'—A lovely coral pink in early June, low-spreading to 3'.
- 'Louise Dowdle'—Tyrian-pink.
- 'Manhattan'—Bold rose-pink flower, spreading to 4', wider than high, hardy.
- 'Martha Hitchcock'—White flowers with purple edge.
- 'Mary Margaret'—Orange-red.
- 'Masquerade'—White, striped with pink.
- 'Melanie'—Rose pink, hose-in-hose with rose blotch, upright-spreading, 5' high.
- 'Moonstone'—Profusion of cream-yellow flowers, compact mound, semi-dwarf.
- 'Morning Star'—Deep rose.
- 'Nectar'—Fragrant orange-pink.
- 'Niagara'—Exceptionally fine large, frilled, white flowers with a chartreuse blotch, dense growing, 3' high.
- 'Nocturne'—Large, vivid purplish red with darker blotch flowers, early-flowering, broad-spreading, reaching 5'.
- 'Pearl Bradford'—Large, purple-pink flowers, broad-spreading.
- 'Pearl Bradford Sport'—Result of a "witches' broom" that occurred on a plant of 'Pearl Bradford', very petite and dense in foliage and habit, flowers are the same as 'Pearl Bradford'.
- 'Picotee'—White flowers with purple picotee edges, broad-spreading.
- 'Pink Ice'—Large, open-faced, double, light pink flowers with occasional spots and flecks of purple, spreading, 4'.
- 'Pinocchio'—White, striped red.
- 'Pixie'—White flowers with occasional stripes of bright pink, broad-spreading, 5' high.
- 'Polar Sea'—Frilled white flowers with chartreuse blotch, low-spreading, 3' high.
- 'Radiance'—Deep rose-pink.
- 'Refrain'—Rose-pink with white margin, hose-in-hose.
- 'Rosalie'—Bright rose flowers with dark green leaves, late May, spreading to 4'.
- 'Sagittarius'—Fine pink with salmon undertone, low-spreading, 2' high.
- 'Sea Shell'—Deep rose-pink.
- 'Seafoam'—Frilled white flowers with chartreuse yellow throat, broad and low growing, 3' high.
- 'Silverlace'—White with a green blotch, a few purple stripes, broad-spreading, 5' high.
- 'Snowclad'—White with ruffled margins and a chartreuse blotch, low-spreading, 3' high.
- 'Sterling'—Deep rose-pink.
- 'Suwanee'—Rose-pink.
- 'Swansong'—White with yellow blotch, early to mid-June, dwarf, dense and twiggy to 3'.
- 'Swashbuckler'—Red.
- 'Treasure'—White with very light pink edge, single flowers borne on spreading vigorous plants.
- 'Trophy'—Shell pink, very large, heavy informal double.
- 'Ursula'—Pink.

'Vespers'—Frilled white with chartreuse throat, broad-spreading, 5' high.

'Vestal'—Large white flowers with chartreuse blotch, wide-spreading habit, 4' high.

'Violetta'—Light mallow-purple.

'Wavelet'—Bowl-shaped, white flowers, yellow blotch, early June, 4'.

'Wildfire'—Red.

'Zulu'—Very large, purple flowers with a showy blotch of purple dots, mid-May, to 5', colorful fall foliage.

GREENWOOD HYBRIDS (Azaleas)

Concept was compact plants for moist climates. Started in 1960 in Canby, OR. Hardy to Zone 7.

'Maria Elena'—Ideal for temperate, moist climates, double flower is a strong purplish pink and appears in late May, at maturity the plant is broad and rounded, approximately 3' high and wide.

'Nancy'—Double, purplish red flowers are often over 2" across, late-flowering, rounded habit.

'Popcorn'—Sweet-scented white.

'Red Beauty'—Astonishingly large, bright red flowers up to 5" across, long lasting semi-double to double flowers.

'Su-Lin'—Large, deep red flowers which are waxy and beautiful, lovely green foliage all summer, easy to grow.

'Tina'—Rounded, very compact, dwarf plant, strong purplish-pink, hose-in-hose flowers in early April.

HARRIS HYBRIDS (Azaleas)

James Harris, Lawrenceville, GA, produced these large-flowered selections that open later. Some are rebloomers and will be introduced by McCorkle under the Bloom 'n Again™ label. Adapable in Zone 6 to 9.

'Bruce Hancock'—An azaleadendron with 'White Gumpo' and *R. keiskei* as parents, cascading branches, reaches a height of 4', white, 3" flowers bordered in pink, -10°F.

'Fascination'—Flowers red at the outer edges with a pink center, deep green, luscious foliage in summer.

'Joan Garrett'—Salmon-colored, 5" flowers, rounded lobes, 3' spreading plant.

'Miss Susie'—Bright red, hose-in-hose flowers, strong growing, very compact, 3' plant, foliage shiny green in summer and reddish bronze in winter.

'Pink Cascade'—An unusual salmon-pink azalea with long cascading limbs that make this an unusual hanging basket plant, also makes an excellent ground cover when planted on 3' centers.

'Rain Fire'—Large flowers, up to 3" across, May, flowers are red towards orange, single, with broad lobes, plant is mounding and 2' at 10 years, withstands sun.

'Sue Bell'—Two tone flower of light pink with a distinctive darker pink border, plant forms a 3', upright-spreading mound, rounded leaves.

HINES HYBRIDS (Azaleas)

Crosses of Belgian Indica with Southern Indica, evergreen, vigorous, supposedly sun and salt tolerant.

'Cinnamon Sugar'—Single cinnamon-rose.

'Heather Lynn'—Double rose-purple which changes into white blushed lavender-pink with darker edges.

'Ida Marnion'—Double magenta.

'Jessie May'—Single to semi-double, purple with mottled throat and frilled petals.

'Jessie Shirar'—Undulate hose-in-hose, rose-red to pink.

'Lois Hines'—Frilled double, clear orange-desert rose with faint mottling.

'Stella Hines'—Ruffled single, Persian rose flowers.

'Stella Sue'—Ruffled, hose-in-hose, blush rose.

ILAM HYBRIDS (Azaleas)

A strain of deciduous azaleas developed in New Zealand. Rather large flowers completely cover plants in early spring, as hardy as the Exburys, Knaphills and Ghents. Many of the plants produce fragrant flowers, have seen them in Wooster, OH where they were performing well, suspect -10 to -20°F flower bud hardiness.

'Copper Cloud'—Fragrant, deeply frilled orange, heavy flowering, medium habit.

'Ilam Carmen'—Large trusses of warm salmon with a huge marking of gold on the upper petals.

'Ilam Cream'—Huge, fragrant flowers of satin cream, kissed with pink, 5'.

'Ilam Yellow Giant'—Large, over 3", yellow flowers with darker flare.

'Louie Williams'—Trusses of lush pink flowers, two-toned pink, with darker pink buds and a slight yellow marking in the throat.

'Maori'—Vivid orange flowers borne in huge, 10" trusses, plant grows 3 to 4' tall in 10 years.

'Martie'—Frilled dusky red.

'Peach Sunset'—Orange-pink suffused, early, brilliant color.

'Peachy Keen'—Fragrant, with subtle shades of peach-pink, compact semi-dwarf growth habit.

'Persian Melon'—Orange yellow, large trussed like 'Gibraltar', vigorous habit.

- 'Pink Williams'—Clear silvery pink, large slightly fragrant flowers, slow, compact-growing.
- 'Primrose'—Fragrant clear light yellow with golden flare, vigorous but lax grower.
- 'Red Letter'—Brilliant red, vigorous grower.
- 'Red Velvet'—Deep rich red, vigorous-growing, wide upright, red-purple fall foliage.
- 'Rufus'—Deep blood-red, foliage deep bronze.
- 'Spring Salvo'—Dense foliage, deep, full-bodied, reddish orange flowers with a bright orange blotch on the upper petals are 3" diameter in size and bunch together to form 7" diameter trusses.
- 'Supreme'—Deeply fringed, brilliant scarlet flowers, late May.
- 'Yellow Beauty'—Brilliant yellow-orange flowers with a faint blotch and frilly edges, mid to late season.

THE 'IMPERIAL' FAMILY (Monrovia Nursery hybrid introductions)

Splendid varieties in exciting rich colors. Handsome, rich green foliage creates a lush, full plant, a pleasing mounded form. Generously covered with flowers in season and occasionally spotted with color throughout the year.

Imperial Countess—Single, hose-in-hose, deep salmon-pink, petal edges are crinkled, needs partial shade.

Imperial Duchess—Later than above, rose bud-shaped flowers open to bright pink, then become soft pink, form is double, occasionally single, hose-in-hose, needs partial shade.

Imperial Princess—Lovely, long-lasting, large, single, rich pink flowers.

Imperial Queen—Double, pink flowers.

INDICA TYPES: Evergreen (Azaleas)

'Balsaminaeflorum' ('Rosaeflora')—Very low growing, large flowered, double, salmon pink.

'Flame Creeper'—Flowers are orange-red, becoming very popular as a ground cover.

'Jennifer'—Red flowers in spring, shows remontant flowering characteristics, evergreen, 5', a little more cold hardy than Indica types.

'Kate Arendall'—Large heads of white flowers in spring, dark green foliage, evergreen, 5', sister plant to 'Jennifer' and 'Rebekah'.

'Kozan'—Shell pink flowers, late May into June, evergreen, low and mounding.

'Macrantha'—Low, compact, double red, spreading growth habit, 3' high.

'Macrantha Double'—Pretty double orange-pink flowers on compact plants.

'Macrantha Orange'—Bright orange-red flowers produced late on medium-sized plants with bright green foliage.

'Macrantha Pink'—Bright pink flowers produced late on medium size plants with bright green foliage.

'Macrantha Red' ('Osakazuki' or 'Red Macrantha')—Large, red flowers, repeat flowering.

'Macrantha Salmon'—Single, salmon-pink flowers on medium-sized plants.

'Mrs. L.C. Fischer'—Red with darker blotch, single, hose-in-hose.

'Primitive Beauty'—White flowers in spring, similar to "spider" azaleas, evergreen, 5'.

'Rebekah'—Pink flowers in spring, vigorous, evergreen, 5'.

BELGIAN INDICA TYPES

These evergreen azaleas grow best when not exposed to direct sun. Small bushy plants are covered with bright green, lush foliage, an excellent background for spectacular masses of large flowers. Best in Zone 8, 9, 10 to 11, coastal California type climate; primarily greenhouse forcing types. *R. simsii* × *R. indicum*? parentage.

'Ambrosia'—Double, very dark red, prolific flowerer.

'Avenir'—Double, deep salmon-pink, large flowers.

'California Peach'—Large, double salmon-peach coloring, sport of 'California Sunset'.

'California Snow'—Double, pure white, large flowers.

'California Sunset'—Double, variegated white and deep pink, extremely showy.

'Charles Encke'—Variegated pink and white.

'Chimes'—Semi-double, dark red flowers, same as 'Adventsclocke'.

'Dr. Glazer'—Large, double, deep cardinal red.

'Eri'—Large, semi-double, mottled pink and white.

'Freckles'—Semi-double, hose-in-hose, delicate white, red mottling, profuse.

'Jezebel'—Semi-double, deep cardinal red, hose-in-hose.

'Kathryn Aileen'—Huge, single red.

'Leuchtfeuer'—Single to semi-double, vibrant red.

'Marie-Louise'—Single, white sometimes splashed with pink, sport of 'Charles Encke'.

'Memoire John Hearrens'—Double, white edged with dark cerise.

'Mme. Alfred Sander'—Double, cherry red.

'Mme. Petrick'—Double, red.

'Orange Chimes'—Semi-double, bright orange.

- 'Orange Sanders'—Double, orange sport of 'Fred Sanders'.
- 'Paul Schaeme'—Double, light orange.
- 'Professor Wolters'—Single, variegated rose-red and white, ruffled edge.
- 'Red Poppy'—Very large, single to semi-double, bright deep red.
- 'Rose Glow'—Large, single, rose-red.
- 'Salmon Solomon'—Salmon flowers.
- 'Satellite'—Frilly, double to semi-double, 4", white with large rays and stripes of a vivid deep pink flowers, plant is vigorous, upright-spreading.
- 'Tickled Pink'—Single to hose-in-hose, rose-pink, edged in white.
- 'Triumph'—Double frilled red.

SOUTHERN INDICA TYPES

- Best azaleas for high light areas, in coastal plain of the Southeast, vigorous, upright growers to 5 to 10' high, profuse spring flowers, hardy to 20°F. Listed as being developed around 1870.
- 'Albert-Elizabeth'—White with orange-red edges.
 - 'Brilliant'—Single, watermelon red.
 - Crimson Series—In mid-June 2004, I witnessed one of the series with bronze-purple-green foliage and compact habit; Todd Lasseigne, then curator, Raulston Arboretum, mentioned they were sports of 'Formosa' with names: 'Crimson Majesty' (PP 14,362), 'Crimson Princess' (PP 14,360) and 'Crimson Queen' (PP 14,343); I have not observed them in flower; habit in containers was dense; originally from Louisiana.
 - 'Daphne Salmon'—Salmon flowers.
 - 'Dixie Beauty' ('Formosa Red')—A deep red sport of 'Formosa'.
 - 'Duc de Rohan'—Single, salmon-pink.
 - 'Elegans'—Light pink.
 - 'Fielders White'—Large, single, frosty white, 2 3/4" diameter.
 - 'Fisher Pink'—Pink flowers.
 - 'Formosa'—Magenta with deep blotch, single, 3" diameter flowers, large upright habit, more cold hardy.
 - 'G.G. Gerbing'—Pure white, single, 3" diameter, sport of 'George L. Taber', more cold hardy than the typical Southern Indica, flowered heavily after 13.8°F in 2008–2009 winter.
 - 'George L. Taber'—Very large, single, light orchid-pink, variegated, 3" diameter, more cold hardy than most, abundant flowers after 13.8°F.
 - 'Gulf Pride'—Light lavender, tall upright, mid-season.
 - 'Hexe de Saffelaere'—Red, hose-in-hose.
 - 'Iveryana'—Single, white with orchid streaks, mid-season.
 - 'Judge Solomon'—Pink, single, 3" diameter flowers.
 - 'Lady Formosa'—Large, single, violet-red, weeping habit.
 - 'Lawsal'—Salmon-pink, same as 'Daphne Salmon'.
 - 'Little Girl'—Light pink, with silver tips to petals, double.
 - 'Little John'—Large, single, burgundy red flowers, symmetrical form accented by eye-catching reddish purple foliage.
 - 'Moss Point Red'—Large red flowers, broad-spreading habit, same as 'Triumphe de Lederberg'.
 - 'New White'—White.
 - 'Orange Pride'—Bright orange, single, listed also as 'Orange Pride of Dorking'.
 - 'Phoenicia'—Single, lavender-purple.
 - 'Pink Formosa'—A pink-flowered sport of 'Formosa'.
 - 'Pink Lace'—Petite, single, very compact, light rose-pink.
 - 'Plum Crazy'—Large, deep mauve, single flowers have white and lilac-pink marbling with a blush of pale mauve overtone.
 - 'President Clay'—Orange-red, single, 2 1/4 to 3" diameter.
 - 'Pride of Dorking'—Single, brilliant carmine-red.
 - 'Pride of Mobile'—Deep rose-pink, single, 2 1/2" diameter.
 - 'Prince of Orange'—Heavy-textured, orange flowers.
 - 'Red Formosa'—Deep violet-red flowers, large dark green foliage.
 - 'Redwing'—Red, hose-in-hose, 3 to 4" diameter flowers.
 - 'Reverie'—Single, violet-pink, mid to late season.
 - 'Rosa Belton'—Cream with bright lavender edges, large, single, profuse.
 - 'Rosea'—Semi-double, rose-red flowers open from rose-like buds.
 - 'Southern Charm'—Large, single, deep rose, a sport of 'Formosa'.
 - 'Star Trek'—White, with very pale green throat, formal double.
 - 'White April'—Large, single, pure white.
 - 'White Grandeur'—Snow white, large, double flowers.

KURUME HYBRIDS (Azaleas)

From Japan, long, complex ancestry including *R. kiusianum*, *R. kaempferi* and *R. sataense* as well as the Obtusum Group. Over 700 cultivars. Zone (6)7 to 9. Flower late March–early April, Athens.

'Amoena'—Flowers rich magenta, hose-in-hose, old cultivar, hardier than most, see under *R. obtusum*.

'Amoena Coccinea'—Small, hose-in-hose, red flowers, densely twiggy, compact and low-growing, –8°F.

'Appleblossom'—Light pink.

'Better Times'—Pink, hose-in-hose.

'Bridesmaid'—Salmon.

'Christmas Cheer'—Red, small, hose-in-hose flowers produced on dwarf, medium-spreading plants.

'Coral Bells'—Coral pink, small, 1 1/2" diameter, hose-in-hose flowers produced on dwarf, low-spreading plants, 3' by 3 to 4', one of the most commonly available.

'Delicatissima'—White flowers are flushed a delicate pink, profuse, upright-spreading.

'Eileen'—Blush pink, semi-double to hose-in-hose.

'Eureka'—Pink.

'Flame'—Orange-red.

'Hahn's Red'—Low growing, bright red flowers.

'Heather'—Attractive rose-lavender.

'Hershey's Red'—Early, large, 2" diameter, bright red, hardier than most, probably to –10°F, common in trade.

'Hexe Supreme'—Crimson, medium, hose-in-hose.

'Hino Orange Sport'—Sport from 'Hinodegiri', salmon orange flowers in profusion mid-season.

'Hino-red' ('Hino-crimson')—Brilliant non-fading crimson flower, single, one of the hardiest, low growing compact with small, deep glossy green leaves turning bronze in winter; flowers opening mid March at University Botanical Garden.

'Hinodegiri'—Vivid red, 1 1/2" diameter flowers, dark green summer foliage turns wine-red in fall and winter, 3' by 3 to 4', flower buds test hardy to –8°F; flowers starting to open mid March at University Botanical Garden.

'Hinomayo'—Soft pink flowers in profusion, wide upright, slow-growing.

'Hinoscarlet'—Hose-in-hose, red flowers, wide upright plant, bronze-red autumn foliage.

'Ho-Oden'—Light lilac pink flowers with white edges and violet red blotch measure 2 1/2", low-spreading plant.

'Kermesina'—Fuchsia pink flowers, vigorous, small growing plant, small leaves.

'King's Luminous Pink'—Brilliant contrast of luminous purplish pink margins surrounding a white throat and starry white rays, hardy, 4 to 5' in 10 years.

'Konohana'—Deep coral pink flowers marked with a purple blotch.

'Koromo Shikibu'—Lavender flowers have very narrow separate petals and measure 2 1/2", upright-spreading plant.

'Massasoit'—Single red flowers on dwarf, dense plants.

'Mauve Beauty'—Mauve, hose-in-hose.

'Mildred Mae'—Pale lavender, large, single.

'Mother's Day'—Large, red flowers, wide-growing.

'Peach Blossom'—Pale salmon-pink.

'Pink Pearl'—Pink, medium-sized, hose-in-hose flowers on dwarf, upright plants.

'Red Bordeaux'—Red-orange.

'Ruth May'—Single, bi-color flower in pink and white, medium grower.

'Salmon Beauty'—Salmon-pink, hose-in-hose.

'Sherwood Cerise'—Single, cerise.

'Sherwood Orange'—Early, vibrant orange flowers, compact growth habit, originated at Sherwood Nursery, Oregon.

'Sherwood Orchid'—Reddish violet with a darker blotch, single.

'Sherwood Pink'—Single, pink.

'Sherwood Red'—Orange-red, medium-sized, single flowers on dwarf, low plants.

'Snow'—Pure white, hose-in-hose, vigorous grower, common.

'Snowball'—White, hose-in-hose flowers, glossy medium green leaves, broad-spreading plant.

'Sweetbriar'—Hose-in-hose, pale pink flowers flushed red with a darker blotch, wide, upright.

'Tradition'—Clear light pink, double.

'Vesuvius'—Salmon-red.

'Ward's Ruby'—Brilliant ruby red, single.

'Yoro'—Very long stamens peering out from the clear white flowers.

LINWOOD HYBRIDS (Azaleas)

- 'Hardy Gardenia'—Abundant, white flowers resemble *Gardenia*, especially when just unfurling, dense shrub, flowers in mid-spring, handsome green foliage in winter, 2'.
- 'Janet Rhea'—Semi-double, hose-in-hose flower in variegated colors of salmon, pink and rose with white edges, dwarf spreading plant.
- 'Linwood Blush'—Salmon-pink, semi-double.
- 'Linwood Lustre'—White, semi-double.
- 'Linwood Pink Giant'—Pink, hose-in-hose.
- 'Linwood White'—Double, hose-in-hose, white flowers with no stamens, tall, mid-May.
- 'Little Gardenia'—"Witches' broom" of 'Hardy Gardenia', white, double flowers, tight growing dwarf plant, heart-shaped dark green leaves, 1/4 to 1/3 normal size, ultimate height is probably 2'.
- 'Opal'—Hardy, low-growing plant, bright lavender pink, double flowers spotted with red in the throat, often will flower again in the fall.
- 'Salmon Pincushion'—Luscious double, salmon pink.
- 'Slim Jim'—Double, pink, an upright grower.

LOBLOLLY BAY HYBRIDS (Azaleas)

Selected from seedlings of Glenn Dale azaleas. Zone 6 to 9.

- 'White Frills'—White with yellow-green blotch, hose-in-hose.

MAYO HYBRIDS (Azaleas)

- 'Princess Augusta'—A large grower with light pink hose-in-hose, 2 1/2" diameter flowers.

MISCELLANEOUS AZALEAS

No clear cut home so they are included here in alphabetical order.

- 'A Little Bit More'—Rounded, pure white petals with an occasional fleck of pink, a low spreader, June into July.
- 'Abigail Adams'—Evergreen, large, bright pink flowers, wide-spreading mound-shaped, vigorous, named in 1994 for the Abigail Adams Historical Society of Weymouth, MA.
- 'Alice de Steurs'—Flower changes in shading from yellow to salmon, bearing a strong deep orange blotch.
- 'Amelia Becales'—A more compact version of the lovely 'Martha Hitchcock' with white flowers bordered in rosy lavender.
- 'Ami Gasa'—Vivid red with wide overlapping lobes, large flowers
- 'Anna Kehr'—Evergreen shrub, 4', strong purplish-pink double, 2" diameter flowers.
- 'Anna's Smile'—Lightly sweet-scented flowers turn peach-pink as they mature, rounded shiny green foliage, wide and upright-growing hybrid of the Ghent and sweet azaleas.
- 'Atrosanguineum'—Low to medium in height, with growth habit like 'Ward's Ruby' or 'Hino Crimson', excellent red flowers.
- 'Baby It's You'—Bright coral pink, with a deeper coral rose flare on the upper 3 petals, narrow, dark green pointed leaves, a low spreader, June.
- 'Baby's Blush'—White, star-shaped flowers with a light rose speckling in the blotch, slightly whiter with a less prominent blotch than 'Sweet Maiden's Blush', mid-May.
- 'Baltic Amber'—Rounded heads of golden yellow flowers in early June, blue-green leaves appear dusted with silver, wide and upright with stout branches.
- 'Barbara'—Single, rich pink, a selection of *R. tasaense*, evergreen.
- 'Brienne'—Sport of 'Girard Rose', similar to 'Silver Sword', hardier, with a thinner, longer dark green leaf with a whole margin, leaf is tinged pink during winter.
- 'Burning Bush'—Late flowering, red as blazes from its parents 'Satan' × red *R. calendulaceum*, large growing plant hybridized by Olin Holsomback, Georgia.
- 'Camisole Fuchsia'—Rich fuchsia purple, hose-in-hose with a lovely second swirl of petals underneath the first, early to mid-May, 3' by 3' in 10 years.
- 'Camisole Rose'—Hose-in-hose rose red, early May, 3' by 3' in 10 years.
- 'Canby'—Bi-color with yellow-orange flowers.
- 'Cape Cod'—Low-growing, spreading form, covered with pure white hose-in-hose flowers.
- 'Cardinal'—Scarlet red sport of 'Mother's Day', burgundy fall foliage, compact, early May.
- 'Carlson's Dusty Pink'—Soft subdued, or dusted, light pink flowers, mid-May.
- 'Carlson's Itsy Bitsy'—Glowing coral orange hose-in-hose flowers, glossy foliage, 18" tall by 2' wide in 10 years, mid-May.
- 'Carlson's Pink Postscript'—Specially selected to add pink shades to the palette of orange, red, and white azalea species that flowers late in the season.
- 'Carlson's Postscript'—Mixed shades of pink, yellow, cream, and coral that haven't yet been tagged for color.

- 'Cherry Delight'—Compact plant reaches 2 to 3' in 5 years, strong cherry-red, single flowers in abundance.
- 'Cherry Drop'—Flowers bright red, tiny leaves are dark green and deciduous, buds in early spring are bright red, plant is 3" tall and 8" across in 8 years.
- 'Chippewa'—Filly, 2 1/2" diameter flowers of lilac-rose have a deeper blotch, flowers late, dense, upright plant, medium height.
- 'Choice Cream'—Early flowering, fragrant, clear lemon yellow, yellow flare, touch of pink in the tube, 5' high.
- 'Come To Baby Do'—Coral pink with a subtle deeper flare, a low spreader, June.
- 'Cookie'—Large flowers, rose spotted with maroon, wonderful fragrance, large leaves, upright plant, to 4'.
- 'Corneille'—Soft, double, pink flowers late mid-season.
- 'Daviesii'—Fragrant pale cream flower with a yellow flare in late May.
- 'Debbie'—Small dark forest green leaves, deep, bright, blood red flowers, 2' high.
- 'Donald Waldman'—Large, showy, semi-double flowers, red center surrounded by a pink flare on each petal and a contrasting white margin, low and compact plant.
- 'Double Pink'—Double flowering pink, outer petals of the buds are a dark pink which open to reveal the pale pink petals of the inner flower, and each is finally topped with a flare of yellow.
- Double Pink Hybrids—Fully double, ruffled, clear pink flowers, late April and early May, small, dark green summer foliage, becomes coppery bronze in winter, slow-growing, wide and upright, ten-year-old plant is 4' tall and 2' wide, mature plant will be 6' or more tall.
- Double White Hybrids—Multi-petaled, white flowers in late April and early May, compact, upright and wide-growing, small dark green leaves, interior foliage turns yellow before dropping in fall.
- 'Early Erroll'—Star-shaped, white flowers with dark tipped white stamens, a few lavender specks in the throat, carries in the garden as white, early to mid-May.
- 'Early On'—Bright glowing coral pink, one of the earliest evergreen azaleas, 5' by 6' in 20 years, dark burgundy fall color.
- 'Eleanor Allan'—Masses of soft pink flowers with a slightly deeper pink throat, low-spreading, heavy flowering, mid-May.
- 'Face 'Em Down Pink'—Selected soft pink forms that have not yet been named.
- 'Face 'Em Down White'—Selected white forms that have not yet been named.
- 'Fairfax'—Large, heavy-textured flowers marbled pink and white, dense, low growth habit.
- 'Firecracker'—Vivid red flecks burst and sparkle from the pure white flowers with distinctive rounded lobes late in the season, low-spreading mound.
- 'Firestar'—Clear scarlet red with pointed petals, hardy, upright with bright orange-red and orange-yellow fall foliage, mid-May.
- 'Florence Waldman'—Large, semi-double, hose-in-hose, white flowers are sanded and spotted with red flecks, upright-spreading.
- 'Galle's Choice'—Fragrant, light yellow flowers with white throats and light pink tips on wavy lobes, mid-season.
- 'Gordon'—Single, medium red flowers, hardy, early May.
- 'Great Expectations'—Double, orange-red flowers in spring, compact to 4' high.
- 'Green Glow'—Each ivory petal is suffused with an incandescent green glow, intensified by a yellow green eye, long lasting flowers, double hose-in-hose, low plant with rounded leaves.
- 'Hamlet'—Salmon-orange flowers are blotched on the upper petal with a huge, dark, red-orange flare.
- 'Happy Days'—Deep violet-purple, double flowers, heavy flowering in spring.
- 'Hill's Bright Red'—Vibrant red flowers on red stems, dark green leaves with deeper veining, 3' high.
- 'I'll Be Damned'—Broad, mounded, dense plant, huge (to 5 1/2" diameter) petaloid and deeply ruffled pink and white flowers.
- 'Il Taso'—Rose-red flower has a strong hint of salmon throughout, hose-in-hose flowers open a warm light salmon and darken to nearly a salmon-red.
- 'In A Mist'—Fragrant, star-shaped, white flowers with a faint watercolor wash of pale lavender pink, mid-May.
- 'In The Pink'—A hardier star-shaped, white flower with a light lavender flush, speckled red-purple blotch, mid-May.
- 'Ivan D. Wood'—Vigorous plant, large trusses of pinkish-cream blending toward the center into deep glowing yellow, large foliage is attractive, good grower, 3' high.
- 'Jack A. Sand'—Beautiful double flower which is bright pinkish red on the edges melting into a lighter yellowish-pink in the center, orange-yellow blotch on the upper petal, flowers are frilled and fragrant.
- 'Jane Elise'—Dark pink flowers in June, mounded plant.
- 'Janice Lynn'—Large, pink, semi-double, hose-in-hose flowers have a red flare and flecks of rosy red spread over its many petals, low-spreading habit.
- 'John Eichelser'—Large, ball-like trusses of candy pink flowers in spring.

- 'Joseph's Coat'—Flowers open yellow, turn orange and then red, cross of *R. bakeri* × *R. viscosum*, floriferous.
- 'Judie's Pink Angel'—Large partially petaloid flowers in rich shades of pink with a deeper pink flare, late May.
- 'Kagura'—Hose-in-hose, rose pink flower has blended white throat and dark blotch, stamens are longer than the petals, early season flowering, medium size.
- 'Kazan'—Showy orange-red flowers in June, small pointed shiny dark green leaves, a unique dwarf.
- 'Kennedy'—Superb red-orange flower highlighted with a slight yellow-orange blotch on the upper petal, frilled on the edge.
- 'Kennell's Gold'—Apricot buds open to large fragrant golden yellow flowers with a touch of red in large, ball-shaped trusses, upright-spreading habit, good fall color.
- 'Keowee Sunset'—Medium pink flowers with a yellow-orange flare on the upper petal, red pistils and filaments, flowers appear mid-season, upright-spreading plant, *R. calendulaceum* and *R. periclymenoides*.
- 'Konningen Emma'—Light orange yellow when young to strong orange yellow and finally to a suffused yellowish pink with a strong orange blotch, 2 1/2" flowers, tall upright plant, mid to late season.
- 'Koromo Shikabu'—Strap-like petals are purplish pink with darker tips, hairy leaves, spreading, late May.
- 'Lady Jayne'—Vivid yellow suffused with reddish-orange and marked by an orange yellow flare, large, fragrant wavy textured flower, low growing, reaching about 3'.
- 'Lemonora'—Flowers yellow with a tinge of pink, tall and upright to a height of 8' by 6'.
- 'Li'l Darlin'—Very large, lavender pink flowers, mid to late June, low-spreading.
- 'Little Frosted Orange'—White flowers with orange frosted border, compact, spreading mound.
- 'Little Gem'—Blood red flowers, prostrate plant, glossy, deep green leaves.
- 'Lorna X'—Late, hot pink with double flowers, more compact and lower growing than Gable's 'Lorna'.
- 'Luminosity'—Large, luminous clear rose pink, deeper speckling on the upper petal, mid-May.
- 'Mme. Butterfly'—Beautiful white flushed lavender, single flowers, low-spreading, mid to late May, especially hardy.
- 'Majesty'—Dark wine-red flowers in May, long, glossy, rounded, deep green, evergreen foliage turns burgundy in winter and is well-retained, low and compact-growing, mature plant is wider than high.
- 'Margaret Douglas'—Large, red-margined flowers have pink centers, low-spreading habit.
- 'Mary Lou Kehr'—Lovely, double pink camellia type flowers with the added bonus of fragrance, good form to 5', and a lovely tribute to Dr. Kehr's wife.
- 'Matthew's Memory'—Bright golden yellow flowers in a petaloid double, long-lasting form, plant habit is upright, vigorous growth.
- 'Melford Lemon'—Glowing yellow flowers have an apricot flare.
- 'Mike Bullard'—Striking hot pink, early flowering, tall.
- 'Mildred'—Orchid purple, single, flowers early season.
- 'Miss Susie'—Strong hose-in-hose red flowers on compact, dark green plants, mid-season.
- 'Missy'—White flushed pink with a distinctly deeper rose blotch, colorful.
- 'M.L. Webb'—Rounded trusses of salmon pink flowers, bright green wavy leaves turning to a brilliant red fall foliage.
- 'Moonlight Rose'—Luscious, wavy, pale pink flowers enhanced with a bright yellow flare, upright growing.
- 'Mt. Ranier'—Large trusses of white flowers accented by a dark yellow flare, light fragrance, floriferous, upright-spreading plant.
- 'Nancy Plent'—Rich pink, large flowers, medium height, as wide as tall, mid-May.
- 'Nanticoke'—Double white flowers with many varied markings of pink to light purple, low cascading branches.
- 'Nico Red'—Sometimes called simply 'Nico', deep red flowers mid-season, compact plant.
- 'Nudiflora Pink'—Subtle old-fashioned pink with an antiqued look, mid-May, very hardy.
- 'Olympic Sunrise'—Peachy pink, hose-in-hose flowers with an orange throat, upright-spreading habit.
- 'Orange Splendor'—Funnel-shaped, frilly-edged, vivid red-orange flowers, mid to late May, upright-spreading, hardy.
- 'Otome-No-Mai'—Grows 2 to 4' high spreading to 4', violet flowers in spring repeating sporadically through the growing season.
- 'Peggy Ann'—Charming white hose-in-hose flowers edged in raspberry pink, compact, early May.
- 'Penna'—Deep rosy pink double flowers, upright-spreading to 5 to 6'.
- 'Pennsylvania'—Deciduous, delicate-pink flowers the third week of July, each flower has an orange eye and remains colorful with a touch of sweet, fruity fragrance into early August, wide-growing, slow and upright, small, rounded, apple-green foliage turns a distinctive coppery yellow before dropping in autumn.
- 'Pink Clusters'—Densely clustered, ruffled, bright pink flowers in mid-May, each flower is heavy-textured and has an orange coloration on one petal, low-growing, dwarf and spreading, a 10-year-old plant is

- 18" by 3', small, dark green leaves are wide, oval-shaped, foliage retained all winter is bronze-red until warm weather returns.
- 'Pin Cushion'—Lavender hose-in-hose flowers, mature plant is a dense, low-spreading mass.
- 'Pink Patootie'—Slightly rounded flowers in a delightful shade of antique pink, warm faint golden speckling in the throat, mid-May.
- 'Pink Pockets'—Dusty pink with tight fitting hose-in-hose flowers in early May, low growing.
- 'Pink Radiance'—Radiant pink, long lasting flowers with a white stripe down the reverse center of each lobe, vigorous upright plant, rich red fall color.
- 'Pocahontas'—Dark red flowers, evergreen, small foliage.
- 'Polypetalum'—Brilliant orange flowers, corolla is not fused, instead the petals are mere strips of scarlet orange, hardy, flowers late.
- 'Pride of Lindenhurst'—Large, white hose-in-hose flowers are bordered in pink, low and compact plant.
- 'Prominent'—Dusty orange brick-red with a dark speckling on the upper petal.
- 'Pure Perfection'—Clear white hose-in-hose flowers with wavy petals have a touch of light green in the throat, low mounded habit.
- 'Purple Pinwheel'—Low, almost prostrate plant, rich purple flowers late in the season with each individual strap-like petal whirling about the center, hairy attractive leaves, vigorous plant.
- 'Quiet Thoughts'—Fragrant, yellow-orange flowers in late May, deciduous.
- 'Radiant'—Deep reddish-orange to almost brick red flowers.
- 'Red Fuzzy'—Evergreen ground cover, 1' by 5', red flowers in spring.
- 'Red Planet'—Bright medium red flowers, dark green foliage with a bronzy tint, vigorous grower with a bushy plant habit.
- 'Rising Star'—Huge orange flare set on a background of white, edged with a tinge of salmon.
- 'Rosalie Nachman'—Large, light shrimp pink flowers with a vivid pink blotch, low-spreading plant.
- 'Rosy Ruffles'—Full truss of frilly rose pink flowers, upright plant habit reaching about 6' by 4' in sixteen years.
- 'St. James'—Orange-red with red blotch and white center, large, tall, spreading plant, mid-season.
- 'Salmon Queen'—Salmon bud opening to warm peach, accented by a golden flare, as the flower ages, colors become muted, apricot-goldens to paler peach-yellows.
- 'Sandy'—Violet-scented, apricot-pink flowers with a yellow flare on the top petal, late June, wide mound form, glossy, rounded, dark green leaves with blue-green undersides.
- 'Saturnus'—Large reddish orange flowers.
- 'Secret Wish'—Frosty white petals on puffy, double camellia-like flowers, vigorous, upright plant reaching 5'.
- 'Short Sheet'—Clear white with a subtle hint of chartreuse deep in the throat, late June into July, spreading to 24" in 10 years but less than a foot high.
- 'Silver Slipper'—Shimmering light pink to white flower with an orange patch, late May, upright plant.
- 'Siskin'—Bright yellow flowers, late May and early June, robust, wide and upright-growing plant with stout branches, prominent winter buds, dark green foliage, mildew-resistant.
- 'Snowball'—A hardy white from Ohio, 3', mid-May.
- 'Snowbird'—Powerfully fragrant white flowers appear in spring with or before the first leaves, compact habit; see comments under *R. atlanticum*.
- 'Soft Echo'—Double pink flowers, darker on the margins and lighter in the center, forming a ball shaped truss, 4 to 5' plant is upright-spreading.
- 'Soft Shimmer'—Hose-in-hose flower that opens from soft pink buds to a white flower, touched on the outer edges with pink, while the inner petals of the flower are pure white, gradually the whole flower becomes pinker, until it is a soft pink throughout.
- 'Sport of Easter Parade'—Double, rose red with creamy white blotches.
- 'Stadtman'—Gigantic, fully double, creamy yellow flowers have a gold flare and a touch of red or yellow coloring on the petal tips, colorful fall foliage shadings of yellow or red.
- 'Starry Eye'—Star-shaped, white flowers kissed with a distinctive pink tip at the end of each petal.
- 'Stolen Kiss'—Medium pink, semi-double flowers enhanced by a golden flare, long flowering period, burgundy fall color, 6', upright-growing plant.
- 'Summer Gold'—Slightly fragrant, yellow flowers have a darker yellow flare, large, dark green foliage, upright growing and vigorous.
- 'Summer Lyric'—Soft pink, star-shaped flowers glow with a yellow throat in June and July in ball shaped trusses, bright green leaves, vigorous growing larger plant.
- 'Summer Rose'—Dark, rose-pink flowers in June, long leaves on reddish stems, wide growing.
- 'Supersuds'—Large star-shaped white flowers with soft green-gold speckled blotch, mid-May.
- 'Susan Oliver'—A prostrate low spreader with double, lavender-pink flowers in late June, exceptional.
- 'Sweet Maiden's Blush'—White star-shaped flowers with rose purple speckling in the blotch, lavender and white stamens, mid-May.

- 'Sweet September'—Clear pink flowers and red stamens in September, upright habit, *R. prunifolium* × *R. arborescens* hybrid.
- 'Texas Pink'—Dark pink flowers in May, small, rounded, dark green foliage becomes reddish orange in autumn and is partially retained, dwarf-growing and mound-shaped, growing less than two inches a year.
- 'Thomas Jefferson'—Large, fragrant flowers with ruffled petals form full trusses of a soft salmon tone, symmetrical 4' mound in six years.
- 'Totally Awesome'—Large-flowered, brilliant yellow combined with light yellow, vivid reddish orange shading to the edges of the flower, stamens are often petal-like.
- 'Toy'—Olin Holsomback from Chickamauga, GA, hybridized *R. arborescens* and *R. viscosum*, heat and cold tolerant, late flowering, apple blossom pink.
- 'Vida Brown'—Ruffled deep rose pink hose-in-hose flowers, compact and low, neat, tight foliage, late May.
- 'Vinecourt Duke'—Double, dark pink flowers with a heavy substance, soft fragrance, clusters of ball-shaped trusses have as many as 50 to 55 flowers, plant is upright and floriferous.
- 'Vinecourt Troubadour'—Strong red, softly fragrant, double flowers appear in domed trusses in mid-May, free-flowering, dense, upright habit.
- 'Vineland Dream'—Bright pink flowers with a slight orange flare appear in full trusses of 20 to 22 flowers, very floriferous, dense upright habit.
- 'Virginia Knight'—Large, hose-in-hose, pink flowers with light red blotch.
- 'Viscosepala'—Extremely fragrant creamy white flowers, late May into early June, 5', upright-growing, red-orange fall foliage.
- 'Vyking'—Dark rose red flowers in late May, glossy, rounded leaves turn purple-red in fall, some remaining on branches in winter, wide-spreading and compact-growing.
- 'Wachet'—Rich pink, large flat single flower, ruffled margins, mounded, broad and dwarf.
- 'Washington State Centennial'—Flowers open light orange-yellow and pale to white, with a blotch of vivid glowing yellow on the upper petal, petals are frilled and the flowers are fragrant, leaves are very shiny and resistant to mildew.
- 'Weird-O'—White, strap-like petals that are twisted or turned so that no two flowers are the same, resembles a Witchhazel flower, vigorous growing.
- 'White Rosebud'—White, double flowers with green-tinged center; 3' by 3'; from the late August Kehr.
- 'Whitestone'—Double white flowers, plant is upright in habit.
- 'Whitney's White'—Scented, single white flowers on a upright growing plant, hardy, late May.
- 'Williamsburg'—Hose-in-hose flowers of white marked with strawberry pink and occasional solid pink flowers, broad, glossy green mound, 3'.
- 'Wombat'—Salmon-pink flowers, low-spreading, leaves having brown hairs over deep green base color.
- 'Yachiyo Red'—Not red, but white with pastel pink frosting, variable rose pink markings, tiny dark green leaves, low and compact, June.

NUCCIO HYBRIDS (Azaleas)

Nuccio Nursery, California, developed these evergreen azaleas that date from mid-1930s.

- 'Garden Party'—Pink with peach flare.
- 'Nuccio's Carnival'—Large, single to semi-double, rose-red flowers, vigorous, 3' high and wide, long flowering season.
- 'Nuccio's Happy Days'—Deep violet-purple double flower, heavy spring flowers.
- 'Nuccio's Pink Champagne'—Light pink, double, hose-in-hose.
- 'Nuccio's Wild Cherry'—Large single flowers, round petals of cherry red, rapid upright grower, height 3 to 5'.

PENNINGTON HYBRIDS (Azaleas)

The late Ralph Pennington of Covington, GA, produced these outstanding plants. A collection was housed at the University's Botanical Garden.

- 'Beth Bullard'—Spreading plant with dark green foliage, 4" diameter reddish pink flowers, an excellent low-growing azalea, 2 1/2' tall with a spread of 4 to 5'.
- 'KJP'—Flowers light pink with dark pink stripes, 4" diameter, foliage is like the Southern Indica, plants grow 5 to 6' high.
- 'Mrs. Anne G. Pennington'—A very late, variable pink and white flower with blotches on a low growing plant, a late edition of 'KJP'.
- 'Mrs. R.W. Pennington'—A bright red flower on a low, bushy plant.
- 'Pennington Purple'—An early, fragrant, lavender flower on a well-formed plant.
- 'Pennington Red'—A striking, early, all-red flower on a medium shrub.
- 'Pennington White'—An early, 2" diameter, frilled, white flower that is the best of the early whites.

PERICAT HYBRIDS (Azaleas)

The Pericat Hybrids are similar to Kurume Hybrids, with larger flowers. Utilized primarily for greenhouse forcing, they do display Zone 7 to 9 adaptability.

'China Seas'—Pink.

'Dawn'—Phlox-pink.

'Distinction'—Salmon-pink, semi-double.

'Flanders Field'—Red.

'Fortune'—Red.

'Hampton Beauty'—Rose-pink.

'Hiawatha'—Hose-in-hose, red.

'Miss Augusta'—Hose-in-hose, 2" diameter, red flower, late mid-season, grows 4 to 6' high, introduced by the late C.S. McCorkle.

'Pericat Pink'—Pink.

'Pericat Salmon'—Salmon.

'Pericat White'—White.

'Pinocchio'—Rose.

'Sensation'—Violet-red.

'Splendor'—Phlox-pink.

'Sweetheart Supreme'—Small, semi-double buds resemble delicate rosebuds, blush pink at maturity.

'Twenty Grand'—Violet-red, semi-double.

POLLY HILL'S NORTH TISBURY HYBRIDS (Azaleas)

Beginning in 1957, the late Mrs. Polly Hill, Martha's Vineyard, MA, tested and selected Japanese azaleas that she grew from seed. Her objective was to produce prostrate, hardy, evergreen forms for ground cover use. Low growing azaleas with trailing branches that cascade over rocks or walls make suitable ground covers. Most are hybrids of *R. nakaharae*, a prostrate evergreen species, that may reach 2 to 5" in height in 10 years. As hybrids they are hardier than the species, benefiting from available snow cover. Flower in May–June. Witnessed several at The Polly Hill Arboretum. Beautiful plants but seldom available in modern day commerce. Hardy to –5°F, more in specific cases.

'Alex'—A dwarf sport of 'Alexander', petite, prostrate and red.

'Alexander'—A low-growing spreading azalea eventually reaching 18" high, flowers are salmon-red and open in late May and early June, excellent ground cover plant, cold hardy between 0 and –10°F.

'Andante'—A small to medium compact plant with salmon-pink flowers.

'Bartlett'—Covered with flowers most of June, the lightly ruffled flowers are medium pink, low, dwarf habit, –10°F.

'Cornia Borden'—Pale pink flowers with a slightly darker blotch, slow-growing, upright-spreading habit.

'Flat Out'—Vigorous late flowerer that blankets the ground with white, a ground hugging spreader, a perfect complement to the North Tisbury Azaleas.

'Fuzzy'—Brilliant orange flowers, prominent pubescence on stems and leaves.

'Gabrielle Hill'—Light pink with a rosy crimson blotch, plant habit is airy, irregular and not too dense, original plant is 15" tall and 5' across.

'Hill's Single Red'—Salmon-red flowers on a compact, spreading plant.

'Hotline'—Large ruffled flowers, hot purple-red, 1 1/2' by 4' after 16 years.

'Jeff Hill'—Deep pink flowers, plant is rounded, semi-dwarf and branching well, 17" tall by 26" wide in 13 years.

'Joseph Hill'—Bright red flowers, 12" tall by 42" wide in 13 years.

'Lady Locks'—Fragrant, lavender frilled flowers with large sepals.

'Late Love' ('Summertime')—Bright pink flowers, the latest of the North Tisbury Hybrids.

'Libby'—A gorgeous fresh cool pink.

'Marilee'—Rose-red flowers, smoky purple-green leaves are retained well, 16" tall by 50" wide in 12 years.

'Michael Hill'—Late soft pink frilled flowers with dark throat, very dwarf and spreading, an excellent ground cover, 17" tall by 45" wide in 13 years.

'Midori'—Large, snowy white, wavy flowers, low-spreading, compact habit.

'Mount Seven Star'—A vivid red with wavy lobes on a low, dense plant.

'Mrs. Hill's Flaming Mamie'—Red flowers.

'Pink Pancake'—Large, bright pink, wavy flowers on one of the fastest growing of all the North Tisbury Hybrids.

'Red Fountain'—Flowers are a strong red on branches that reach up at first, then arch down in a conspicuous fountain-like curve.

'Susannah Hill'—Deep red flowers with petaloid stamens, plant forms a vigorous low mound, 15" tall by 52" wide in 12 years.

'Trill'—Large, ruffled, medium red flowers, 14" by 28" in 12 years.

- 'Wintergreen'—Deep pink to light red flowers in late June, forms a circular mound 15" by 39" wide in 12 years.
- 'Wintergreen' ("witches' broom")—A smaller leaved, more compact sport of 'Wintergreen', deep pink flowers in late June.
- 'Yuka'—Another of Polly Hill's best 'Gumpo' seedlings, large flowers, most are pure white, some are striped with soft pink, others are nearly solid pink, low growing.
- 'Yukette'—A dwarf sport of 'Yuka', smaller and more consistently white, late May into June.

ROBIN HILL HYBRIDS (Azaleas)

After some 50 years of hybridizing and selecting, Robert Gartrell succeeded in taking the flower characteristics of the Japanese Satsuki azaleas and producing a group of evergreens that are as lovely but more hardy and dependable. Their flowers are exceptionally large, open-faced and late flowering. Their habits are low and prostrate. Considered hardy in the range of 0 to 10°F. Mr. Gartrell was a Georgia Tech graduate who came to breeding later in life. Robin Hill was the name of his New Jersey home. I counted 69 introductions. See www.donaldhyatt.com for photos and descriptions.

- 'Antoine'—Soft shades of coral, pink, and light pink, large, hose-in-hose wavy flowers, June.
- 'Barbara M. Humphreys'—Pure white single flower covers bright green glossy leaves, one of the best.
- 'Betty Ann Voss'—Lovely double, light pink flowers on a plant that has a weeping habit and beautiful dark green foliage.
- 'Blue Tip'—Large, lavender flower with a white center.
- 'Chanson'—Pink, semi-double to double flowers.
- 'Cherie'—Deep reddish orange flowers in late May, double, hardy and compact, burgundy winter leaves.
- 'Christie'—Broad trumpet-shaped, pink flowers, low mounding growth.
- 'Congo'—Vivid reddish purple flowers on a dwarf spreading plant.
- 'Conversation Piece'—Single, rich pink, 4" diameter flowers with dots, blotches, sectors of pink, red and white, all at the same time, on a low to medium shrub, 25" by 28" in 10 years.
- 'Dorothy Hayden'—Single, open-faced, white flowers with a distinct green throat, broader than tall, 15" by 34" in 10 years.
- 'Dorothy Rees'—Large, single, pure white flower with a green throat has ruffled margins.
- 'Early Beni'—Gorgeous coral-red, hose-in-hose, semi-double with extra petals, 28" by 36" in 17 years.
- 'Eliza Scott'—Upright habit and pale pink-red single flowers.
- 'Eunice Updike'—Dwarf mounded, pale scarlet double flowers.
- 'Flame Dance'—A single, large, tubular, red flower, weeping habit.
- 'Frank Arsen'—Pink and white flowers with yellow overtones.
- 'Frosty'—The pink, single flower with a distinct dark blotch has a frosty overtone.
- 'George Harding'—Vivid red flower with a white throat.
- 'Gillie'—Single, rose-salmon.
- 'Givenda'—Single, light pink.
- 'Glamora'—Large semi-double white flowers tinted lavender, 18" by 36" in 10 years.
- 'Glencora'—A medium red, double, 2 1/2" diameter flower on a dwarf plant.
- 'Gresham'—A very large, strong pink flower that has variable stripes and sectors on a compact, dwarf plant.
- 'Greta'—A low mound that is covered with dark pink, single flowers with wavy margins.
- 'Gwenda'—Pale pink, ruffled, 3" diameter flowers, semi-dwarf growth habit, 21" by 36" in 10 years.
- 'Hilda Niblett'—Absolutely perfect mounded growth habit and large pink and white flowers; common in Southeast and one of the best "doers".
- 'Jeanne Weeks'—Fully double flowers of lavender-pink, opening flowers resemble rosebuds, compact mounded growth habit.
- 'La Belle Helene'—Strong pink flower that develops a white throat.
- 'Lady Louise'—Single to semi-double pink flower with a darker blotch.
- 'Lady Robin'—Single white with variable stripes and sectors of bright pink, some will be white flushed pink or pink with white margins, with or without stripes or sectors, broad sprawling growth, 21" by 36" in 10 years.
- 'Laura Morland'—Soft warm pink semi-double flowers with occasional darker stripes, compact growth, 16" by 23" in 10 years.
- 'Little Louise'—"Witches' broom" sport of 'Lady Louise', large pink flowers, dense small leaf mound.
- 'Maria Derby'—Bright red, double flowers, dense compact growth.
- 'Mrs. Emil Hager'—Semi-double to double "hot" pink flower that is more vibrant than most Robin Hills, 12" by 19" in 10 years.
- 'Mrs. Villars'—A white, frilled, single flower with occasional pink splashing.

- 'Nancy of Robin Hill'—Light pink, hose-in-hose flowers, broad growing, 16" by 36" in 10 years; named after Mr. Gattrell's wife.
- 'Octavian' (Formerly 'Rosenkavalier')—A light creamy pink flower.
- 'Olga Niblett'—The two Nibletts are the last two Robin Hills Mr. Gattrell named, Olga is white with a yellowish cast and a yellow throat and is one of the best.
- 'Ormsby'—Deep salmon pink, double, late May into June, dense and upright.
- 'Palmyra'—Delicate medium pink flowers, tall habit.
- 'Papineau'—White flower with a pale green throat stands out against the vigorous green foliage.
- 'Pat Erb'—Double, blush pink flowers (June) look like tiny rosebuds, compact plant with tiny, shiny dark green leaves.
- 'Peg Hugger'—Soft pink, double flowers on a compact plant.
- 'R-01-09'—This unnamed plant has a small, white flower that opens with the Glenn Dales and Backacres.
- 'Red Tip'—Single, white flower with margin of strong rose-red.
- 'Redmond'—Flat-faced, large, red, single flower.
- 'Robin Dale'—Wavy petaled, white flower with a greenish throat, pink splashing throughout.
- 'Robin Hill Gillie'—Very ruffled, flat-faced, scarlet flowers with dark blotch, dense foliage, 14" by 36" in 10 years.
- 'Robin Hill T-12-2'—Large, ruffled, white with occasional light pink stripes and a soft chartreuse blotch, June.
- 'Robin Hill T-51-1'—Large, bi-color white flowers splashed with soft pink, accented with bright rose speckling in the throat and occasional deeper pink stripes and sectors, June.
- 'Robin Hill U-10-8'—Frilled white with a chartreuse blotch, late May, low-spreading.
- 'Roseanne'—Large, ruffled, white flowers with bright pink margins, broad-spreading.
- 'Sarah Holden'—Huge, white, single flower with ruffled margins.
- 'Scott Gattrell'—Orchid pink, hose-in-hose flower with a striking dark blotch.
- 'Sherbrook'—Large, single, lavender flowers.
- 'Sir Robert'—Variable flower patterns that range from white to pink, flowers over a long period.
- 'Spink'—Delicate pink flower, the earliest of all the Robin Hill.
- 'Talbot'—Light lavender pink with a greenish white throat and an occasional white margin, June.
- 'Tan Dilly'—Strong pink often shading to tan at the tips of the petals, irregularly double, early June.
- 'Turks Cap'—A bright scarlet single flower on an upright plant.
- 'Verena'—Soft lavender, single flower, rounded habit.
- 'Watchet'—A rich pink, large, flat, single flower with ruffled margins, small leaves and mounded habit.
- 'Wee Willie'—Purplish pink, single flowers with ruffled edges.
- 'Welmet'—Single, lavender-pink flowers are large and flat-faced, as plants age they develop a white center.
- 'Wendy' (PP 10,751)—Tinted strong pink with dark pink sectors, wavy petals, mounding growth habit, late June.
- 'White Moon'—A lovely low mounded plant with huge flat wavy flowers that occasionally sport red specks or marks.
- 'Whitehead'—Large, 3", single, white flowers of great variability in various patterns of pink and white, shiny evergreen foliage, early June.

RUSTICA FLORA PLENO HYBRIDS (Azaleas)

- 'Norma'—Late flowering double rose-red with a salmon glow and vivid stamens.

RUTHERFORDIANA HYBRIDS (Azaleas)

Medium-sized flowers, 2 to 4' high, shrubby, evergreen plants with showy spring flowers, require mid-day shade, hardy to 20°F in protected location. Developed in 1920s in New Jersey as greenhouse forcing azaleas. Zone 8 to 9. Many have frilled petals.

- 'Alaska'—Semi-double, pure white.
- 'Dorothy Gish'—Orange-salmon, semi-double, hose-in-hose.
- 'Gloria'—Variegated sport of 'Dorothy Gish'.
- 'L.J. Bobbink'—Hose-in-hose, white with pinkish-lavender blush, 6 to 8' high and spreading, mid to late season.
- 'Pink Ruffles'—Flowers pink-violet, semi-double, 2" diameter.
- 'Red Ruffles'—Large, deep red, ruffled flowers.
- 'Rose Queen'—Double, rose-pink.
- 'Southern Belle' (PP 4,929)—Green leaves have creamy white margins, strong pink, hose-in-hose flower with a dark blotch, medium-sized, sport of 'Pink Ruffles'.
- 'White Gish'—White sport of 'Dorothy Gish'.

SATSUKI HYBRIDS (Azaleas)

Satsuki azaleas are lovely treasures from Japan, Satsuke meaning fifth month, the basic flowering period for most varieties. They are excellent evergreen spreading shrubs of dwarf size, featuring many flower forms and many color combinations on one plant. Large flowers appear in mid to late May to June in the Athens area. Derived primarily from *R. indicum* and *R. eriocarpum*. Considered Zone 7 to 9 adaptable.

'Amagasa'—Deep pink, 3 1/2" diameter.

'Aozora'—Pale pink flowers flecked and striped with dark pink, plant habit is low-spreading.

'Azuma Kagami'—Single, 2 1/2" diameter flowers are light pink with many variations from deeper pink at the edges to a delicate blush pink.

'Balsaminaeflorum'—Late, double, rose flowers with 40 petals or more and no pistil or stamens, low compact.

'Banka'—White flower with flecks of pink or a solid pink border on six rounded lobes.

'Beni-Kirishima'—Double, orange-red flowers on a broad-spreading plant.

'Bunkwa'—Flesh pink flowers, 2" diameter, low grower.

'Chidori'—Deep pink, single, 3 1/2" diameter flower with an inner light star, crinkled margins are intriguingly ringed with wide vivid reddish purple bands, early season.

'Chinsei'—Salmon pink flowers, small dark green, long, narrow leaves.

'Chinzan' ('Chinsayii')—Warm pink flowers, outstanding shiny, pointed, little leaves, quite dwarf and compact.

'Chojuhu'—Single, 1 1/2" diameter flowers are made of sepals instead of petals, first flowers are brilliant red, changing to orange and light brown, and remain until winter, upright-spreading habit.

'Coral Cascade'—Large, single, coral-pink flower with white blotches, spreading, cascading branches.

'Daisetsu-zan'—Extremely large, white flowers with yellow-green centers adorn this dark green, heavy-textured plant, collected by Dr. John Creech from the nursery of Mr. Yoshiyuki Shibahata in Japan.

'Eikan'—Extremely variable, white, ruffled, 4" diameter flowers with all combinations of pink and rose, vigorous, spreading plant.

'Eiten'—Mallow purple.

'Flame Creeper'—Orange-red, low, dense.

'Fuku Ro Kuju'—Pristine white flowers with an occasional red fleck, shiny dark green leaves.

'Geisha'—White flowers often streaked with reddish purple, wide upright.

'Geisha Girl'—Deep rose and white.

'Getsutoku'—Large, single wavy petals are white with variegation of pink and salmon stripes or solid colors of shade mentioned.

'Gumpo Fancy'—Low growing, small, narrow leaves, large, bi-colored flowers have slightly wavy, white margins and a pink center, late flowering.

'Gumpo Pink'—Most common Satsuki in South, soft pink ruffled petals on a compact plant.

'Gumpo Red' (sometimes listed as Red Gumpo)—Red, low-spreading, compact, late flowering.

'Gumpo Rose'—Darker rose flower, otherwise like above.

'Gumpo White'—Large single white frilled flowers with occasional purple flecks, dense habit, late flowering.

'Gunbi'—A sport of 'Gumpo' that is white with reddish flecks and stripes, large 3" diameter flowers have ruffled lobes, compact habit.

'Gunrei'—Frilled showy white with pink flecks, low growing.

'Hakusen-No-Mai'—Semi-double white flower with green blotch, has the appearance of snowflakes.

'Haru-No-Hikari'—Huge salmon-white, variable, single.

'Heiwa'—White with shadings of pink and rose.

'Higasa'—Extremely large, 4 1/2" diameter flat flower, deep rose-pink with paler pink on margins.

'Hitoya-No-Haru'—Large, rose-mauve variable single.

'Ho Koku'—Low, mounding plant, deep pink flowers, often surrounded by a prominent white border in June.

'Issho No Haru'—A variable flower of lavender and white with many forms and combinations.

'Johga'—White to light pink or purple, 2 1/2 to 3" diameter flowers with occasional flecks of purplish pink, reddish dots in blotch, low mound, 2 to 3' high.

'Juko'—Medium-large, single, wide pointed petals of light orchid-pink, speckled or striped with deeper pink, some solid flowers of pink or rose, or edged with white, small foliage, tight habit.

'Kaempo'—Late flowering dwarf hot pink, particularly showy, *R. kaempferi* × *R. 'Gumpo'*.

'Kayo-No-Homare'—Flower has a white center, bordered orange-red, with an occasional sport of white with pink stripes and deep pink solids, has slightly pointed petals, slow growing round habit.

'Kazan'—Showy, salmon-orange flowers, dwarf, foliage is waxy deep green.

'Keigetsu'—Light pink flowers and a striking red margin, green leaves are variegated with flecks of white, low-spreading plant.

'Keisetsu'—Strong red, 3" diameter flowers with a light pink to white center, unusual variegated leaves.

- 'Kimi-Maru'—A light pink flower with deeper pink edges may have many variations, single with medium round petals, small leaves and a slightly open form.
- 'Kinpai'—Early flowering, white-centered flowers with variations of coral, buff or reddish orange border, some flowers are solid red or orange.
- 'Kisarazu'—Clear white sometimes blushed pale pink with deeper pink margin flowers, late May into early June, compact.
- 'Kobai'—Large red flowers with occasional circles of white on six, round, overlapping lobes, descriptively called 'Red Plum'.
- 'Kokan'—Small, growing plant with a 1 1/2" long leaf that curls inward, making a tubed leaf.
- 'Ko-Kinsai'—Lacy, coral salmon, single flower with split spider like petals, foliage is small and the plant has a low, bushy habit.
- 'Komeno No Yuki'—White with variable flakes, sectors and selfs of deep pink, low-growing, June.
- 'Kozan'—Small, delicate shell pink flowers with individual rounded petals, slow growing plant.
- 'Linda R'—Sport of 'Eikan', large, soft shell-pink, flat-faced, ruffled flowers, dense plant habit.
- 'Mai-Hime'—Extremely variable flowers, rose pink to white, low grower.
- 'Matsu No Hikari'—White and orange-red with variable stripes and sectors on 3" diameter, ruffled flowers with overlapping petals.
- 'Matsuyo'—White flowers with selfs, flushes and streaks of strong pink, late June.
- 'Miyuno no Tsuki'—Flowers white with heavy stripes of reddish pink and occasional all pink flowers.
- 'Mt. Baldy'—Single white flowers with a white throat and rose marking, unusual dense foliage with leaves curved inward for a tube-like effect.
- 'Myogi'—Flowers are light pink with dark pink stripes and flakes, 'Gumpo' type compact growth.
- 'Negligee'—Pale pink, 2" diameter flowers with a scattering of darker pink dots on the upper petal, very low, rounded mound.
- 'Nyohozan'—Soft pink flowers have deep pink to red spotting in the center, leaves are small and covered with hairs, slow growing, flowers appear large in scale to the leaves, compact plant.
- 'Orchid Empress'—Large, deep orchid, double flowers, dark green foliage, compact habit, mid-season hybrid introduced by the late C.S. McCorkle, 3 to 4' high.
- 'Otome'—White flowers with many light pink and yellowish pink variations, even occasional stripes of salmon pink, slow growing habit, low to medium height.
- 'Rinpu'—Means "long lasting wind", leaves are curled, twisted and contorted as if blown by the wind, flowers are medium pink, with a darker flare, slow growing dwarf, to 1' in 10 years.
- 'Rukizon'—Small salmon-red flowers on a dense small plant with tiny 1/2" long leaves, also known as 'Kazan'.
- 'Sakuragata'—White petals finely edged in purple, very low-spreading, late June into July.
- 'Shiko'—Large, wide, lavender-pink, variable, single.
- 'Shinkigen'—White flower with many variations of sectors and marks of pink and red with round overlapping petals.
- 'Shinnyo-No-Tsuki'—Large, white centers, rose border.
- 'Shinnyo-No-Tsuki' (Sport)—Large with crimson blotches in the flowers, foliage with creamy stripes longitudinally throughout.
- 'Shira Fuji'—Unusual white markings on green foliage, white flowers, sometimes with purple.
- 'Shugetsu' ('Autumn Moon')—Large, 3 to 4" diameter flowers are white with deep purple border, or variations of completely white or purple, taller than wide in habit.
- 'Shumpow'—Rose pink flower with purple or white variegations, good dense growth habit.
- 'Summer Sun'—Orange-red flower with pointed lobes, related to *R. indicum* or *R. eriocarpum*.
- 'Tai Fuki'—White flower that may be one-half bright red.
- 'Tochi-No-Hikari'—Low growing plant with extremely deep red, 4 to 5" diameter flowers.
- 'Tsuki-no-Hitomaru'—Flowers peach, pink, and white with stripes, flecks and borders and rounded, slightly separate petals, vigorous, full and upright grower.
- 'Uki Funei'—Foliage variegated with spots and speckles of yellow, funnel-shaped flowers are generally white, but also developing stripes and spots of pink, low-spreading plant.
- 'Un-Getsu-No-Hikari'—Flower is salmon-pink edged with a spotted coral red throat and has small, single, pointed petal, slow growing.
- 'Unzon Tao Tsigi'—Small leaves, low-spreading plant, small pinkish flowers.
- 'Wakaebisu'—Light salmon-pink flowers with deeper pink dots in the blotch.
- 'Yachiyo Red'—Flower is frosty white with a beautiful pastel pink blush, variable rose pink markings occur as streaks, spots and along the margins of the petals, plant is low and compact.
- 'Yaye'—Large ruffled white, chartreuse throat and occasional salmon stripes, late May into June.

SLONECKER HYBRIDS (Azaleas)

- 'Chetco'—Bright yellow flowers, orange blotch.

SOMMERVILLE HYBRIDS (Azaleas)

From Earl Somerville, Marietta, GA; offered by Mountain Shadow Nursery; many have *R. flammeum* in the saplines; the significant issue is the unbridled proliferation of these and other deciduous native azaleas—too many, too similar, short WOW-window; in flower, magnificent; out of flower . . . nobody recognizes them.

'Ed Stephens'—Bright red-orange in ball-shaped truss; long red stamens.

'Jack Melton'—Red flowers, globe-shaped truss; glossy green foliage; *R. flammeum* selection.

'Orange Carpet'—Bright orange flowers; bright green foliage; sterile; low-spreading habit, 18" by 8' in 45 years; *R. calendulaceum* × *R. flammeum*, collected from Allatoona Lake area in Georgia.

'Pink Ember'—Pink with yellow blotch; compact habit, 3' by 3' in 25 years; (*R. bakeri* × *R. viscosum*) × *R. arborescens*.

'Razzberry'—Raspberry-pink with bright yellow blotch; bushy habit; 4' by 4' in 45 years; *R. flammeum* × *R. periclymenoides*.

'Sommerville Pink'—Rich pink buds open white flushed pink in center; good foliage; 12' by 8' in 15 years; *R. flammeum*.

'Vivian Abney'—Medium pink with yellow blotch, outer edges of petals lighter pink; 4 to 6' by 4 to 6'; thought to be *R. flammeum* × Exbury?

SONOMA HYBRIDS (Azaleas)

I have yet to see a plant but the list is long. Developed by Stewart Barber in the 1960s and 1970s. Used *R. nakaharae*, various Satsukis, etc. Apparently, most of the information on parentage was lost.

VUYKIANA HYBRIDS (Azaleas)

Several plants were growing in Mt. Airy Arboretum, Cincinnati, OH before −25°F obliterated them, probably −5 to −10°F at best.

'Double Beauty'—Large, double, deep rose flowers, fast grower, sport of 'Vuyk's Rosy Red'.

'Palestrina'—Super hardy, strong, upright, large specimen, single, white flowers have a large, yellow-green flare and a soft fragrance.

'Vuyk's Rosy Red'—Rosy pink, wavy margined flowers in May, dark leaves, tidy habit on a 2' mounded plant.

'Vuyk's Scarlet'—Bright scarlet-rose flowers, large, deep glossy green leaves, excellent plant habit.

'Wilhelmina Vuyk'—Ivory-white, tall growing.

WINDSOR HYBRIDS (Azaleas)

Originally from Windsor Great Park/Savill Gardens in England. Introduced into the U.S. by the late Wells Nursery, Penrose, NC.

'Burning Light'—Stunning coral red flowers with an orange throat.

'Windsor Appleblossom'—An unusual multi-colored specimen that ranges from cream to deep pink, with a compact shape.

'Windsor Buttercup'—Brilliant clear yellow, heavy flowering, excellent shape.

'Windsor Daybreak'—A blend of dawn colors that is most fascinating, with a compact shape.

'Windsor Peach Glow'—A superb orange yellow, with an upright habit.

'Windsor Pink Souffle'—An extremely vigorous plant with soft pink flowers, trusses are large.

'Windsor Ruby'—A compact plant with large, deep red flowers.

'Windsor Sunbeam'—A darker yellow than 'Windsor Buttercup' with good shape and heavy flowering capabilities.

Rhododendron Hybrids

DEXTER HYBRIDS

Many of the rhododendrons that Charles O. Dexter of Sandwich, MA created from 1921 to 1943 were of a quality that had not previously been available. Noted for their fine, dense foliage, large stature and wonderful flowers and colors. Precise records of his crosses do not survive, but he appears to have used at least the following species: *R. decorum* Franch., *R. fortunei* Lindl. subsp. *discolor* (Franch.) D.F. Chamb., *R. griersonianum* Balf. f. & Forrest, *R. haematodes* Franch., and *R. fortunei* Lindl. The influence of *R. fortunei* is dominant in his plants, so much so that all widely distributed Dexter hybrids are referred to as Fortunei Hybrids. Hardy in the vicinity of −10°F and depending on cultivar has 5°F leeway from this number. Significant collection of Dexter hybrids at Heritage Plantation, Sandwich, MA which was the home of Mr. Dexter. Mid-May to mid-June is the optimum time for experiencing the rhododendrons in flower. Walked the Dexter Collection and was largely overwhelmed. Simply too large, too many, too similar. 'Scintillation' broke the log-jam and is relatively common because it has the good garden features (q.v.).

'Ben Moseley'—Slightly frilled, bright pink flowers with dark blotch.

'Betty Arrington'—Large, conical trusses of fragrant, pink flowers accented by ruby markings in the upper petals.

- 'Betty Hume'—Large, frilly, pink flowers, slight fragrance, large, bold foliage, compact, mounding plant to 6'.
 'Brown Eyes'—Hardy pink with a brown blotch, introduced by Paul Bosley, Sr., Mentor, OH.
 'Champaign'—Opulent creamy yellow, overlaid with pink, to 4' high.
 'Dexter's Champagne'—Apricot flowers, spreading habit, olive green foliage.
 'Dexter's Count Vitette'—Mound-like plant, multi-branched, spreading habit, pale lavender flowers, full trusses.
 'Dexter's Giant Red'—Large, red-orange flowers fade to crimson with deep red and lighter red spots throughout, vigorous, upright habit.
 'Dexter's Purple'—Lovely lilac-purple flowers of excellent substance.
 'Dexter's Spice'—Extremely fragrant, large white flowers gently spotted with green on a full, lush plant.
 'Dexter's Vanilla'—Delicate fragrance, multi-colored pink and white flowers, light bluish green foliage.
 'Dexter's Victoria'—Frilly, deep pink with deeper throat flowers, mid to late May, 4' by 4' in 20 years.
 'Dorothy Russell'—Rounded mounding habit, glossy foliage, rose-red flowers.
 'Edgemont'—Large, rosy pink flowers, large growth habit.
 'Frances Shannon Racoff'—Deep purplish pink shading to lighter pink in the throat, glossy dark green foliage, 8' by 10' in 25 years, from Winterthur, -15°F.
 'Gi-Gi'—Rose-red flowers covered with deep red spotting.
 'Gloxineum'—Prolific flowering with enormous pastel pink flowers.
 'Governor's Mansion'—Found by Dexter at the governor's mansion in Asheville, NC, royal purple flowers have a bronze-yellow throat, glossy dark green foliage.
 'Great Eastern'—Large light pink flowers, petals edged in light red, deeper red throat, floriferous, hardy.
 'Hal Bruce'—Soft pink buds open to light cream-yellow with slight pink highlights, glossy dark green leaves, 8' by 5' in 25 years, named for former Winterthur garden curator, -15°F.
 'Josephine Everitt'—Free-flowering, pure pink flowers, with a definite lighter center, well-shaped trusses, vigorous growing.
 'Kelley'—Light red flowers with attractive dark spotting on all petals, medium growth habit.
 'Lady of Belfield'—Late flowering, pink flowers with darker blotches adorn this tall pyramidal plant, magnificent foliage, 6' high.
 'Merley Cream'—Large, creamy white flowers with a yellow flare, rounded, well-formed plant, medium green leaves.
 'Mrs. W.R. Coe'—Intense pink.
 'Parker's Pink'—Deep pink flowers shading darker at the margins and lighter near the center for a near bi-color effect.
 'Paul R. Bosley'—Pink with a red blotch, mid-May, long, dark green, recurved foliage.
 'Pink Satin'—Deep, rich pink flowers with a satiny finish, large trusses on a compact plant.
 'Powder Puff'—Candelabra effect as rosy buds elongate and open to soft lilac-pink, outstanding in the garden.
 'Sagamore Bayside'—Ball-shaped truss of lavender-pink flowers, wavy edges, yellow green spotting and stripe down the center, late May.
 'Scintillation'—The best known of all Dexter rhododendrons and the most common in cultivation, luminous light pink flowers with an amber throat, good substance and heat resistance, lustrous dark green leaves on a compact plant, 6' high, excellent form and has performed magnificently in Zone 7.
 'Skyglow'—Peach-edged pink.
 'Todmorden'—Strikingly intense rose-pink and white flowers giving nearly a bi-color effect, tall growing.
 'Tom Everett'—Frisled soft sensuous pink with pale yellow throat, extremely floriferous, low-spreading growth.
 'Warwick'—Mauve-pink.
 'Wheatley'—Frisled vivid pink flower with yellow blotch.
 'Wissahickon'—Bright rose.
 'Wyandanch Pink'—Shiny bright pink flowers, handsome rugose and convex leaves on an upright plant, 6' high, quite hardy.
 'Zoë Graves'—Mauve with deep red blotch, glossy dark green leaves, 10' by 6' in 25 years, Winterthur introduction, -15°F.

FINNISH HYBRIDS

Many years past, Dr. Paul Cappiello showed me these cold hardy, large-leaf rhododendrons that he was testing in Orono, ME (University of Maine). I have yet to witness them in flower (except in photos) but they have surfaced at specialty nurseries. All (to my present knowledge) are considered flower bud hardy to -25°F. This breeding program started in 1973 at Helsinki University and initial breeding lines, especially *R. brachycarpum* D. Don ex *G. Don* subsp. *tigerstedtii* Nitz. (GRIN does not accept the variety as a legitimate taxon) was selected as a source of hardiness. The species has dark green leaves covered by brownish pubescence below, cream-white flowers, flushed pink, June–July. Japan, Korea. The program utilized 53 individuals as maternal parents, 23 species and 48 hybrids as paternal. From 22,000 hybrid

- seedlings, the number was reduced to 80, with 9 cultivars released. Temperatures as low as -38°F in the mid 1980s provided the best possible screening. These and the Northern Lights azaleas have proven themselves hardy in Anchorage, Alaska, where they flowered in late May–early June. Cultivars include:
- 'Elvirra'—First released from the program in 1986; cherry red flowers on a compact early-flowering bush; about 3' high and wide at maturity.
 - 'Haaga'—Pink flowers on an upright growing bush; about 5 to 6' high at maturity.
 - 'Helsinki University'—Light pink flowers on an upright growing bush; about 7' high at maturity; may be the hardiest as it is rated to about -40°F .
 - 'Kullervo'—Pink flowers fading to white on a compact shrub; about 4' high.
 - 'Mikkeli'—White with pink-tinted flowers, late blooming; leaves dark green with a light pubescence covering young shoots and unopened leaves; tall form.
 - 'Pekka'—Light pink flowers with light green leaves; prolific flowerer.
 - 'Peter Tigerstedt' ('P.M.A. Tigerstedt')—Flowers white with a brown blotch on a tall shrub, more than 7' high at maturity.
 - 'Pohjola's Daughter' ('Pohjolan Tytär')—White with a green-brown blotch, flower buds bright violet-red; compact habit, about 3' high.

LEACH HYBRIDS (*Rhododendrons* and *Azaleas*)

- Hybridized by the late Mr. David Leach, North Madison, OH, possibly the world's greatest authority on the subject. Mr. Leach was extremely discriminating and did not introduce a new cultivar unless it met rigid standards for quality of flower, foliage, habit, and hardiness.
- 'Anna H. Hall'—A semi-dwarf, apple blossom pink and white.
 - 'Argentina'—Bright rosy red flowers, ball-shaped trusses of 25 flowers, well-shaped vigorous plant.
 - 'Bali'—Soft pink flowers with a creamy yellow throat, 6 1/2' by 9' in 30 years.
 - 'Bangkok'—Orange blended into pink, hardy to -15°F .
 - 'Borneo'—Amber-colored flowers, unique blend of orange, yellow, and red.
 - 'Bravo'—Hardy deep pink, described as "a huge, blowzy, Rubenesque sort of rhododendron with buxom trusses."
 - 'Brittany'—Flowers open pale yellow, transform into two shades of pink, densely foliated, perfect mound, small, rounded leaves.
 - 'Burma'—Cardinal red flowers, broad-spreading habit.
 - 'Canary Islands'—Deepest yellow flowers to date, handsome foliage, mounded specimen.
 - 'Casanova'—Pink buds, long lasting, yellow flowers, glossy leaves, extremely fertile, 4 to 5'.
 - 'Dolly Madison'—Early flowering white, strong, tall grower, very hardy.
 - 'Edmond Amateis'—Pure white with a bold red blotch emphasized by twin rays, glossy leaves, upright dense plant.
 - 'Figi'—Claret rose-colored flowers with a yellow-orange tone to the throat, late-flowering, spreading habit, matte green leaves.
 - 'Finlandia'—White flowers form ball-shaped trusses opening from pink buds, recurved, glossy leaves, well-branched, rounded plant, excellent hardiness.
 - 'Golden Gala'—Creamy white flowers having a faint greenish throat, buds first show as magenta-rose, then open to a warm cream, deep forest green leaves, hardy, rounded shrub, to 3'.
 - 'Hawaii'—Frilly, deep rose-pink flowers open in May with an almost iridescent glow, compact 4' plant, very good foliage.
 - 'Hindustan'—Warm orange flowers are flushed with soft pink, dome-shaped trusses, wavy edges of the petals give a frilled effect, leaves twice as long as wide, deep fir green, plant grows as wide as tall, hardy to -10°F , 6'.
 - 'Hong Kong'—Pale yellow.
 - 'Ivory Coast'—White flowers with a warm ivory cast in April, small leaves that are chartreuse green in summer with a gold cast in winter, hardy, 3' by 3' in 10 years.
 - 'Janet Blair'—A lovely lavender-pink flower with a greenish throat, 6' high, -10°F .
 - 'Jeric(h)o'—P.J.M. type, small leaves, mounding habit to 3' by 5', soft yellow flowers in late April.
 - 'July Jester'—Red, late flowering.
 - 'July Jewel'—Blazing scarlet flowers in July, small plant, mildew-proof, matte green foliage, matures at 3'.
 - 'July Jubilation'—Fragrant, bright red flowers with a light orange blotch, mid-July, branches well, matures at 3'.
 - 'Last Hurrah'—Saucer-shaped, white flowers in September–October, complete trusses, habit is very low, growing three times wider than tall.
 - 'Lodestar'—Large white flowers with a prominent flare of green-gold flecks, dense foliage.
 - 'Madrid'—Dark pink with maroon blotch, 5' by 6' in 10 years.
 - 'Malta'—Small leaved form with small semi-double rose-like pink flowers.
 - 'Mist Maiden'—Rose-colored buds open apple blossom pink and fade to white, a slightly faster growing form with beautiful indumentum.

- 'Monaco'—Warm yellow flowers framed by a rosy red reverse and deepened by an olive-yellow flare, broad and rounded plant, narrow leaves.
- 'Montego'—Violet purple flowers deepen to darkest magenta with a green flare, ball-shaped trusses, dark green leaves, colorful reddish stems.
- 'Monterey'—Bright pink luminous flowers with a lighter center, broad and compact, free-flowering, hardy.
- 'Nepal'—White flowers emerge from rose pink buds, leaves are dark green with a slight wave, hardy, 6'.
- 'Nile'—Light yellow.
- 'Normandy'—Bright rose pink with deeper edges and tangerine spotting, broad to 4', late May.
- 'Nuance'—A pastel blend of yellow, orange and pink.
- 'Persia'—Reddish purple flowers have bold, yellow-green spotting, almost conical habit, hardy, 5'.
- 'Pink Flourish'—Large trusses of brilliant pink flowers shading to a lighter center and sporting a small, golden flare, vigorous grower.
- 'Pink Plush'—One of the smaller flowered, more dainty azaleas, flowers late, flowers of rose pink with deeper orange-rose on the upper petal.
- 'Pink Puff'—Small airy flowers of soft rose-pink with a showy golden yellow flare on the upper petal, late-flowering, deep green foliage.
- 'Red River'—Radiant red flowers with lighter centers in full pyramidal trusses appearing very late in the season, large leaves, vigorous growth habit.
- 'Rio'—Large, salmon pink flowers shading darker at the edges and enhanced by a golden yellow throat, in full trusses, glossy leaves, compact broad plant.
- 'Samoa'—Bright red flowers that are faintly spotted on the upper petal, compact plant, to 5'.
- 'Senegal'—Light yellow, open-faced flowers, small-leaved plant, rounded, mounding habit reaches 3' by 3' at maturity.
- 'Serenata'—Large trusses of light orange flowers with heavy substance, upright-spreading habit.
- 'Shanghai'—Vigorous, hardy hybrid, 6', large, pale pink flowers are edged with a deeper pink and a strong spot of orange yellow on the upper petal, up to 18 flowers in a tight round truss, narrow, good looking foliage.
- 'Small Wonder'—Compact, brilliant red.
- 'Spellbinder'—Tightly formed trusses of light pink, ruffled flowers marked with a spattering of red, heavily textured, unusually shiny leaves, free-flowering, well-rounded, tall grower.
- 'Spring Frolic'—White flowers emerging from pink buds, broad-rounded plant, dense, well-retained foliage.
- 'Sumatra'—Clear scarlet, dwarf, densely foliated.
- 'Summer Glow'—Late-flowering, large trusses of incandescent pink flowers in summer, vigorous.
- 'Summer Snow'—Late-flowering with white, funnel-shaped flowers, large, vigorous grower.
- 'Summer Summit'—Large plant with a vigorous habit, large trusses of ruffled, white flowers in July, height to 8'.
- 'Tang'—Hardy, opens orange with a darker reddish orange margin, upright-growing.
- 'Tennessee'—Buds of strong purple-pink open to light purple-pink flowers that change to pale yellow-pink with a bold dorsal blotch of red, smooth, elliptic foliage.
- 'Tow Head'—Low-spreading and rounded to 2', smothered with creamy yellow clusters of flowers in early May.
- 'Trinidad'—An ivory center is surrounded by a bright cherry-red edging, showy but not strident, flowers open in mid-season in large trusses on a spreading shrub.
- 'Tuscany'—Sister of the well-known 'Party Pink', flowers of soft pink accented by a red blotch, good foliage and plant habit, 5'.
- 'Venus'—Light pink flowers with darker centers, early May, 6'.

MEHLQUIST HYBRIDS (Rhododendrons)

- 'April White'—Beautiful double, white flowers on a medium growing, upright plant with relatively small leaves, leaves hold 2 to 3 years, change to yellow when senescing, 3'.
- 'Connecticut Yankee'—Large, vigorous, deep purplish blue, greenish, yellow-splotched flowers, tight dome-shaped trusses, hardy, 5'.
- 'Dorothy Swift'—Compact habit, dark foliage with heavy beige indumentum, flowers are pink in bud and open a lovely soft pink, hardy, compact habit.
- 'Firestorm'—Scarlet red flowers, dark green foliage, early June, compact, 6', twice as wide as high, see *HortScience* 27(5):480-481 (1992).
- 'Gustav Mehlquist'—Clear red flowers, grows 3 to 4' tall by 4 to 6' across.
- 'Ingrid Mehlquist'—Exceptional foliage with light indumentum on the underside of the leaf, buds heavily, pink buds open to pristine white flowers with faint crimson spotting on the upper petal, 3'.
- 'Scarlet Romance'—Bright red flowers in early June, dense, low grower, 6', twice as wide as high.
- 'White Peter'—White with purple blotch, buds lavender-pink, grew 8.6' by 14.2' in 28 years, lustrous dark green foliage, see *HortScience* 27(5):480-481 (1992).
- 'Wojnar's Purple'—Dark purple with a reddish purple blotch, hardy, fir green foliage, 5'.

RAISE THE ROOF SERIES (University of Connecticut)

- 'Buzzer Beater'—9' by 12'; yellow or light yellow.
- 'Hoopla'—Pink with yellow throat.
- 'Huskymania'—Bluish purple, more so than other purple types and extremely cold hardy.
- 'March Madness'—Rose colored with a small red flare; parentage *R. calophytum*.
- 'Slam Dunk'—Wine-colored flower with a black blotch.
- 'Tip Off'—White with a large red blotch in upper throat; *R. calophytum* hybrid.

MISCELLANEOUS RHODODENDRONS

No clear cut home so they are included here in alphabetical order.

- 'Abe Arnot(t)'—Orchid purple flowers with a heavy blotch on the upper lobe spreading into the throat and adjacent lobes.
- 'Andrew Paton'—Early flowering, large shiny leaves, well-shaped habit, full trusses of white 3" diameter flowers contrast with their raspberry red markings.
- 'Arctic Pearl'—White flowers.
- 'Arsen's Pink'—Dense, compact dwarf with clouds of pink flowers, shading to white.
- 'Asia'—The dark orange buds open to large salmon-pink flowers with a lighter yellow center, a distinctive color for a hardy hybrid, mounded habit.
- 'Ben Foster'—Compact mound, deep pink flowers, reddish stems add colorful interest during the growing season.
- 'Big Red'—Large, upright trusses of bright red flowers, large dark green foliage, wide and upright-growing.
- 'Black Eye'—Deep red-purple flowers have distinct "black eye" on upper lobe, 5' high.
- 'Blue Boy'—Vibrant violet funnel-form flowers of good substance to 2 1/2" diameter.
- 'Blue Lagoon'—Mystical, smokey blue-purple flowers have a large and prominent deep purple eye, recurved, deep forest green foliage.
- 'Blue Rhapsody'—Large purple trusses, blotch of dark purple on the upper petal and throat, white stamens, 5' high.
- 'Bow Bells'—Deep pink buds open to light pink flowers, slow growing mounded small shrub, bronze-copper new growth.
- 'Carousel'—Low growing plant, full, wide mass of small lavender pink flowers, spotted in the throat, dark green leaves.
- 'Clement Bowers'—Deep rosy pink flowers in tight trusses, compact and vigorous, shiny fir-green foliage.
- 'Conestoga' (*R. minus* × *R. racemosum*)—Bright pink flowers, low growing twiggy small leaf plant.
- 'Damozel'—Brilliant red, hardy in the Atlanta area, it also grows well in Gainesville, FL, excellent foliage on spreading upright plant.
- 'Deming Brook'—Creamy white flowers kissed with a pink tinge at the edges, low dense mound.
- 'Dorothy Amateis'—Large trusses are deep purple with a deeper purple eye, foliage is an olive mat-green and the leaves are held in an upright position, 5 to 6'.
- 'Edith Bosley'—Large, rich, royal purple flowers, darker blotch in the center, vigorous, 5 to 6'.
- 'Fairy Mary'—Densely foliated mound, flowers are white to light yellow with pink and apricot.
- 'Floda'—White flowers marked with pink stripes radiating through each petal, and a suffusion of yellow-appearing in the garden as shrimp pink, semi-evergreen, fabulous red fall color, hardy and reliable.
- 'Friday'—Huge satin purple flowers, black-velvet blotch on the upper petal, each flower petal in the round trusses folds back, showing those delightful deep blotches, foliage is medium mat-green and leathery textured, good habit, 5'.
- 'Giganteum'—Spherical trusses of bright crimson flowers, hardy, rolled leaves, vigorous habit.
- 'Ginny Gee'—Flowers about an inch across, in groups of 11 buds, with 4 or 5 flowers each, party-pink, kissed with white, compact plant to 2' high.
- 'Goethe'—Large pastel lavender flowers enriched by brownish red spotting, rounded trusses.
- 'Hardgrove's April Snow'—Small rounded plant, pure white flowers, foliage is small, pointed and deep green.
- 'Hockessin'—Apricot flowers soften to white, hardy small-leaved dwarf.
- 'Honshu's Baby'—White flowers with pale purple-pink margins from buds that are a strong purplish-pink, conical trusses of 4, tight dense mounded plant, 1' high.
- 'Hortulanus H. White'—Orange yellow flower, moderate in size with a strong orange blotch.
- 'Hudson Bay'—White flowers, small leaves turn bronze in winter, branches freely, 3' by 4'.
- 'Humboldt'—Frilled trusses of mauve sport dusky brown-red eyes on the upper petals of each flower, foliage handsome kelly green, habit is upright.
- 'Hurricane'—Flowers are a beautiful pink with markings of deep pink, vigorous growing, compact plant, 5'.

- 'Hyperion'—White flowers with chocolate blotch, dark green foliage, 5'.
- 'Independence Day'—Red flowers with lighter centers and a deep ruby blotch on the upper lobe in June.
- 'Intaglio'—Miniature mound reaches only 8" high, spreads to 3', delicate flowers are white touched with clear pink, leaves are a brilliant green.
- 'Irresistible Impulse'—Large trusses of deep red purple, each flower has a large deep purple blotch on the upper lobe, deep green leaves have a leathery texture, 5'.
- 'Joe Paterno'—White truss splashed with yellow, extremely hardy.
- 'Joshua'—Large scarlet red flowers in a good sized truss, compact plant, slight twist to the dark green leaves.
- 'Juan de Fuca'—Deep rosy lilac flowers have an enriching red blotch and spotting, emerald green leaves, upright.
- 'June Magic'—Pastel pink flowers in June, excellent habit, glossy foliage.
- 'Ledikanense'—Attractively colored green leaves, wide-spreading and rounded, light lavender-pink with reddish spotting in the throat.
- 'Lemon Tea'—Delicate yellow and pink flowers.
- 'Matilda'—Great blue color, small-leaf, hardy variety, becomes more dense as it matures.
- 'Mini Brite'—Delicate mound, flowers are blended colors of yellow and pink with red spotting.
- 'Mrs. Charles E. Pearson'—Light pink flowers with brown spots, vigorous plant, to 6' high, lush foliage.
- 'Olin O. Dobbs'—Deep waxy red-purple flowers in large and compact trusses that are a perfect conical shape, much like 'Mars' in growth and plant habit, 4'.
- 'Orange Honey'—Unusual pink-orange flowers in each truss, vigorous growing with a slightly open habit.
- 'Party Pink'—Large round trusses of soft pink, hardy and strong growing to 5'.
- 'Patty Bee'—Dwarf, yellow flowers with outstanding small, fir green leaves, suitable for rock gardens or foreground.
- 'Paul Vossberg'—Bright red flowers enriched with a dark garnet flare in full, rounded trusses, low, well-branched and mounded plant, spinach green leaves.
- 'Peach Blend'—Pink flowers with a yellowish center in April, fast-growing when young, nearly deciduous.
- 'Peter Vermeulen'—Dark glossy 'Scintillation' foliage on strong stems, rosy pink flowers in full trusses, free-flowering and hardy, well-shaped, easily grown plant.
- 'Pikeland'—Puffs of pink flowers with darker pink wavy edges and spots, well rounded semi-dwarf.
- 'Pioneer'—Heavy flowering, flowers from clear pink to bluish tinged in early April, hardy, upright, 4 to 5' by 4 to 5'.
- 'Pioneer Silvery Pink'—Many silvery shades of pink, 4 to 5', more evergreen and later than 'Pioneer', early May.
- 'Princess Anne'—Beautiful yellow flowers on a compact plant, early May, bronze foliage in winter, 2'.
- 'Red Brave'—Compact, vigorous plant, dark red flowers in full trusses with white anthers.
- 'Red Eye'—Deep red-purple with a most interesting eye, when the flower first opens the eye is green gold, becoming red, foliage is shiny, medium sized, and dense, withstands heat well, 5'.
- 'Red Frilled'—Funnel-shaped, light red-purple flowers, glossy dark green leaves, broad-spreading growth habit, 3', hardy.
- 'Redder Yet'—Bright red flowers in a round truss.
- 'Rik'—Clusters of white flowers edged with pink, foliage in winter has red leaf and stem color.
- 'Rosemarie'—A very fine blue-violet with larger flowers than 'Purple Gem' or 'Ramapo' but not quite as hardy, compact to 3'.
- 'Roslyn'—Long leaves and violet purple flowers with lighter centers characterize this fine plant, the 2" diameter, ruffled flowers are held in a truss of twelve.
- 'Spring Song'—Soft yellow flowers changing to apricot on a small, compact mound.
- 'Staccato'—Silvery pink, semi-double, ruffled flowers, early spring.
- 'Swamp Beauty'—Magnolia purple buds which open to heavenly deep rose-pink with a maroon blotch which is solid in the throat, flaring to spots on the upper petal, foliage is medium fir green, vigorous, to 5'.
- 'Tapestry' (PP 11,155)—Trusses of purple flowers with a dark flare in late May, chunky, compact-growing plant, dark green foliage.
- 'Taurus'—Unbelievable red with large trusses, in full flower April 29, 2005 at Swarthmore; impressive flowers but foliage was not the best.
- 'Veronica Pfeiffer'—Shapely flowers with frilled lobes of an exquisite light purple shade, plant is well proportioned.
- 'Wee Bee'—Deep reddish pink flowers, dwarf plant, small flat leaves with scaly indumentum on a dense mound.

NEARING HYBRIDS (Rhododendrons)

- 'Brandywine'—Ball-shaped trusses of 2" diameter, cream-colored flowers edged in rose, small, narrow hairy foliage, upright habit.
- 'Chesapeake'—Small leaves, long, willowy stems, small, light pink flowers appear in early April.
- 'Cliff Garland'—Petite trusses of shell pink flowers, small, rounded leaves, flowers early.
- 'Delaware'—Flowers apricot shading to white, small leaf.
- 'Elsmere'—Lemon yellow flowers, small-leaved plant.
- 'Flamingo'—Rich coral.
- 'Lenape'—Light yellow flowers, narrow leaves, upright habit.
- 'Mary Belle'—Ruffled flowers, mixed peach, coral and yellow.
- 'Mary Fleming'—Small-leaved variety, low-spreading to 3', flowers are pale yellow with blotches and streaks of salmon.
- 'Montchanin'—Graceful and willowy, adds diversity and interest, clusters of small white flowers near the ends of their slender branches make a welcome display.
- 'Purple Imp'—Bright bluish violet flowers in clusters early in the season, upright, vigorous, spreading plant, small shiny leaves, good heat tolerance.
- 'Wyanokie'—White.

SHAMMARELLO HYBRIDS (Rhododendrons and Azaleas)

For more than 40 years, A. M. "Tony" Shammarello hybridized and selected a group of large-leaved rhododendrons derived primarily from the standard ironclad cultivars. His goal was an extended season of flowers on compact bushy plants that are hardy around Lake Erie. He succeeded admirably. It is only a matter of time before they become more widely known and grown, not just as collectors items, but for their value as fine landscape plants.

- 'Belle Heller'—Enormous trusses of large glistening white flowers with throats flecked with gold, vigorous tall grower, tends toward loose open habit, has performed well in Zone 7.
- 'Besse Howells'—Ruffled burgundy red flowers accented by a dark red blotch, compact like 'Boule de Neige', very floriferous and hardy.
- 'Elie'—Rounded trusses are cerise pink with a deeper pink flare, medium-sized, glossy green leaves.
- 'Elsie Lee'—Large frilled bluish lavender semi-double, 2 to 3" diameter flowers, upright and compact to 3 to 4', late May, orange-red and yellow fall leaves.
- 'Helen Curtis'—White, double flowers, broad-spreading, mid-sized plant.
- 'Hino-White Dwarf'—Sport of 'Hino-White', early-flowering, white, spreading with dwarf habit.
- 'Holden'—Rosy red flowers illuminated by a small dark red blotch, flowers fade to pink when fully open, one of the best for Zone 7, buds consistently every year, medium height with lustrous dark green foliage.
- 'Ice Cube'—Ivory white flowers accented with a lemon blotch, dark green foliage, medium height.
- 'Lavender Queen'—Broad rounded habit to 5'; rounded trusses of small, ruffled, light bluish lavender flowers in late May—early June; glossy dark green foliage.
- 'Pink Cameo'—Hardy compact plant to 5', fresh pink flowers that have a deeper pink blotch.
- 'Red Red'—Flowers appear mid-season and are approximately 2" in size, after 10 years this plant will be 2' by 3' in size.
- 'Rocket'—Slightly ruffled, deep, radiant, coral-pink with a scarlet-red blotch, lustrous dark green foliage.
- 'Sham's Juliet'—Compact grower, apple blossom pink flower with a rich chocolate blotch.
- 'Sham's Pink'—Light two-tone vivid pink flowers are darker at the edge with a light red blotch, low-spreading.
- 'Sham's Yellow'—Golden buds open to large frilled lemon-yellow flowers.
- 'Spring Dawn'—Rosy pink flowers with golden yellow blotch, mid-May, vigorous, 5 to 6'.
- 'Spring Glory'—Pink flowers that have a deeper pink marking, vigorous growing, compact habit.
- 'Spring Parade'—Glowing scarlet-red flowers cover a compact plant, dark green leaves, very hardy.
- 'Tony'—Bright cherry red, mid-May, attractive crinkled foliage, low growing, 4' by 4' in 10 years.

Rhodotypos scandens (Thunb.) Mak. — Black Jetbead

(rō-dō-tī'pōs skan'denz)

FAMILY: Rosaceae

LEAVES: Opposite, simple, ovate to ovate-oblong, 2 1/2 to 4" long, half as wide, acuminate, rounded at base, sharply and doubly serrate, bright green and glabrous above, lighter green and silky beneath when young, prominently parallel-veined (ribbed); petiole—1/8 to 1/4" long.

BUDS: Imbricate, brownish green, divergent, glabrous, slightly stalked, ovoid.

STEM: Young—green, glabrous, shiny, eventually turning brown; old—gray-streaked, reddish brown, orangish lenticels.

SIZE: 3 to 6' in height by 4 to 9' in spread, in native haunts may grow to 15' but under cultivation I have never seen anything larger than 6'.

HARDINESS: Zone 4 to 8.

HABIT: Mounded, loosely branched shrub with ascending and somewhat arching branches, often of shabby appearance; perhaps unduly harsh for I have observed handsome (too strong) colonies and masses; the key is to not expect too much from the species.

RATE: Medium to fast.

TEXTURE: Medium in leaf; coarse in winter.

LEAF COLOR: Various authors report dark green as the typical summer foliage color; however, I feel the color tends toward a bright green; fall color is green with a slight tinge of yellow; one of the first shrubs to leaf out in spring.

FLOWERS: Perfect, white, 1 to 2" diameter, 4-petaled (unusual for Rosaceae), 4-lobed calyx, May to early June (mid to late April, Athens), borne singly at the end of short twigs, not outstanding but interesting upon close inspection.

FRUIT: Drupe (have seen listed as a tumid berry), 1/3" long, ellipsoidal, glabrous, hard, 3 to 4 in a group, shining black, October and persistent into the following spring and summer; neither flowers nor fruits are showy but do offer a degree of interest in the garden.

CULTURE: Readily transplanted; very tolerant of differing soil conditions; tolerates full sun or shade; crowding and polluted conditions; pH adaptable; one of the better shrubs for adverse conditions and heavy shade.

DISEASES AND INSECTS: Largely trouble free, although a twig blight, *Nectria cinnabarina* was reported.

LANDSCAPE VALUE: Tough, durable plant for rugged conditions; good in shady areas, shrub borders, massing on banks and under shade trees; there are too many superior ornamental shrubs to justify extensive use of this species; in early November, 1997, I witnessed a planting in a parking lot island at Bernheim Arboretum, still green but thinking about blushing yellow, in full blazing exposure it was in terrific condition; considered invasive in eastern U.S., I have yet to witness its escape.

PROPAGATION: Softwood cuttings taken in late spring root readily; actually easy to root any time the plant is in leaf. Seed apparently requires acid scarification and a cold period.

NATIVE HABITAT: Japan, Korea, and central China. Introduced 1866.

Rhus aromatica Ait. — Fragrant Sumac

(rös a-rō-mat'ik-a)

FAMILY: Anacardiaceae

LEAVES: Alternate, trifoliate, leaflets subsessile, ovate, the terminal 1 1/2 to 3" long, acute or acuminate, cuneate and often obovate; the lateral ones oblique and rounded at the base, about one half as large, all coarsely toothed, lower surface pubescent becoming glabrous, variable in leaf coloration but often a glossy medium to dark green; petiole—1 to 1 1/2" long.

BUDS: Small, yellow, pubescent, covered by leaf scar.

STEM: Slender, pubescent, aromatically fragrant when bruised, leaf scars circular, distinctly raised.

SIZE: 2 to 6', possibly larger, with a spread of 6 to 10', extremely variable in size over its native range; have seen 6' high and wide mounded shrubs on occasion.

HARDINESS: Zone 3 to 9.

HABIT: Low, irregular spreading shrub with lower branches turning up at the tips; tend to sucker from the roots and produce a dense, tangled mass of stems and leaves.

RATE: Slow to medium.

TEXTURE: Medium in leaf, medium in winter habit.

LEAF COLOR: Medium green, almost blue-green effect, often glossy on the upper surface; fall color orange to red to reddish purple, coloring best on light soils.

FLOWERS: Polygamous or dioecious, yellowish, mid to late March–April, borne in approximately 1" long catkins (male) or short panicles at ends of branches (female); male catkin persistent and exposed through late summer, fall and winter.

FRUIT: Red (female plants only), hairy drupe, 1/4" diameter; August–September and may persist into winter but usually loses its good color.

CULTURE: Fibrous root system, easily transplanted from containers; adaptable, withstands 1/2 to 3/4 shade or full sun; prefers acid, well-drained soil, has not performed well in campus plantings at Georgia.

DISEASES AND INSECTS: None serious although various wilts, leaf spots (caused by *Pezizella ornotherae*), powdery mildew, rusts, cankers, aphids, mites, and scales have been noted.

LANDSCAPE VALUE: Excellent fast cover for banks, cuts and fills, massing, facing; could be used as ground cover especially the low growing cultivars; this plant has the ability to develop roots as the stems touch the soil and is therefore useful for stabilizing banks or slightly sloping areas.

CULTIVARS:

'Green Globe'—Grows to 6', forms a rounded, dense shrub.

'Gro-low' ('Gro-Low')—Low, wide-spreading habit, excellent glossy foliage, 2 to 3' high, 6 to 8' wide, good looking plant; a female with yellow flowers and hairy red fruits, fall color is a good orange-red, introduced by Synnesvedt Nursery, Glenview, IL; popular in the Midwest; utilized on Georgia campus but consistently melted/died out, perhaps because of heavy, wet soils, replaced with dwarf *Myrica cerifera* and *Itea virginica* which have fared much better; may require tip pruning to keep it in the 2' range.

'Konza'—Listed to 10', although Ferruci Nursery tagged height at 2'; leaves turn dark red in fall; heavy fruit production; drought tolerant; selected from limestone outcrops south of Manhattan, KS by USDA Plant Material Center.

Several varieties are listed by various authors but their botanical validity is questionable.

PROPAGATION: Seed, scarify for 60 minutes; and provide 1 to 3 months cold stratification or fall sow; softwood cuttings, July, 1,000 ppm IBA gave 100% rooting in peat:perlite under mist; root cuttings will also work.

ADDITIONAL NOTES: In my mind this shrub is somewhat of a second class citizen but I have bumped into hundreds over the years and cannot remember any that were offensive. The bright yellowish flowers, especially on male plants, were always welcome after a difficult midwestern or eastern winter. The foliage has a certain sparkle and in fall, excellent reddish purple coloration may develop. When a planting becomes overgrown, it can be easily rejuvenated with a large mower, bush hog or other instrument of destruction.

NATIVE HABITAT: Vermont and Ontario to Minnesota, south to Florida and Louisiana. Introduced 1759.

RELATED SPECIES:

Rhus trilobata Nutt. ex Torr. & A. Gray, (rös trī-lō-bā'ta), Skunkbush Sumac, is quite similar to *R. aromatica* and appears to be its western ally. It is an upright or ascending shrub, 3 to 6' high, with leaves and flowers smaller than *R. aromatica*. Flowers are more greenish and fruits slightly smaller than *R. aromatica*. The leaves are more unpleasantly scented. It makes a handsome and almost impenetrable mass, which would lend itself to roadside and similar landscape sites. 'Autumn Amber' is low growing with prostrate branches, the plant tends to produce dense thickets, about 1 to 1 1/2' high, 8' wide, the dark green leaves brilliant yellow and red in fall, greenish yellow flowers appear in early spring, sex is unknown but no fruits have been produced; originated from seeds collected near Littlefield, TX, found on limestone outcroppings and would be a good ground cover for high pH soils; hardy to Zone 4; see *HortScience* 21:1465–1466 (1986). Variety *malacophylla* Munz. with diffuse pubescent branches to 5' high, cuneate-obovate leaflets, yellow flowers, is found in California. Native from Illinois to Washington, California and Texas. Introduced 1877. Zone 4 to 6? Has been lumped with *R. aromatica* in RHS Plant Finder 2008–2009.

Rhus typhina L. — Staghorn Sumac

(rös tī-fē'na)

LEAVES: Alternate, compound pinnate, entire leaf 1 to 2' long, 13 to 27 leaflets, often 19, each leaflet lance-oblong, 2 to 5" long, 1 to 2" wide, acuminate, serrate, bright green above, glaucous beneath, pubescent when young; petiole—about 2" long, hairy; in fact, entire rachis maintains some pubescence.

BUDS: Hairy, leaf scars not elevated and somewhat C-shaped.

STEM: Stout, rounded, densely velvety hairy, concealing the lenticels, almost club-like; pith large, brownish, aromatic when broken.

SIZE: 15 to 25' in a landscape situation; potential to 30 to 40' in the wild; spread is usually equal to or greater than height; national champion is 57' by 41' in Tallapoosa, AL.

HARDINESS: Zone 4 to 8.

HABIT: A large, loose, open, spreading shrub or a gaunt, scraggly tree with a flattish crown and rather picturesque branches resembling the horns on a male deer; hence, the name Staghorn; spreads by root suckers to form large colonies.

RATE: Fast when development occurs from root suckers; slow to medium on old wood.

TEXTURE: Species—medium in summer, coarse in winter; cultivars ('Laciniata' and 'Dissecta')—fine in foliage, coarse in winter.

STEM: Dense, velvety reddish brown pubescence persisting on 2- and 3-year-old branches; older stems gray and relatively smooth.

LEAF COLOR: Bright green in summer, yellow, orange and scarlet in fall; often spectacular; leaves out late in spring.

FLOWERS: Dioecious, greenish yellow, June to early July; female borne in dense, hairy panicles, 4 to 8" long; male in a bigger, looser, wider panicle.

FRUIT: Crimson, late August through April, densely hairy drupe, closely packed in a pyramidal panicle; bright crimson in early fall, becoming duller and darker red with cold weather and often still colorful even into spring.

CULTURE: Easily transplanted, adapted to many soil types; however, prefers a well-drained soil, not a plant for poorly drained areas; tolerates very dry, sterile soil; often seen along railroad tracks and highways; suckers profusely and tends to form wide-spreading colonies; tolerates city conditions; can be rejuvenated by cutting to ground in later winter.

DISEASES AND INSECTS: Same as described under *R. aromatica* except *Verticillium* was reported on Staghorn Sumac.

LANDSCAPE VALUE: Massing, naturalizing, waste areas, perhaps banks, cuts and fills; actually hard to kill this plant due to its ability to sucker freely from roots; should not be used as a specimen, foundation or container plant; the cutleaf forms offer superb texture and even better yellow-orange-red fall coloration, quite coarse in winter and considerable thought should go into proper siting.

CULTIVARS: Coombes, *The New Plantsman* 1(2):107–113 (1994), discusses the cut-leaved sumacs.

'Dissecta'—Similar to 'Laciniata' but leaflets more deeply divided; discovered in the late 1800's by a Massachusetts nurseryman; foliage is quite beautiful and colors handsomely in fall; a female.

'Laciniata'—Leaflets deeply divided creating a fine-textured, ferny appearance; a female, much like 'Dissecta' which is perhaps more finely divided, had both in Illinois and had a difficult time differentiating especially from more than 10' away.

Tiger Eyes® ('Bailtiger', PP 16,185)—First witnessed in 1998 with Don Selinger at Bailey's, St. Paul, MN and uttered the magic word . . . WOW; discovered in Bailey's fields as a chimera, slowly increased by root cuttings; beautiful, bronze-yellow new growth, settles to yellow, yellow-green in July—

'Laciniata'

August, then orange-red in fall, finely dissected foliage akin to 'Dissecta' and 'Laciniata', not as rampant as the green leaf forms; tested in Georgia trials for 6 years and has held color in heat and drought, definitely will sucker but not like the green-leaf types; probably 5 to 10' at maturity; everyone who sees it asks the identity; certainly eye-catching; female and will produce the panicles of reddish drupes.

PROPAGATION: Seed, scarify for 50 to 80 minutes in sulfuric acid; cuttings, root pieces collected in December placed in moist sand:peat yielded plants in 2 months; the cultivars 'Dissecta', 'Laciniata' and Tiger Eyes® are produced by root cuttings.

ADDITIONAL NOTES: Large genus comprising some 150 to 200 species of evergreen and deciduous shrubs and trees in temperate and subtropical climates worldwide. The best garden qualities reside in the North American species, *R. aromatica*, *R. copallina*, *R. glabra*, and *R. typhina*. The beautiful autumn color and rich red fruits are the principal attributes. Utilize with the knowledge that most will sucker and require maintenance. In 1987, while in West Berlin (the Wall still existed), I noticed *R. typhina* in the grassy medians. Photos from the bus window are still in my files. Also, in the great garden at Hidcote, *R. typhina* was growing in a large container. Europeans have long appreciated *R. glabra* and *R. typhina*. Perhaps, someday, Americans will become more introspective and appreciative of our rich woody plant heritage.

The only other *Rhus* I encountered (beyond *R. radicans* L., now *Toxicodendron radicans* (L.) Kuntze, Poison Ivy, with 3, rarely 5 or 7, leaflets, cream to yellow-green flowers, 1/4" diameter cream to light brown drupes, vine-like to shrubby habit and *R. verniciflua* Stokes, now *Toxicodendron vernicifluum* (Stokes) F.A. Barkley, Varnish Tree, Chinese Lacquer, or Japanese Lacquer Tree, with 7 to 13 leaflets, 3 to 6" long, 1 to 3" wide, ovate-oblong, entire, dark green, 50 to 70' high) are *R. potaninii* Maxim., a large shrub or small tree to 25' with 7 to 11 leaflets, off-white flowers and red, densely pubescent fruits, Zone 6; and *R. virens* Lindh. ex A. Gray, Evergreen Sumac, a shrub to 10' (co-national champions 14' by 27' in Comal, TX, and 15' by 16' in Uvalde, TX) with 5 to 9, to 1" long, lustrous dark green, evergreen leaflets, Zone 8 to 9. Have seen *R. potaninii* Maxim. at Hidcote and the Arnold Arboretum and *R. virens* at Stephen F. Austin Arboretum in Nacogdoches, TX.

NATIVE HABITAT: Quebec to Ontario, south to Georgia, Indiana and Iowa. Cultivated 1629.

RELATED SPECIES:

***Rhus chinensis* Mill.** — Chinese Sumac
(rös chi-nen'sis)

LEAVES: Alternate, compound pinnate, 8 to 15" long, 7 to 13 leaflets, subsessile, ovate to ovate-oblong, 2 to 5" long, about half as wide, acute or short acuminate, coarsely crenate-serrate, lustrous bright green above, brownish pubescent beneath, rachis and often the petiole conspicuously winged, pubescent.

BUDS: Pubescent, almost woolly, gray-brown in color, leaf scars not elevated, C-shaped.

STEM: Yellowish brown, glabrous to minutely pubescent, lenticels prominent.

Rhus chinensis, Chinese Sumac, is a loose, spreading, suckering shrub or flat-headed tree growing to 24' in height and width. The foliage is bright green in summer and can change to orangish red tones in fall but this color is seldom realized in the Midwest; however, I have seen excellent yellow-red fall color on a plant at the Arnold Arboretum. Foliage was killed by spring freeze in early April 2007, regrowth occurred. The flowers are yellowish white, August into September, borne in 6 to 10" long and wide panicles. Panicles may be twice this size on vigorous specimens. The fruit is a densely pubescent, orange-red drupe that matures in October. Best used in large areas, naturalistic settings, possibly the shrub border; valued mainly for its late flower. Dr. Orton, Rutgers University, introduced 'September Beauty' which has immense panicles, and is superior to the species. Also offers good fall color, which in the Dirr garden was apricot-yellow in early to mid-November. Unfortunately, the species and 'September Beauty' are excessively aggressive and I was removing stray shoots three years after excavation of the parent plant. Utilize where lateral space is plentiful. Manchuria, China, Japan, Korea, Malaysia. Introduced 1737, cultivated 1784. Zone 5 to 7(8).

***Rhus copallina* L. — Flameleaf (Shining) Sumac**
(rös ko-pal-lī'na)

LEAVES: Alternate, compound pinnate, 6 to 12"(16") long leaf, 9 to 21 leaflets, oblong-ovate to lance-ovate, 1 3/4 to 4" long, usually acute, entire or sometimes with a few teeth near the apex, glabrous and lustrous dark green above, usually pubescent beneath, rachis winged, pubescent.

BUDS: Pubescent, reddish brown.

STEM: Terete, reddish, puberulous; leaf scars U-shaped, not as coarse as *R. chinensis*, *R. glabra*, and *R. typhina*.

Rhus copallina, Flameleaf or Shining Sumac, is compact and dense in extreme youth becoming more and more open, irregular and picturesque as it ages, with crooked, ascending and spreading branches; broader at the top. Grows 20 to 30' high with a similar spread. Co-national champions are 29' by 32' in Pontotoc County, MS, and 35' by 24' in Bullitt, KY.

The foliage is lustrous dark green in summer changing to rich red, crimson, and scarlet in fall. Fall color often burgundy-maroon and not quite as vivid as that of *Rhus glabra* and *R. typhina*. Flowers (dioecious) are greenish yellow, July to August, borne in dense, 4 to 8" long, 3 to 4" wide panicles. Flowered September 3, 2004 at the Raulston Arboretum. The fruit is a pubescent, crimson drupe which ripens in September to October. One of the best sumacs; useful for dry, rocky places, banks, large areas, and naturalistic plantings. Almost pestiferous in the South but certainly beautiful in the fall. A few disclaimers are needed to temper my exuberance. The species shows no penchant toward uniformity and usually forms large spreading colonies. For the small garden, it has no place. I have observed tremendous variation in fall color and believe the best form(s) should be vegetatively propagated. Use with discretion for the plant may turn on you tomorrow. 'Creel's Quintet' is a more restrained form, 8 to 10'(15') high, suckering, with 5 lustrous dark green leaflets that turn burgundy in fall, female, a single plant in the Georgia trials failed to impress and was removed. Have also heard of another compact form. The late Gary Lanham, Lebanon, KY has discovered purple and yellow leaf summer foliage forms. Have observed both and color fades with the heat of summer. Variety *latifolia* Engl. Prairie Flame™ ('Morton') grows 4 to 6' high, spreading by suckers, lustrous dark green leaves, flaming orange-red to red in autumn, male, flowers in July–August (Chicago), Zone 5, introduced from Morton Arboretum via Chicagoland Grows®. Full flower July 29, 2007 at Raulston Arboretum. A handsome, dense shrub just coming into flower August 26, 2006 at Schmidt's, Boring, OR. GRIN merges var. *latifolia* with the species. Maine to Ontario and Minnesota south to Florida and Texas. Cultivated 1688. Zone 4 to 9.

***Rhus glabra* L. — Smooth Sumac**
(rös glā'bra)

LEAVES: Alternate, compound pinnate, 12 to 18" long, 11 to 31 leaflets, lance-oblong, 2 to 5" long, 1/2 to 3/4" wide, acuminate, serrate, medium to deep green, glaucous beneath, rachis normally red.

BUDS: Pubescent, round, ovoid, with leaf scar almost completely encircling bud.

STEM: Stout (thick), glabrous, somewhat 3-sided, green to reddish and covered with a waxy bloom; leaf scar horseshoe-shaped.

Rhus glabra, Smooth Sumac, grows 10 to 15' high with a comparable spread.

Usually grows in colonies as it suckers and develops in all directions from the mother plant. This is very evident in plantings which occur along roadsides and other low maintenance areas. National champion is 52' by 28' in Drybranch, GA. The foliage is medium to dark green in summer changing to excellent yellow to orange-red-purple combinations in fall. Flowers are dioecious, greenish yellow, June–July, borne in 6 to 10" long panicles. Mid June, Chapel Hill, NC. Fruit is a scarlet, hairy drupe which persists late into winter. Good plant for mass plantings, highways, dry, poor soil areas. The essential difference between this species and *R. typhina* is the lack of pubescence on the young stems. This is the more common species, compared to *R. typhina*, in the Piedmont of Georgia.

'Laciniata' has leaflets which are deeply cut and lobed. It is female and will produce the bright scarlet fruits. It was discovered in the mid 1800's near Philadelphia. In 1994, Allen Coombes, Botanist, Hillier Arboretum, named what I believe is the typical 'Laciniata', *R. x pulvinata* Greene 'Red Autumn Lace'. This is a hybrid between *R. glabra* and *R. typhina* and, indeed, 'Red Autumn Lace' has intermediate pubescence on leaves and stems. 'Morden's' ('Morden Selection') is a more restrained form to 6' with bright red fruits. See Coombes, *The New Plantsman* 1(2):107–113 (1994), for the "Cut Leaved Sumacs." Also, Lancaster, *The Garden* 115 (10) 531–533 (1990), waxes poetic about *Rhus glabra*.

Maine to British Columbia, south to Florida and Arizona. Found in all contiguous 48 states into northern Mexico. Cultivated 1620. Zone 3 to 9.

Rhus michauxii Sarg. — Michaux's Sumac
(rös mi-shō'ē-ī)

LEAVES: Alternate, compound pinnate, 9 to 15 leaflets, 2 to 4" long, oval-oblong, acuminate, coarsely serrate, lustrous dark green and pubescent above, densely brown pubescent below, rachis winged below the terminal leaflets.

STEM: Densely hairy.

Rhus michauxii, Michaux's Sumac, is essentially unknown in commerce but is worthy of mention because of the low-growing, 2 to 3' high, suckering constitution. The large, coarsely toothed leaves turn rich reddish purple in fall. Yellow-orange fall color just developing on a handsome colony at the University's Botanical Garden on October 14, 2001. Yellow-green flowers occur in a 6 to 8" long panicle in June–July and in female forms are followed by red, pubescent, compressed drupes. North Carolina to Georgia. Introduced 1806. Zone 5 to 7.

Ribes alpinum L. — Alpine Currant
(rī'bēz al-pī'nūm)

FAMILY: Grossulariaceae

LEAVES: Alternate, simple, roundish or ovate, 1 to 2" long and wide, 3- rarely 5-lobed, with obtuse or acute dentate lobes, truncate or subcordate, bright green; petiole—about 1/2" long, glandular hairy.

BUDS: Stalked, large, imbricate, distinctly gray-tan in winter.

STEM: Light to chestnut brown, often lustrous, with conspicuous ridges running down from edges of leaf scars, unarmed, as stems mature, exfoliation may occur.

SIZE: 3 to 6'(10') high, usually as wide or wider.

HARDINESS: Zone 2 to 7.

HABIT: Densely twiggy, rounded shrub; erect in youth with stiffly upright stems and spreading branches.

RATE: Medium.

TEXTURE: Medium-fine in leaf; medium in winter.

STEM COLOR: Straw-colored on young stems; old becoming deep brown and shredding.

LEAF COLOR: Deep bright green in summer, poor yellow in fall; one of the first shrubs to leaf out in spring.

FLOWERS: Dioecious, greenish yellow, April, staminate with 20 to 30 flowers in 1 to 2" long racemes; female smaller, with 10 to 15 flowers, not showy, on racemes one-half as long.

FRUIT: Juicy scarlet berry, 1/4 to 1/3" diameter; June–July; attractive but seldom seen in cultivation as male clones seem to dominate; not edible.

CULTURE: Easily transplanted, best handled as a container plant; tolerant of any good soil; full sun or shade; prune anytime for flowers are not a factor; does well in calcareous soils.

DISEASES AND INSECTS: Anthracnose, cane blight, leaf spots, rust, currant aphid, imported currant worm, scales, and currant bud mite; during wet seasons leaf spot and anthracnose can be serious problems; male supposedly immune to rust diseases.

LANDSCAPE VALUE: Good hedge plant and is used for that purpose, mass, good in semi-shady areas; male plants tend to dominate because of supposed rust resistance; occasionally plants with perfect flowers occur.

CULTIVARS:

'Aureum'—Dwarf type with yellowish leaves, colors best in full sun and supposedly maintains the color throughout summer, although have noted references that state yellow-green in summer; has been in cultivation since before 1881.

'Europa'—Good, leaf-spot-resistant foliage, on a densely branched, 3 to 5' high 6 to 8' wide, female shrub; listed by Midwest Groundcovers, St. Charles, IL.

Green Jeans™ ('Spreg')—Selected for its superior summer leaf retention, bright, glossy green foliage remains clean and persists; female; 3 to 5'(6') high and wide; Spring Meadow Nursery introduction.

'Green Mound'—Dwarf, dense, 2 to 3' (4') high and wide form; shows good resistance to leaf diseases; have also seen 'Nanum', 'Pumilum' and 'Compacta' listed, essentially more compact than species.

PROPAGATION: Softwood cuttings taken in June or July rooted well when treated with 1,000 ppm IBA and placed in sand under mist; seeds may be fall sown or provided 3 months cold stratification.

ADDITIONAL NOTES: Great number (150) of species in the north temperate regions. Many species are thorny, and of no garden merit, others are important for fruit production with *R. alpinum* and *R. sanguineum* the most important garden species. Informative article by Neil Bell 2006, Currents and gooseberries give us springtime goosebumps. *NMPro* 22(8):12–13, 81.

NATIVE HABITAT: Europe. Cultivated 1588.

RELATED SPECIES:

***Ribes aureum* var. *villosum* DC.** (formerly *Ribes odoratum* H.L. Wendl.) — Clove, Buffalo, Missouri Currant (rī'bēz a'rē-um vil-lō'sum)

LEAVES: Alternate, simple, ovate or orbicular-reniform, 1 to 3" wide and as long, deeply 3- to 5-lobed, cuneate or truncate, with coarsely dentate lobes, glabrate or puberulous beneath, bluish green, thinnish; petiole—1/2 to 2" long.

STEM: Pubescent, grayish brown.

Ribes aureum var. *villosum*, Clove Currant, grows 6 to 8' high and is an irregular shrub of ascending, arching stems, usually surrounded by a mass of young suckering growth, loose and open with age. It is not the neatest shrub and selection for dwarf attributes would be worthwhile. Foliage is bluish green in summer; briefly yellowish just before dropping in fall (may have reddish tones). Flowers (dioecious) are yellow, fragrant, odor of cloves; early to mid-April; borne in 5- to 10-flowered, usually nodding racemes. Fruit is a black berry, 1/3" across, June or July. A yellow-fruited forma, *xanthocarpum* Rehd., is known. 'Crandall', with 3/5" diameter, edible fruits and mildew resistant foliage, is listed. Good shrub for the border or where early spring color is desired. It is an alternate host for White Pine Blister Rust (*Cronartium ribicola*). Native from South Dakota to western Texas, east to Minnesota and Arkansas. Zone 4 to 6(7).

Ribes aureum Pursh, Golden Currant, is similar with spicily fragrant, yellow flowers. Fruits are rounded, small, purple-black. Have seen on occasion and could not separate it from *R. odoratum*. Please note the name change according to GRIN. I was right all the time, i.e. essentially no difference. Western United States to Mexico.

Ribes sanguineum Pursh. — Winter Currant
(rī'bēz san-gwin'ē-um)

LEAVES: Alternate, simple, 3- to 5-lobed, 2 to 4" wide, cordate, dark green above, whitish pubescent below; petiole—glandular pubescent.

Ribes sanguineum, Winter Currant, is a West Coast species that is seldom seen in eastern gardens. The habit is upright-arching to rounded, maturing between 6 to 10'(15'). The flowers of the better cultivars are exceptional. White, pink, rose-red flowers appear in pendulous, 3" long racemes along the length of the stems during April–May. Fruits are bloomy, bluish black, slightly glandular, 1/3" diameter berries. Plants prefer moist, well-drained soil in full sun or partial shade and will tolerate a modicum of drought. As a shrub border plant, it is particularly attractive. Have walked through wood/forests in the Portland, OR area where the species is common in the understory. Native to British Columbia to northern California. Cultivated 1818. Zone 5 to 6(7).

CULTIVARS: Cultivars listed by United States nurseries include:

'Apple Blossom'—Deep pink buds, soft white-pink flowers; may be the same as 'Pokey's Pink'.

'Barrie Coate'—Pink-red flowers.

'Brocklebankii'—Yellow leaves that fade with the heat of summer and may scorch in hot sun; pale pink flowers; common in English and Scottish gardens, usually with buds expanding and showing rich color in late March with full flower development in April; a shrub in full flower is spectacular, another plant that gardeners lust after; have seen in Dr. Richard Weaver's former garden in the Boston area.

'Claremont'—Soft pink flowers.

'Elk River Red'—Rich red flowers.

'Emerson'—Deep pink flowers, upright growth habit.

'Hannaman White'—White flowers in long racemes.

'King Edward VII'—Red flowers; quite compact, about 5 to 6' high,

Mary's Peak™—Bright coral 3 to 4" long racemes; a *R. xgordonianum* Lem. selection, parentage *R. odoratum* × *R. sanguineum*.

'Mesa Red'—Soft red flowers in 2 to 3" long inflorescences.

'Montara Rose'—Light pink flowers on an 8' high plant.

'Pokey's Pink' ('Poky's Pink')—Clear, medium pink flowers.

'Pulborough Scarlet'—Deep red flowers; spectacular in full flower.

'Spring Showers'—Large, pinkish red panicles.

'Spring Snow'—White flowers.

'Tydermann's White' ('Tydeman's White')—Deep green leaves and white flowers.

'Variegatum'—Cream-splashed leaves and rose-red flowers.

Icicle™ (White Icicle™, 'Ubric')—White flowers in 2 to 3" long inflorescences on an 8' high plant.

Additional species that I witnessed include: *Ribes laurifolium* Jancz., an evergreen groundcover shrub with large, leathery leaves and racemes of greenish white (more white than green) flowers in late winter. Always bump into this plant during our March visits to English gardens; at Spinners along the drive, in full flower March 2, 2006. Grows 1' by 3'. Probably only suited to West Coast. Western China. Introduced by E.H. Wilson in 1908. *Ribes speciosum* Pursh is a semi-evergreen shrub, usually grown as a wall shrub in England. The leaves are lustrous green, the stems and fruits with bristly red stems. Flowers remind of fuchsia: slender, rich red, in a pendant inflorescence in April–May. Beautiful wall planting at Knightshayes. Again, best on West Coast. California. Introduced 1878.

Robinia pseudoacacia L. — Black Locust, also Common Locust, Yellow or White Locust
(rō-bin'ē-a sō-dō-a-kā'sē-a)

FAMILY: Fabaceae

LEAVES: Alternate, pinnately compound, 6 to 14" long, 7 to 19 leaflets, elliptic or ovate, 1 or 2" long, entire, mucronate at apex, rounded or truncate, dark bluish green, glabrous beneath or slightly pubescent when young.

BUDS: Terminal—absent, laterals—minute, rusty-downy, 3 to 4 superposed, generally close together.

STEM: Slender, brittle, often zig-zag, light reddish to greenish brown, smooth or nearly so, more or less angled with decurrent ridges from base and outer angles of leaf scars, generally spiny with paired stipular prickles at nodes, about 1/4 to 1/2" long, prickles larger and more prominent on sucker and rapid shoot extensions.

SIZE: Would average 30 to 50' in height with a spread of 20 to 35' although can grow 70 to 80' high; national champion is 94' by 68' in Livingston, NY.

HARDINESS: Zone 4 to 8(9).

HABIT: Often an upright tree with a straight trunk and a narrow oblong crown, becoming ragged and scraggly with age; will develop thickets as it freely seeds, and develops shoots from roots; some forms are spreading in habit with several trunks.

RATE: Fast, will average 2' or greater per year over a 10 year period.

BARK: Reddish brown to almost black, deeply furrowed into rounded, interlacing, fibrous, superficially scaly ridges; I see large deeply ridged-and-furrowed trunks that are gray-black, seldom red-brown.

LEAF COLOR: Dull, dark blue-green above, very strongly contrasting with the light and dark green of other trees;

Three Leaflets

leaves show a slight yellow-green in fall and may abscise early; in Georgia, trees hold leaves late, often into mid-November.

FLOWERS: Perfect, 1" across, white, extremely fragrant, borne in dense racemes, 4 to 8" long in May to early June, flowers at a young age, effective for 7 to 10 days; flowers mid to late April in Athens.

FRUIT: Pod, flat, brown-black, 2 to 4" long, smooth, 4- to 10-seeded, maturing in October and persisting for a time.

CULTURE: Transplants very easily, extremely adaptable to varied soils and climates; will grow in about any soil except those that are permanently wet; reaches maximum development on moist, rich, loamy soils or those of limestone origin; tolerant of dry conditions and saline environments; will grow on sandy, sterile soils; has the ability to fix atmospheric nitrogen and in this way partially creates its own nitrogen supply; this is true for many legumes as well as alders, bayberry, sweetfern and others; prune in late summer or fall for locusts "bleed" in spring.

DISEASES AND INSECTS: Canker, dampening-off, leaf spots, powdery mildews, wood decay, witches' broom, locust borer, carpenterworm, locust leaf miner, locust twig borer, and scales; the most destructive pest is the locust borer which can riddle whole trees or whole plantations; the wood is extremely hard and durable yet this borer can destroy it like balsa wood; tree vigor is the important factor, for fast-growing trees exhibit the greatest resistance; leaf miner also turns the tree brown in summer.

LANDSCAPE VALUE: An "alley cat" type tree which can survive under the toughest of conditions; good for stripped-mined areas, highway cuts and fills, sandy, poor soils, shelter plantations and afforestation purposes; not recommended for the home landscape, but definitely has a place in difficult areas; the flowers are fragrant, from which bees produce a delicious honey; several cultivars offer attractive foliage and flowers.

CULTIVARS: The Europeans have grown, appreciated and selected superior forms of this tree while Americans treated it as some pedestrian weed. In truth, it often makes, in the best forms, a handsome tree. Several of the cultivars have crossed my path. There are many others that I may never see but it will not be for a lack of trying. I understand that the U.S. Forest Service has developed borer resistant clones. Use in cultivated situations must be tempered with the knowledge that borers and leaf miners can render trees unsightly or dead. During sabbatical in 1999, I witnessed 'Bessoniana', 'Casque Rouge', 'Coluteoides' (small tree/large shrub), 'Frisia', Twisty Baby™, 'Pyramidalis', 'Rehderi' (12' by 15', multistemmed shrub), 'Rozynskiana', 'Tortuosa', 'Umbraculifera' (25' by 25'), and 'Unifoliola'.

'Aurea'—New leaves emerge yellow and the color persists for a time but eventually becomes lime-green, plant at Arnold lost yellow color in early summer; cultivated since 1864, found in Germany around 1859.

'Bessoniana'—Ovoid crown, well-developed central leader, essentially unarmed stems; vigorous constitution and shy flowering characterize this form; in cultivation before 1871, have seen at Wisley Gardens; has great blue-green foliage; leaflets larger than species; could not find stipular spines on the specimen at the Milliken Arboretum; no flowers evident.

Chicago Blues® ('Benjamin')—Upright with oblong crown, 50' by 35'; blue-green foliage; fragrant white flowers; minimal prickles; borer resistant; selected from seedlings near O'Hare Airport by Chicago City Forester, Bob Benjamin, offered by Beaver Creek Nursery.

'Dean Rossman'—A seedling selection with pale yellow leaves, color supposedly holds better than 'Frisia'.

'Decaisneana'—A vigorous tree with light rose flowers, first described in 1863, supposedly comes partially true-to-type from seed, considered more properly a hybrid and is listed under *R. xambigua* Poir. (*R. pseudoacacia* × *R. viscosa* Vent.); branches slightly glutinous, stipular thorns small or absent; witnessed at Kew many years past.

Fibermaster™—Maintains a straight, controlled growth habit, compared to the irregular growth habit that is typical to the species.

'Frisia'—Leaves of a golden yellow color which hold (more or less) throughout the growing season; spines on young shoots red; discovered in an old nursery in 1935 at Zwollerkerspel, Holland; I noticed this form in abundance throughout Europe and it was a rather cheerful sight especially on some of the drab, dreary, rainy days; some older leaves become more yellow-green but overall it holds the yellow color as well as any colored foliage tree; displays excellent vigor; has become popular in Northeast and West but even in those cooler climates loses much (most) of the yellow leaf color; still colorful at Schmidt Arboretum, late August 2007.

'Purple Crown' (PP 7,731)—Vigorous, narrow upright crown of branches, abundant purple flowers, discovered in a row of seedlings at Princeton Nursery; considered a cross between *R. hispida* and *R. pseudoacacia*; mildly fragrant flowers; nearly thornless branches when mature; heat, drought and high pH tolerances.

'Purple Robe'—One of the prettiest forms with dark rose-pink flowers on a compact rounded tree that will probably never exceed 30 to 40'; the new growth emerges bronzy red; have seen this form in Spring Grove, Cincinnati, OH; flower color is much deeper than *R. hispida* and *R. fertilis*; this form flowers about 10 to 14 days earlier than 'Idaho' and over a longer period; may be the same as 'Rouge Cascade'/'Casque Rouge'; one nursery reference listed this form as seedless; have seen listed as a *R. xambigua* form; also a *R. xmargaretta* Ashe form; 'Pink Cascade' has exactly the same flower color, flowered April 24, 2005 in the Raulston Arboretum.

'Pyramidalis' ('Fastigiata')—A slender, medium-sized (40 to 50'), columnar tree with closely erect spineless branches, sparse flowers, shoots essentially unarmed, Lombardy Poplar-like in habit; utilized at Milliken Arboretum where two trees are now about 40' and have flowered more abundantly than sparsely; also have maintained the tight columnar habit.

'Semperflorens'—A large, vigorous tree which produces a major flower flush in June and a second in September or may flower continuously from midsummer on; put into commerce in 1874.

'Tortuosa'—A small tree with slightly twisted and contorted branches; the greatest concentration I have witnessed in the United States was at Cantigny Gardens, Wheaton, IL; the racemes are small and thinly set with flowers.

Twisty Baby™ ('Lace Lady', PP 9,771)—Lacy foliage, twisted shoots; does not flower; 8 to 10' high, wider at maturity; artistic form can be used for summer and winter interest in the garden; originally thought this was a small tree but observed 20 to 30' high plants; also quite fast-growing, grew 30' high at Milliken Arboretum in about 12 years; nifty architecture, especially in winter.

'Umbraculifera'—Forms a dense, umbrella-like canopy, 20' high and 20' wide, but bears few or no flowers; susceptible to borers and ice; essentially spineless; may be confused with 'Inermis' but is not the same thing; prominent in European landscapes; often used in formal avenues; effective when alive.

'Unifoliola'—The leaves are reduced to a single large leaflet or subtended by 1 or 2 normalized leaflets; I am almost positive that this form was used as a street tree in Paris but on a bus at 35 miles an hour it is hard to be absolutely sure; the single leaflet may be as long as 4" and 1 1/2" wide; it can grow 40 to 60' high.

PROPAGATION: Seed dormancy is caused by an impermeable seed coat and seeds should be scarified in sulfuric acid, soaked in hot water or mechanically scarified. Root cuttings, 1/4 to 1" diameter, 3 to 8" long, gave 25% plants; the younger the tree and roots the better. Most of the cultivars are grafted/budded.

NATIVE HABITAT: Pennsylvania to Georgia, west to Iowa, Missouri, and Oklahoma. Introduced 1635.

RELATED SPECIES AND CULTIVARS:

***Robinia hispida* L.** — Bristly or Roseacacia Locust
(rō-bin'ē-a hiss'pi-da)

LEAVES: Alternate, compound pinnate, to 9" long, 9 to 15 leaflets, elliptic to oblong-ovate or oblong, 1 to 2" long, acute to obtusish, mucronate, dark blue-green above, slightly pubescent beneath.

STEM: Rich brown, covered with hispid hairs creating a brush-like countenance.

Robinia hispida, Bristly or Roseacacia Locust, and *Robinia fertilis* (now *R. hispida* var. *fertilis* (Ashe) R.T. Clausen according to GRIN) are closely related species. *Robinia fertilis* sets fruits and seeds while *R. hispida* does not or only sparingly so. Both are small, spreading, suckering shrubs in the 6 to 10' category with prominent hispid petioles and branches. The foliage is a blue-green and the flowers rose colored or pale purple, scentless; borne in 2 to 4" long pendulous, hispid racemes; usually quite showy; flowering in late April—early May (Athens). Their cultural requirements are similar to *R. pseudoacacia*; both are good plants for stabilizing sandy banks and sterile, dry, impoverished soils. *Robinia hispida* is native from Virginia and Kentucky to Georgia and Alabama. 'Arnot' is a Soil Conservation Service selection that grows 3 to 8' high, forms dense thickets, has deep rose flowers, fixes nitrogen, and is good for stabilizing steep, sandy or gravelly slopes. 'Monument' is an old form of *R. fertilis* dating to the late 1940's when Wayside Gardens introduced it. The habit is small and compact with a narrow conical habit, flowers are rose colored, and the branches sparsely bristled, will grow 10 to 15' high, possibly a hybrid.

'Flowering Globe' is a supposed hybrid between *R. hispida* and *R. hispida* 'Macrophylla' with open, rather loose globe-headed outline, dark pink, 8 to 10" long racemes and larger leaves than the species, will grow 15 to 18' high and wide; no doubt grafted on *R. pseudoacacia* to produce a standard. *Robinia hispida* was introduced 1758. Zone 5 to 8. *Robinia fertilis* ranges from North Carolina to Georgia. Cultivated 1900. Zone 5 to 8. Current thinking merges *R. fertilis* into *R. hispida*. For all practical intents, *R. hispida* is the only species of taxonomic merit and appears in the most recent nomenclatural treatments as the correct species. In my mind, heart, and to a certain degree soul, as many "bristly" locusts as I have come across, with absolute certainty none could I positively acknowledge as *R. hispida* or *R. fertilis*. In June, 1996, Bonnie and I spied a deep rose-magenta flowered form along the highway in north Georgia. Small suckers were collected and produced 4 to 5' high plants. The flower color is the deepest and most vibrant I have observed within the genetic boundaries of the species. Also, while hiking in the north Georgia mountains, I collected another flowering variation with light lavender flowers. Grew both selections for over 10 years in the Georgia trials; the rose-magenta form garnered significant interest from visitors; unfortunately, it produced more stray (sucker) shoots than a sumac and in 2007 we were still trying to eradicate it. Not for the low-maintenance garden because it will become the garden.

***Robinia* 'Idaho'**, Idaho Locust, will grow 25 to 40' high with a spread of 15 to 30', tends to be more open than *R. pseudoacacia* in habit. Flowers are rose-pink, fragrant, 1" long, borne in 6 to 8" long, pendent racemes in May to early June. The parentage is presumably *R. pseudoacacia* and *R. hispida*. Very popular in semi-arid parts of the West that suffer extremes of heat and cold (Zone 3 and 4). Supposedly meets the stringent requirements for street tree use. Medium in growth rate. Found a tree in Urbana, IL that fit the description and, in flower, was a rather pleasing experience. Listed currently as a *R. xambigua* cultivar which means that *R. viscosa* and not *R. hispida* is the other parent.

ADDITIONAL NOTES: I am not a great fan of locust but there are situations where their use is warranted. I have observed miserable slopes along highways that were stabilized with *R. pseudoacacia* and it is doubtful that any other plant could have performed better. There are a number of southeastern United States species with pink to rose, glandular-hispid, sometimes sticky (glutinous) inflorescences that are difficult to positively identify. I attempted to make some sense of them from the Arnold Arboretum's collection during the 1991 sabbatical. Dr. Stephen Spongberg mentioned that, in essence, this is a highly confused group. The names most often listed include: *R. boyntonii* Ashe, *R. elliottii* (Chapm.) Ashe, *R. hartwegii* Koehne (now *R. viscosa* var. *hartwegii* (Koehne) Ashe), *R. kelseyi* J. F. Cowell ex Hutch. (now *R. hispida* var. *kelseyi* (J.F. Cowell ex Hutch) Isely), *R. luxurians* (Dieck) C. Schneid., *R. nana* Elliott, and *R. viscosa* Vent. Also hybrids: *R. xholdtii* Beissn. (*R. pseudoacacia* × *R. luxurians*), *R. xmarginata* Ashe (*R. hispida* × *R. pseudoacacia*), and *R. xslavini* Rehd. (*R. kelseyi* × *R. pseudoacacia*).

The above species and hybrids are listed in *The New RHS Dictionary of Gardening* and GRIN. However, one of the best field botanists in the Southeast, the late Dr. Wilbur Duncan, Emeritus Professor, University of Georgia, who has observed and collected in the wild, lists *R. pseudoacacia*, *R. hispida*, and *R. viscosa* (with sticky glands on stems, petioles, flower stalks, and fruits) as the legitimate southeastern species. *R. viscosa*, with lavender-pink-white, non-fragrant flowers in dense, 6" long racemes on May 14, 2004 at Keith Arboretum, Chapel Hill, NC. National champion 23' by 13' in Highlands, NC. Also *R. hartwegii* that, although listed as a large shrub with glandular pubescent branches, has leaflets, and pale rose-white flowers in 4 to 5" long, fattish, racemes, appearing intermediate between *R. pseudoacacia* and *R. hispida*. Fruits are also glandular-bristly. Flowered May 14, 2004 at Keith Arboretum. See *Trees of the Southeastern United States*, University of Georgia Press (1988) for specifics. Further see *Castanea* 49(4):187–202 (1984) for additional *Robinia* taxonomic information.

Rosa L. — Rose

FAMILY: Rosaceae

With each new edition, as I approach the rose revision, my mind (cluttered) and heart tell me to eliminate the entire section. The rose is a magnificent garden plant and will remain an essential element in gardens as long as there are gardens. Unfortunately, to keep them prosperous, a spray, fertilizer, and pruning regime is essential. Over the years, I have observed the University's Botanical Garden attempt to properly care for a sizable collection of Hybrid Teas, Grandifloras, and Floribundas. Some years the results were excellent; others abysmal. Mildew, black spot, and canker cause the greatest concerns but thrips, aphids, Japanese beetles, deer (yes deer), and cold contribute mightily to decline. In recent years, there has been an approach to market certain roses as "carefree" and with the Meidiland group the word rose is not used. Most interesting is the advertising campaign that describes them as "all new . . . all season, 'hybrid' flowering shrubs," with the word ROSE obvious by its absence. In about 1995, the Flower Carpet™ ('Noatrum') roses, with rose-pink and now additional flowers, were foisted upon the gardening public via massive advertising and slick marketing

campaigns. Marketing pieces touted a 2-year-old plant producing 2,000 flowers in a season, flowering up to 10 months in mild climates, evergreen to 15°F, unprecedented resistance to black spot and mildew, hardy to -20°F with no stem dieback, to -45°F with snow cover, grows 2 to 2 1/2' high and wide. Pink containers were utilized to market the rose and self-contained displays were installed in retail centers. Unfortunately, Flower Carpet™, at least in the Southeast, did not adhere to marketing hype. Black spot, sporadic flowering, and somewhat sprawley growth habit reduced it to less-than-satisfactory. Many retailers ate the plants, wholesalers had a difficult time growing plants, gardeners were disappointed, and the ROSE once again suffered unnecessary lousy press. Introductions continue and I believe will prove better than the originals.

The David Austin roses from England are immensely popular, widely advertised and promoted. I have not grown or evaluated them but do know they are susceptible to black spot and other rose maladies. Wayside Gardens, Hodges, SC, www.waysidegardens.com, and other nurseries offered extensive collections of Austin roses.

The movement toward lower maintenance roses created a frenzy of activity that could be termed "rose rustling." The plants are "rescued" from fencerows, pastures, cemeteries, and old gardens, with the concept that if they grow in such places over time then their adaptability is ironclad. Again, not so because they do contract black spot, mildew, beetles, etc., perhaps not to the degree of the modern hybrids. As I drive and jog through my beloved Georgia, I witness the roses in these habitats. At one time they were named, perhaps passed along with many name changes as they moved along the gardening path, the true name lost to antiquity. The Antique Rose Emporium, Independence and San Antonio, TX, www.antiqueroseemporium.com, has attempted to assign the correct names to many of their offerings. In many cases, a new name is assigned.

Roses tempt a gardener, not unlike candy to children (or adults). Years past I removed *all* species roses from our Georgia garden because of horrific Japanese beetle infestations and black spot. Well, a few years later I went Carefree Wonder™, Carefree Beauty™, and Carefree Delight™. Their promise was great but in Zone 7, the problems of the past surfaced. Only the first two remained and they were defoliated by July–early August, cut back in winter, and flower with unrequited love in May–June.

The only rose that appears virtually immune to black spot and other diseases in Zone 7 climate is *Rosa banksiae* 'Lutea'. Unfortunately, even this evaluation is faulty as the spring of 1998 induced terrific powdery mildew infection. Whether the species displays resistance(s) is unknown. In northern climates, *Rosa rugosa* proves the stalwart. Bonnie and I love walking the beaches of New England, from Maine to Cape Cod we have traversed and experienced this wonderful, fragrant-flowered, bright orange to red-fruited species. Certainly for a rose, it asks so little and offers so much.

Since the last edition, our Chapel Hill gardens have been graced with the Knock Out® Rose clan including original, 'Blushing Pink', 'Double Red', and 'Carefree Sunshine' (by Bill Radler, Knock Out® breeder). Remarkably great plants, particularly the original, still my favorite, as it flowers from April to November. The plant in Susy's garden is 8' by 8' after 5 years. See the section on the Knock Out® series.

A new series, the Oso Easy™ roses have been introduced by Spring Meadow Nursery. Bailey Nurseries, St. Paul, MN, has a rose breeding program and offers the Easy Elegance® series. Both series are presented in abbreviated fashion. Highly recommend checking www.springmeadownursery.com and www.baileynurseries.com. Bailey's 2009 catalog lists 145 roses, including their own introductions.

Twenty-two new rose cultivars were featured in the *American Nurseryman* 208(12) (2008) issue highlighting new plants for 2009. Four were listed as Floribunda types; four as Hybrid Teas; the rest shrub, groundcover, climber or mini.

Although the literature reports 100 to 150 (200) rose species, the interminable hybrids and cultivars escalate the numbers into the tens of thousands. Bentham and Hooker recognized about 30 species. The great Alfred Rehder, in his *Manual of Cultivated Trees and Shrubs*, which I consider the best horticultural taxonomic reference ever published, stated, "Within the limited space of this book it has not been possible to describe all the spontaneous species which could be grown within our area nor to delve deeply into the numerous horticultural forms."

To visit Sissinghurst in June when the roses are in full force in the rose garden provides the bait to entice the gardener to at least test the shrub rose waters. Perhaps what makes the Sissinghurst rose garden so unique is the inclusion of other plants, herbaceous and woody, that complement rather than compete with the shrub roses.

Also, visited Mottisfont Abbey, a National Trust property, the garden of which is dedicated largely to roses and was orchestrated by the late Graham Stewart Thomas, the great English plantsman, author, and painter. June is peak time and the fragrances, colors, and planting schemes are magnificent. The Arnold Arboretum has a wonderful species rose collection, actually with many rosaceous relatives interspersed. This also is worthy of a visit from May to the end of June. See the American Rose Society, www.ars.org, for additional information.

A final salvo: consider the numerous books on roses. Just a visit to Amazon.com offers a plethora of rose-related reading at a discount. Graham Stuart Thomas wrote *The Old Shrub Roses*, *Shrub Roses of Today*, *Climbing Roses Old and New*, *The Graham Stuart Thomas Rose Book* as well as other garden books. David Austin penned *The English Roses: Classic Favorites and New Selections*, which covers his introductions. The rose litany is fluid and forever. As long as there are gardens, roses will have a home. I was never much of a rose person for the reasons previously discussed. With the arrival of the Knock Out® series, I was converted.

Rosa multiflora Thunb. — Japanese Rose, also referred to as Multiflora Rose
(rō'za mul-ti-flō'ra)

FAMILY: Rosaceae

LEAVES: Alternate, odd-pinnate, usually 9(5 to 11) leaflets, obovate to oblong, 1/2 to 1 1/4"(2") long, acute or obtuse, serrate, pubescent, lustrous bright green, stipules with laciniate margins, glandular-bristly.

CANES: Usually with paired and occasionally scattered prickles; prickles short, recurved, more or less enlarged and flattened at base.

SIZE: 3 to 4 to 10'(15') in height and may spread 10 to 15'.

HARDINESS: Zone 5 to 8.

HABIT: A fountain with long, slender, recurving branches; eventually forming an impenetrable tangle of brush suitable only for burning.

RATE: Fast; too fast for most farmers who have this species in their fields.

TEXTURE: Medium in leaf; somewhat repulsive in winter (medium-coarse).

LEAF COLOR: Very lustrous bright green in summer; fall color, at best, is a sickly yellow.

FLOWERS: White, single, about 1" across, fragrant; June; borne in many-flowered corymbs.

FRUIT: Red, 1/4" diameter, globular to egg-shaped hip, which is effective in August and into winter.

CULTURE: Same as described under *R. rugosa* although this species is more invasive; tolerates dry, heavy soils very well.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: None in the residential landscape; has received a lot of attention for conservation purposes; makes a good place for all the "critters" to hide, yet can be a real nuisance for the birds deposit the seeds in fence rows and open areas, and soon one has a jungle; use this species with the knowledge that none of your gardening friends in the immediate vicinity will ever speak to you again.

CULTIVARS:

'Carnea'—Double pink sport of var. *cathayensis*, introduced 1804 from China.

var. *cathayensis* Rehd. & Wils.—Pale pink, 1/2 to 1"(1 1/2") diameter flowers which are borne in few- to many-flowered rather flat corymbs.

'Grevillei' ('Platypetala')—Seven sister rose; double, cerise-purple flowers, changing to mauve-pink, finally white; vigorous; free flowering; introduced from Japan about 1816.

'Inermis'—A thornless type.

PROPAGATION: Cuttings as described under *R. rugosa*. Seed should be stratified for 120 days.

ADDITIONAL NOTES: Utilized as an understock for budding the highly domesticated selections. Another species that appears resistant to black spot and the typical rose diseases. I cannot overemphasize the invasive and greedy nature of this species. Have observed entire pastures/fields invaded and captured by the plant. I have attempted to understand the species/cultivars that Bill Radler utilized to breed Knock Out®. Could this be somewhere in the parentage?

NATIVE HABITAT: Japan, Korea. Escaped from cultivation in the United States. Introduced 1868.

Rosa rugosa Thunb. — Rugosa Rose, also called Saltspray Rose, Beach Tomato, Japanese, and Ramanas Rose
(rō'za rū-gō'sa)

FAMILY: Rosaceae

LEAVES: Alternate, odd-pinnate, leaflets 5 to 9, elliptic to elliptic obovate, 1 to 2" long, acute or obtusish, serrate, lustrous, rugose, wrinkled, dark green and glabrous above, glaucescent, reticulate, and pubescent beneath, thick and firm; petiole—tomentose and bristly.

CANES: Stout, densely bristly, prickly, downy.

SIZE: 4 to 6' high by 4 to 6' wide.

HARDINESS: Zone 2 to 7(8); has been seen 100 miles from Arctic Circle in Siberia where temperature regularly falls to -50°F.

HABIT: A sturdy shrub with stout, upright stems, filling the ground and forming a dense rounded outline; suckers and forms colonies.

RATE: Fast.

TEXTURE: Medium in leaf; medium-coarse when undressed.

LEAF COLOR: Lustrous, deep rugose green in summer then briefly yellowish to bronzy and in some forms excellent orange to red.

FLOWERS: Perfect, rose-purple to white, 2 1/2 to 3 1/2" across, deliciously fragrant; June through August, often found sporadically in September and October; solitary or few in clusters.

FRUIT: Hip (for lack of better terminology), actually an urn-shaped structure (receptacle) which encloses achenes, about 1" across, lustrous orange to brick-red; maturing in summer through fall. The flowers and fruit are handsomely displayed against the dark green foliage.

CULTURE: Easy to grow, prefers well-drained soil which has been supplemented with organic matter; sunny and open; pH adaptable, however, a slightly acid soil is best; salt tolerant; possibly one of the most trouble-free roses. I have seen the species growing in pure sand not 100' from the Atlantic Ocean on Cape Cod, MA. The plant really stands out against the white sands, the dull green beach grass, and silvery wormwood (*Artemisia*). In Japan, confined to the beaches.

DISEASES AND INSECTS: Roses have about as many problems as *Prunus* and a complete listing is impossible. The most common include: black spot (a leaf disease), powdery mildew, various cankers, rusts, virus diseases, aphids, beetles, borers, leafhopper, scales, rose-slug, thrips, mites, ad infinitum.

LANDSCAPE VALUE: Rugosa Rose is a valuable plant for difficult sites: banks, cuts, fills, sandy soils, and saline environments. Very beautiful in foliage, flower and fruit. Has escaped from cultivation in the northeastern United States and is often apparent along the sandy shores of the ocean. It is also called Saltspray Rose because of its tolerance. Withstands pruning and is often used in hedges. Has been used in hybridization work because of its extreme vigor and ease of culture which would be worthwhile traits to impart to offspring. Have great affinity for this species and grew it for several years in my Georgia garden until the Japanese beetles reduced it to fodder.

CULTIVARS: Epping and Hasselkus, *American Nurseryman* 170(2):29–39 (1989), presented an excellent evaluation of *R. rugosa* and other shrub roses. Their particular focus was *R. rugosa*, hybrids and cultivars. Herein I present their observations. With over 50 cultivars in existence, they evaluated 30 of the most commonly available.

Recommended *Rosa rugosa* selections:

'Alboplana' (*R. rugosa* var. *albo-plena* Rehd.)—A selected mutation of *R. rugosa* 'Alba'. 'Alboplana' has double, pure white, fragrant flowers, dark green foliage and a dense, low habit. It grows up to 4' tall. This cultivar does not produce hips, but it is highly resistant to black spot and powdery mildew. 'Alboplana' has yellow to orange fall color and is winter hardy at -15 to -20°F . It is a good white-flowered cultivar; its only drawback is its lack of hip production.

'Belle Poitevine'—An old (1894), hybrid cultivar. It has slightly fragrant, large, semi-double, light mauve-pink flowers with showy yellow stamens. The hips are not showy, and the foliage is dull, medium green. It has yellow to orange fall color and a dense compact habit, reaching 3 1/2 to 4' tall and wide. This cultivar is highly resistant to black spot and powdery mildew and is hardy to -20°F . 'Belle Poitevine' is a tough cultivar with attractive flowers, foliage and form. Hips abscise shortly after they form.

'Blanc Double de Coubert'—Very similar to 'Alboplana', differing only in flower form and ultimate height. This hybrid has semi-double to double, pure white, fragrant flowers and showy yellow stamens. This shrub is a vigorous grower with glossy, dark green foliage, and yellow fall color. It grows 4 to 6' tall. It is highly resistant to black spot and powdery mildew and is hardy to -20°F . 'Blanc Double de Coubert' also produces fairly heavy suckers and can get somewhat leggy. References don't indicate that it is sterile, but if hips do form, they abort before becoming showy.

Rosa xcalocarpa Willm.—A hybrid *R. rugosa* $\times$ *R. chinensis* with large, single, purplish crimson, fragrant flowers and showy stamens. This 4 to 5' tall cultivar has a dense, mounded habit and excellent burnt orange to red and maroon fall color. It produces attractive, orange-red hips that are somewhat oval and sparsely punctuated with tiny spines. The leaves are dull, medium green; they are more pointed, but less rugose, than those of the species. The twigs also have a finer texture than those of the species. *Rosa xcalocarpa* is highly resistant to black spot and powdery mildew and is hardy to -20°F . Plants were attacked by mites in the dry, hot summer of 1988.

'Frau Dagmar Hastrup' ('Frau Dagmar Hartopp')—A *R. rugosa* seedling that proved to be the best all-around performer of all cultivars evaluated. It is a prolific flowerer, with fragrant, light-pink, single flowers and showy yellow stamens. This cultivar produces very large red hips in great quantity that color as early as July. They appear along with the flowers and remain showy until November. 'Frau Dagmar Hastrup' has excellent yellow to orange fall color, rich dark green foliage, and a low, dense, mounded form growing 3 to 4' tall. It has the greatest resistance to black spot and powdery mildew of any *R. rugosa* cultivar evaluated. It is very hardy with no winter injury at -21°F . This is one of my all time favorite roses. The flowers, fruits, and foliage are almost prescription perfect.

Acceptable cultivars:

'Delicata'—An old (1898), hybrid cultivar with large, semi-double, lilac-pink, slightly fragrant flowers and showy yellow stamens. The large orange-red hips are sparsely produced and sometimes occur with the flowers. The dark green foliage turns yellow in fall. 'Delicata' is a vigorous grower with a good, dense form (3 to 4' tall) and is winter hardy at -21°F . It is not as disease-resistant as 'Belle Poitevine', but it is useful when a darker pink flower is preferred. 'Delicata' was moderately infected with black spot in late August and September 1987 but was disease-free during the drier 1988 growing season.

'Hansa'—A hybrid cultivar with semi-double, large, purplish red, very fragrant flowers. It produces many orange-red hips, often along with the flowers. This cultivar has dark green, glossy, black spot-resistant foliage and yellow to orange fall color. The upright habit is often tall and leggy, and this shrub grows to an ultimate height of 5 to 6'. Winter injury was not observed at -21°F and 'Hansa' is a good performer except for its leggy habit. This cultivar and 'Delicata' are rather similar, but 'Delicata' has lighter pink flowers and a better compact habit. 'Hansa' has a superior hip display and is more resistant to black spot.

'Scabrosa'—A rather recent (1950) hybrid introduction. Its large, single, deep mauve-pink flowers have showy yellow stamens and usually appear in clusters of five. 'Scabrosa' produced attractive flowers and fruit, but not as freely as 'Frau Dagmar Hastrup'. The large, orange-red hips are abundant, and the bright green foliage is resistant to black spot and powdery mildew. 'Scabrosa' has yellow to orange fall color and a dense, low, mounded form. It grows 3 to 4' tall. This cultivar is very hardy.

'Schneezwerg' ('Snowdwarf')—A floriferous hybrid with semi-double, small, white flowers and showy yellow stamens. Small, orange-red, showy hips often appear with the flowers. The dark green foliage has a finer texture than that of *R. rugosa* but is somewhat susceptible to black spot. 'Schneezwerg' has a mounded, dense habit and ultimately grows 4 to 5' tall and wide. This cultivar is winter hardy to -20°F .

'Thérèse Bugnet'—A hybrid cultivar with large, double, medium pink, loosely clustered and very fragrant flowers. The red hips are rare, and the blue-green foliage is slightly susceptible to black spot and turns yellow and orange in fall. The attractive, glossy red canes are somewhat susceptible to rose stem girdler attacks. The upright habit suckers to form dense thickets, and this shrub grows 5 to 6' tall. 'Thérèse Bugnet' is very attractive in the winter landscape due to its shiny red canes and is winter hardy to -20°F . Its biggest drawback is its susceptibility to rose stem girdler. This is not surprising since *R. acicularis* Lindl., one of its parents, can be extremely susceptible to this insect.

Further Evaluation Needed:

'Dart's Dash'—Has large, semi-double, mauve flowers and large, orange-red hips. The foliage is bright green and showed no sign of disease.

'Roseraie de l'Hay'—A cultivar of a sport of *R. rugosa* 'Rosea'. It has large, double, crimson-purple and very fragrant flowers. The sparse hips are not showy. No black spot, powdery mildew or other diseases on the light green foliage was evident. Krüssmann says this cultivar has a bushy form and reaches medium height. The cultivar is listed as hardy in Zone 2.

'Topaz Jewel'—A recent hybrid cultivar and one of the few yellow-flowered *Rugosa* Roses. It is a recurrent flowerer with semi-double, light yellow flowers and showy orange stamens. No hip production was noticed. The medium green foliage had no evidence of black spot or other diseases. 'Topaz Jewel' is described as having a dense, bushy habit with arching canes. It grows up to 5' high and 7' wide.

Cultivars not recommended: Rather than describing attributes and liabilities, I chose to simply list those deemed unacceptable by Epping and Hasselkus. The reader may consult the original article for specifics. 'Agnes'; 'Alba'; 'Charles Albanel' (Explorer, Canada); 'David Thompson' (Explorer, Canada); 'Dr. Eckener'; 'F. J. Grootendorst'; 'Flamingo'; 'Grootendorst Supreme'; 'Henry Hudson' (Explorer, Canada); 'Jens Munk' (single, fragrant, medium pink, magnificent when viewed by this author, Explorer, Canada); 'Martin Frøbisher' (Explorer, Canada); 'Mrs. Anthony Waterer'; 'Pink Grootendorst'; 'Sarah van Fleet'; 'Schneckoppe' (pink buds open to fragrant, double, white flowers with lavender suffusion, dwarf, bushy, 3'); 'Sir Thomas Lipton'; 'The Hunter' (double, fragrant, brilliant red, repeat flowering); 'White Grootendorst'.

PROPAGATION: The seeds (actually achenes) of most species exhibit dormancy which is principally due to seedcoat conditions rather than embryo dormancy. Cold stratification at 40°F for 90 to 120 days is recommended for *R. rugosa*. Plant Introductions, Inc. has been doing rose seed germination and has had great success with 3 months warm/3 months cold stratification. Seeds are germinating like green beans from this treatment. Cuttings can be effective with the species roses. Hardwood cuttings should be taken

from November through early March, stored in sand or peat at 35 to 40°F and planted outside in spring, with only about 1" of the upper end of the cutting protruding. Softwood cuttings should be taken in July, August, and September with all but the top leaf removed. Rose cuttings respond to IBA and 1,000 ppm IBA talc or quick dip is recommended. KIBA is superior to alcohol solutions.

ADDITIONAL NOTES: The species roses of which *R. rugosa* is a member, are not as prone to the diseases and insects as the hybrid types. They are more vigorous and less exacting as to culture. The fruits of *R. rugosa* are supposed to make the finest jelly.

NATIVE HABITAT: Northern China, Korea, Japan. Introduced 1845. Creech, *American Nurseryman* 160(6): 77–79 (1984), says introduced around 1770.

OTHER SPECIES ROSES

Rosa banksiae W.T. Aiton 'Lutea' — Lady Banks' Rose
(rō'za bank'si-a)

LEAVES: Alternate, compound pinnate, evergreen, elliptic-ovate to oblong-lanceolate, 3 to 5 leaflets, rarely 7, 1 to 2 1/2" long, acute or obtusish, serrulate, glabrous except at base of midrib below, lustrous dark green; rachis pubescent.

STEM: Lustrous green, glabrous, thornless.

Rosa banksiae 'Lutea' is a common occurrence in southern gardens especially those with period (1850 to 1900) connotations. The species is a sprawling climber (15 to 20') that requires restraint to be kept in bounds. Have seen plants in England over 30' high. The stems are nearly (in most cases completely) thornless. Used a great deal on fences, trellises, and also espaliered against walls. The flowers are white or yellow, 1" across, slightly fragrant, on smooth stalks in many-flowered umbels from April into June. Flowering occurs in late March to mid-April in Athens and seldom disappoints. The double-flowered, slightly fragrant, yellow cultivar, 'Lutea', is the common representative of this species in southern gardens and is also called "Lady Banks' Rose". 'Alba Plena' ('Alboplena') double, white, fragrant; 'Lutescens' single yellow, sweetly fragrant; 'Normalis' (var. *normalis* Regel) has single, white, sweetly fragrant flowers; 'Snowflake' bears single, white flowers, climbs to 20', suspect it is a popular name for 'Normalis'. The plant requires no special insect and disease control measures and actually appears to thrive with neglect. Mildew was severe in Athens. Tolerates a modicum of salt spray. Withstands full sun and partial shade. Roots readily from softwood cuttings. China. Zone 7 to 8.

Rosa blanda Ait. — Meadow Rose
(rō'za blan'da)

LEAVES: Alternate, compound pinnate, 5 to 7 leaflets, rarely 9, elliptic to obovate-oblong, 1 to 2 1/2" long, acute, coarsely serrate, dull blue-green above, glabrous, paler and finely pubescent or glabrous below; stipules dilated.

CANES: Sparsely thorned or with scattered bristles to thornless with attractive red bark.

HABIT: Dense, mounded, strong growing, suckering, 4 to 5' high.

FLOWERS: Single, light pink, fragrant, 2 to 3" across, solitary or few together, May–June.

FRUIT: Subglobose to ellipsoidal, 1/2" diameter, smooth bright red hips that color in late July and remain showy into winter.

ADDITIONAL NOTES: Epping and Hasselkus rated it one of the best roses for fruit display. Their only objection was late season black spot susceptibility.

NATIVE HABITAT: Newfoundland to Pennsylvania, Missouri, North Dakota and Manitoba. Introduced 1773. Zone 2 to 6(7).

Rosa carolina L. — Carolina Rose, Pasture Rose

(rō'za ka-rō-lī'na)

LEAVES: Alternate, pinnately compound, leaflets usually 5, rarely 7 to 9, elliptic to lance-elliptic, rarely oblanceolate, 1/2 to 1 1/4" long, acute or obtuse, sharply serrate with ascending teeth, shiny rich green, glabrous beneath, pubescent on veins or nearly glabrous, stipules narrow; in autumn the leaves turn a dull red of varying shades.

CANES: Often covered with scattered and paired prickles and bristles when young, sometimes rather sparsely so later; prickles slender, usually not flattened except on vigorous branches, mostly straight.

HABIT: 3 to 6' high, freely suckering shrub composed of erect branches forming dense thickets.

FLOWERS: Pink, single, fragrant, 2 to 2 1/2" across, solitary or 2 to 3 together, June into July (August). Variety *alba* Raf. has white flowers.

FRUIT: Red, 1/3" diameter, urn- or pear-shaped, glandular-hairy, persisting into winter and maintaining good color.

ADDITIONAL NOTES: Encountered the species in Maine in late summer where a few flowers were still emerging. More petal color variation than literature affords from light to deep, almost rose, pink.

NATIVE HABITAT: Maine to Wisconsin, Kansas, Texas and Florida. Introduced 1826. Zone 4 to 9. Common in low wet grounds and borders of swamps and streams.

Rosa chinensis Jacq. — China Rose, Bengal Rose

(rō'za chi-nen'sis)

LEAVES: Alternate, compound pinnate, 3 to 5 leaflets, 1 to 2 1/4" long, lanceolate to broad-ovate, acuminate, serrate, glossy green, glabrous above, pubescent on midrib below.

CANES: Green-red, glabrous, with scattered, slightly hooked, extremely sharp prickles.

HABIT: Shrub 6 to 8' high and as wide, semi-climbing to 20'; in cultivation ('Mutabilis') typically a 5 to 6' tall shrub.

FLOWERS: Single or semi-double in the species, crimson, pink, occasionally white, usually fragrant, solitary or in multiples, 2" diameter, flowering from April (Athens) to late summer (if foliage still present).

FRUIT: Ovoid to pear-shaped, 1/2 to 3/4" long, green-brown to scarlet; I have not observed fruits on 'Mutabilis'.

CULTIVARS: Several but 'Mutabilis' (considered a cultivar *R. xodorata* (Andr.) Sweet; *R. chinensis* × *R. gigantea*) grows 5 to 6' high and wide, new leaves bronze-purple, finally blue-green, single, fragrant, 1 to 2 1/2"(3") diameter, flowers change from yellow-orange (sulfur yellow), coppery salmon pink to deep pink, cultivated 1934, terrific plant for flower effect, unfortunately susceptible to black spot, the more leaves the greater the flower production, still one of the better roses for unbridled use in Zones 7 and 8.

ADDITIONAL NOTES: Utilized to produce repeat flowering in European roses when it was introduced around 1800. Considered the ancestor of the modern garden hybrids.

NATIVE HABITAT: China. Known only from gardens. Cultivated 1768.

Rosa foetida Herrm. — Austrian Brier Rose, Austrian Yellow Rose

(rō'za fet'i-da)

LEAVES: Alternate, pinnately compound, 5, 7, or 9 leaflets, oval or obovate, 3/4 to 1 1/2" long, rounded or broad cuneate, edged with a few glandular teeth, brilliant parsley green and glabrous or with scattered hairs above, glandular and more or less downy below.

CANES: Grayish to chestnut brown, furnished with many slender, straight or slightly curved prickles abruptly widened at base and up to 3/8" long.

HABIT: Rather lax, with erect-arching canes, 6 to 7' high.

FLOWERS: Deep yellow, 2 to 3" across, usually solitary, or 2 to 4 together, May–June.

FRUIT: Rarely seen in cultivation, listed as globose to spherical, smooth or bristly, red, 1/2" wide.

CULTIVARS:

'Bicolor' (Austrian Copper)—A magnificent rose with copper-red petals, yellow on the back side; often yellow or combination colored flowers occur on some branches; it is a tremendous experience to see it in full flower, perhaps no more handsome rose; black spot susceptible.

'Persiana'—Double, yellow flowers which are freely borne.

NATIVE HABITAT: Western Asia. Introduced before 1600. Have read before 1542. Zone 4 to 7. Has performed well in the University's Botanical Garden. Susceptible to black spot. Species and cultivars utilized in the breeding of modern garden roses. My understanding is that almost any hybrid with *R. foetida* ancestry is black spot susceptible.

Rosa glauca Pourr. (*R. rubrifolia* Villars) — Redleaf Rose

(rō'za glaw'ka)

LEAVES: Alternate, pinnately compound, 5 to 7(9) leaflets, ovate or elliptic, 1 to 1 1/2" long, toothed, glabrous, of a beautiful coppery or purplish hue, and covered with a dull waxy bloom.

CANES: Covered with a purplish bloom, armed with small decurved prickles; strong canes clad with bristles and needles.

HABIT: A 5 to 7'(10') high, erect-caned, eventually arching-spreading shrub of good density, with time will become leggy at the base.

FLOWERS: Clear pink, single, 1 1/2" wide, solitary or in multiples, May–June, not effective especially against the reddish foliage backdrop.

FRUIT: Ovoid to subglobose, red to brown, 1/2" long, usually smooth or with small bristles.

ADDITIONAL NOTES: A fine addition to any shrub border because of interesting foliage color. It can be used in groups where it makes a great show. Interestingly, I have read descriptions of the flowers which state bright red but the plants I have seen were pink flowered. Abundant variation in flower color from seed grown specimens. I have grown a number of seedlings to flowering size and witnessed light pink to deep pink flowers. Susceptible to foliar diseases and I have observed plants with essentially no foliage in late summer; others heavily foliated.

NATIVE HABITAT: Mountains of central and southern Europe. Introduced 1814. Zone 2 to 7.

Rosa ×harisonii Rivers—Harison's Yellow Rose

(rō'za hār-i-sō'nē-ī)

LEAVES: Alternate, pinnately compound, 5 to 9 leaflets, elliptic, glandular below, margins with compound, somewhat glandular teeth.

HABIT: Upright shrub growing 4 to 6' high.

FLOWERS: Yellow, double, about 2" diameter, borne over a two week period in early June; very dependable flowering shrub; has a somewhat unpleasant odor.

FRUIT: Nearly black, small, bristly, not ornamentally effective.

ADDITIONAL NOTES: The specific epithet is occasionally spelled *harrisoni*. A hybrid between *R. foetida* × *R. pimpinellifolia* (now *R. spinosissima* L.). Raised by George Harison of New York in 1830. Zone (4)5 to 7. A cultivar name is given to this form—'Harison's Yellow'.

Rosa laevigata Michx. — Cherokee Rose

(rō'za lē-vi-gā'ta)

LEAVES: Alternate, pinnately compound, evergreen to semi-evergreen, trifoliate or with 5 leaflets, elliptic or ovate, 1 1/2 to 4" long, half as wide, of thick, firm-texture, toothed, lustrous dark green, glabrous.

CANES: Armed with hooked, red-brown prickles, sometimes mixed with bristles on the branchlets.

HABIT: Spreading, arching, tangled, 8 to 10' high shrub which will climb over and through trees; one plant on the Georgia campus was about 8 to 10' high and 15 to 18' wide and literally impenetrable; have seen plants on Georgia's Jekyll Island climbing over shrubs and through tree branches; canes may extend 30' and greater.

FLOWERS: Pure white, fragrant, solitary, 3 to 4" across, beautiful in flower, April–May.

FRUIT: Red, thickly set with bristles, pyriform, 1 1/2 to 1 3/4" long, 3/4" wide.

ADDITIONAL NOTES: The state flower of Georgia. It is a beautiful plant but with all the magnificent native plants in Georgia it seems strange that this would be chosen. Was cultivated about 1780 in Georgia. Not particularly cold hardy as -3°F in Athens killed the above described plant outright. A pink-flowered form ('Anemone') is available but is probably a hybrid. I grew it for a year and removed the plant because of rampant growth and vicious prickles. Flowers are beautiful. Am not absolute about degree of invasiveness but have observed runaway plants on Jekyll Island.

NATIVE HABITAT: Southern China, Taiwan, extending into Myanmar (Burma). Zone 7 to 9. Naturalized from Georgia to Florida to Texas.

Rosa luciae Franch. & Rochebr. ex Crép. (formerly *R. wichuraiana* Crép.) — Memorial Rose, Sunshine Rose

(rō'za lū'sē-ā)

LEAVES: Alternate, evergreen to semi-evergreen, pinnately compound, 7 to 9 leaflets, suborbicular to broad-ovate or obovate, 1/2 to 1" long, usually obtuse, coarsely serrate, lustrous dark green above and beneath, glabrous, stipules dentate.

CANES: With scattered prickles; prickles sparse, strong, and recurved.

HABIT: A procumbent shrub, of semi-evergreen nature, with long, green canes trailing over the ground and rooting; will climb if supported. Probably stays in the 8 to 16' category from a width aspect.

FLOWERS: Pure white with rich yellow stamens in the center, fragrant, single, about 2" across, borne in few- to many-flowered pyramidal corymbs in June and July.

FRUIT: Red, about 1/2" long, egg-shaped; maturing in September–October.

ADDITIONAL NOTES: This species makes an excellent ground cover. I have seen it used on highway slopes where it does an excellent job of holding the soil as well as adding a touch of beauty. Has been used in breeding work and is a parent of many of the modern climbers. Good plant because of its ease of culture and freedom from insects and diseases.

NATIVE HABITAT: Japan, Korea, Taiwan, Eastern China. Found on beaches and low hills along the coast in southern parts of Japan. Introduced in 1891 into North America by the Arnold Arboretum. Zone 5 to 8.

Rosa moyesii Hemsl. & Wils. — Moyes Rose

(rō'za moy-es'ē-ī)

LEAVES: Alternate, pinnately compound, 3 to 6" long, 7 to 13 leaflets, ovate to roundish oval, 3/4 to 1 1/2" long, singly or doubly toothed, glabrous except on midrib below which is downy and sometimes prickly, dark green above, pale or glaucous beneath; petiole—glandular, sticky.

CANES: Erect, armed with stout, pale, scattered, broad-based prickles, abundant on non-flowering shoots, the lower part being furnished with fine needle-like prickles; flowering shoots less prickly.

HABIT: Medium-size to large, erect branched shrub of sturdy habit; grows 6 to 10' high and wide.

FLOWERS: Intense blood red, 2 to 2 1/2" across, solitary or in pairs, June–July.

FRUIT: Red, 1 1/2 to 2 1/2" long, bottle-shaped, crowned by the erect persistent sepals, glandular hairy.

ADDITIONAL NOTES: Popular species rose, and the parent of several hybrids. Beautiful in flower and fruit.

'Geranium'—A compact, bushy form with lighter green foliage and clear geranium red flowers; have seen frequently in English gardens, beautiful flower; considered a hybrid, slightly more compact than species, fruits (red) larger and smoother. Raised at Wisley in 1938.

NATIVE HABITAT: Western China. Introduced 1894 and 1903. Zone 5 to 7.

Rosa palustris Marsh. — Swamp Rose

(rō'za pal-us'tris)

LEAVES: Alternate, compound pinnate, 7 to 9 leaflets, elliptic to narrow-oblong, acute, 1 to 2" long, finely serrate, glossy dark green, usually pubescent below, stipules narrow, rolled inward.

CANES: Slender, glabrous, reddish stems.

HABIT: Shrub, 3 to 6' high.

FLOWERS: Pink, fragrant, about 2" across, in corymbs, subtended by leafy bracts, pedicels short, glandular-hispid, June–August.

FRUIT: Red, about 1/3" long, late summer–fall into winter.

NATIVE HABITAT: Nova Scotia, Minnesota, Mississippi and Florida. Introduced 1728. Zone 4 to 9. Observed in swamp, in flower, July 8, 2007, Highlands Botanical Garden.

Rosa sericea Lindl. ssp. *omeiensis* (Rolfe) A.V. Roberts (formerly *R. omeiensis* Rolfe) — Omei Rose

(rō'za se-ri'sē-a ō-mī-en'sis)

LEAVES: Alternate, pinnately compound, usually 5 to 9(11) leaflets, oblong or elliptic-oblong, 1/2 to 1 1/2" long, acutish, cuneate, serrate, rich green, glabrous, puberulous on midrib beneath; petiole—puberulous and prickly.

HABIT: Large spreading shrub with rich green, finely divided leaflets which give the plant a fern-like appearance. Can grow 10 to 15' high and wide.

FLOWERS: White, single, 1 to 2 1/2" across, June, not overwhelmingly effective.

FRUIT: Pear-shaped, 1/3 to 2/3" long, glossy orange-red; borne on yellow stalks, maturing in July–August, falling soon after maturation.

ADDITIONAL NOTES: Fruits are especially beautiful as are the large, broad-based, translucent, ruby red prickles that provide winter interest and make for interesting flower arranging effects. 'Chyrsocarpa' (var. *chyrsocarpa* Rehd., f. Fr.) has yellow fruits. Forma *pteracantha* Franch. has much enlarged reddish prickles often forming wide wings along the stem, reddish.

NATIVE HABITAT: Western China. Introduced 1901. Zone 4 to 7.

Rosa setigera Michx. — Prairie Rose, also called Michigan Rose or Climbing Rose

(rō'za se-tij'ēr-a)

LEAVES: Alternate, pinnately compound, leaflets 3, rarely 5, ovate to oblong-ovate, 1 1/4 to 3 1/2" long, short-acuminate, serrate, pubescent on veins beneath; lustrous dark green in summer; fall colors often a combination of bronze-purple, red, pink, orange and yellow.

CANES: With scattered or paired prickles; prickles strong, usually recurved, enlarged and flattened at base; stems, petioles and peduncles often glandular-pubescent; stems green or reddish, often dark purple with a bloom.

HABIT: A wide-spreading shrub with arching and spreading canes which may extend 15' in a single season. May grow to 15' but usually shorter; when climbing over flat ground grows 3 to 4' in height.

FLOWERS: Deep pink fading to white, nearly scentless, single, about 2" across; borne in few-flowered corymbs in late June through early July.

FRUIT: Red to greenish brown, globular, 1/3" diameter, glandular bristly, maturing in fall.

ADDITIONAL NOTES: One of the latest flowering species roses. Quite hardy (Zone 4) and has been used in breeding work. Might be a good plant for difficult areas along highways; definitely not for the small garden.

NATIVE HABITAT: Ontario to Nebraska, Texas and Florida. Introduced 1810.

Rosa spinosissima L. — Scotch Rose (formerly *R. pimpinellifolia* L.)

(rō'za spī-nō-sis'i-ma)

LEAVES: Alternate, pinnately compound, 5 to 11 leaflets, usually 7 to 9, orbicular to oblong-ovate, 1/2 to 1" long, simple serrate, or doubly glandular-serrate, lustrous bright green, glabrous, sometimes glandular beneath; stipules entire, rarely glandular-dentate.

CANES: Densely covered with straight, needle-like bristles and prickles.

HABIT: A dense, free-suckering shrub of mound-like, symmetrical habit, often forming thickets; may grow 3 to 4' high.

FLOWERS: Pink, white, solitary, single, but numerous on short branches along the stems, 1 to 2" diameter; May–early June.

FRUIT: Black or dark brown, 1/2 to 3/4" diameter, smooth, glabrous; effective in September.

ADDITIONAL NOTES: One of the most widely distributed rose species.

Very variable and numerous cultivars are known. Assets include low habit, profuse flowering, variation in flower color, size, doubleness; also of easy culture. Common shrub of coastal sand dunes in its native range. A selection of unknown origin 'Petite Pink' was named by the JC Raulston Arboretum and heavily promoted. Many growers carried the banner and produced thousands. Unfortunately, in Zone 7, it is terrifically susceptible to mites and does not flower reliably; in actuality should be on the discard pile; flowered May 30, 2005 at Raulston, the best show of double pink, 1 1/2" diameter flowers I ever witnessed.

NATIVE HABITAT: Europe, western Asia, naturalized in northeastern United States. Cultivated before 1600. Zone 4 to 8.

*Rosa virginiana* Mill. — Virginia Rose

(rō'za vēr-jin-ē-ā'na)

LEAVES: Alternate, pinnately compound, 7 to 9 leaflets, elliptic to obovate, 1 to 2 1/2" long, usually acute at ends, serrate with ascending teeth, glossy dark green; upper stipules dilated.

CANES: Reddish, with mainly paired prickles, sometimes variously prickly or bristly; prickles thick-based, flattened, straight or often hooked.

HABIT: A low to medium-sized shrub which often forms a dense, suckering mass of erect stems. Will grow 4 to 6' in height.

FLOWERS: Pink, single, fragrant, solitary or 2 to 3 together, 2 to 2 1/2" across; June (May 25, 1991 at Arnold Arboretum), sporadically into late summer.

FRUIT: Red, subglobose, about 1/2" diameter, smooth or glandular bristly, ripening late and persistent through winter.

ADDITIONAL NOTES: One of the more handsome native roses. The summer foliage is excellent glossy dark green and changes first to purple then orange-red, crimson and yellow in autumn. The fruits are a bright glistening red and persist into winter. The canes are reddish with many paired prickles and are attractive. Can be used as an effective barrier or low hedge, and when it has overstepped boundaries it can be cut to the ground and will develop quickly to excellent form. Excellent in sandy soils, particularly by the sea.

NATIVE HABITAT: Newfoundland to Virginia, Alabama and Missouri. Introduced before 1807. Zone 3 to 7(8).

Rosa xanthina Lindl. forma *hugonis* (Hemsl.) A.V. Roberts (formerly *R. hugonis* Hemsl.) —
 Father Hugo Rose
 (rō'za zan-thī'na hū-gō'nīs)

LEAVES: Alternate, pinnately compound, 5 to 13 leaflets, oval to obovate or elliptic, fresh green, 1/4 to 1" long, obtuse, sometimes acutish, finely serrate, glabrous, or slightly villose on the veins when unfolding.

CANES: Often reddish, with scattered prickles, usually also bristly at least at base of non-flowering young growth; prickles stout, straight, flattened, often red.

HABIT: Medium-sized (6 to 8') shrub with upright arching canes and a twiggy rounded habit; often broader than high.

FLOWERS: Single, canary yellow, 2 to 2 1/2" diameter, solitary, May–June; beautiful in flower as each branch is covered with rich yellow flowers.

FRUIT: Scarlet turning blackish red, nearly globular, about 1/2" across, ripening in August.

ADDITIONAL NOTES: One of the more common species roses; often found in older gardens. Good, free flowering, bright yellow shrub. Looks a little ragged when not in flower.

NATIVE HABITAT: Central China. Introduced 1899. Zone 5 to 8.

LOWER MAINTENANCE ROSES

Carefree Beauty™ ('Beubi')—Becoming more common in gardens; in Wisconsin tests, it produced semi-double, fragrant, medium pink flowers from June to frost; the hips remained green; foliage is thickish, glossy medium green and does not develop fall color; resistant to black spot and powdery mildew; habit is somewhat open, 3 to 4' high and wide; hardiness response was akin to 'Bonica'; the cultivar has been included in the Dirr garden and is beautiful in flower but covered with black spot by summer.

Carefree Wonder™—Upright shrubby vigorous form, not too different from Carefree Beauty™; produces rich pink, double (semi-double) flowers in great profusion in April and May, sporadically in summer into fall; have photographed the last "rose of summer" in late October; unfortunately, Carefree Wonder™ and Carefree Beauty™ side-by-side in the Dirr garden are often defoliated by late July–August; as temperatures cool new growth develops and flowers are produced; grows 3 to 5' high in a single season; I cut the prominently prickled stems to 12 to 18" of the ground in late winter; terrific bud and flower set on new growth flush of season.

'Chuckles'—Lovely mounded form with deep rose-pink, 2" diameter, single flowers, glossy green foliage, flowers continuously on new growth, 2 to 3' by 2 to 3', moderate disease resistance.

'The Fairy'—One of the roses I regret having never tested; abundant in New England, seemingly in gardens all along the coast; soft pink, double flowers are produced in profusion and literally enshroud the glossy green foliage during June–July; plant habit is spreading, almost ground cover-like, 2 to 3'(4') by 2 to 3'(4'); foliage displays reasonable disease resistance, will contract black spot.

Ferdy™ ('Keitoli', PP 5,841)—Produces profuse coral-pink, 1 to 1 1/2" diameter, double flowers over a 4 week period in spring; flowers so heavily that the glossy medium green foliage is almost obscured, in fall the leaves turn shades of red; grows 3 1/2 to 5' by 3 to 4' with a graceful cascading effect; Zone 4.

Home Run™ ('Wekcibako', PP 18,552)—Single, saturated, geranium-red, 3" diameter flowers; dark green foliage; good disease resistance; appears slower growing than Knock Out®; grows across the fence in our neighbor's garden and simply can't compete with Knock Out®; have heard that Knock Out® is in the parentage; estimate 3 to 5' high and wide; from Weeks Roses, CA.

'Living Easy'—Beautiful, salmon-orange-red, double flowers; shiny green foliage; 4 to 6' height; looked like a winner early in Georgia trials but black spot proved troublesome.

'Nearly Wild'—Excellent spreading shrub form, 2 1/2' by 4', often taller and wider, with 1 1/2 to 2" diameter, rich pink, single flowers and grading to white at the petal base; excellent plant for massing; reasonable disease resistance based on my Arnold Arboretum observations, will contract black spot but maintains sufficient foliage to keep trucking; flowering in late September in Dirr Chapel Hill garden; grows larger than stated to 4 to 5' high, wider at maturity; still a good choice but being supplanted by Knock Out® series.

'Seafoam'—Another time-tested rose like 'The Fairy' and widely available in commerce; cream-white, fragrant, double flowers are borne in profusion during June; glossy foliage, reasonable disease resistance; vigorous, spreading habit, 2 to 3' by 5 to 6'.

MEIDILAND SERIES

The name rose conjures maintenance and Conard-Pyle, West Grove, PA, the introducer of the Meidiland series in the United States wanted to avoid the connotation. The jury is still out on their absolute carefree nature but to date the reports have been favorable. They are definitely black spot and mildew resistant. However, early spring and midsummer fungicide applications are recommended. In my Georgia trials, Scarlet Meidiland™ and White Meidiland™ fared the best. All contracted some black spot.

Alba Meidiland™ ('Meiflopan', PP 6,891)—White, double flowers, red fruits, deep green foliage, yellow in fall, mounded-spreading, 2 1/2' by 6'.

Bonica™ ('Meidomonac', PP 5,105)—The first in the series with medium pink buds that open to pastel pink, fully double (50 petals), 3" wide flowers; considered everflowering with cycle highest in spring and late summer-fall; produces bright orange-red hips (remained green in Madison, WI); upright, arching habit, 5' by 4 1/2' to 5'; small glossy dark green leaves do not develop fall color; hardy to Zone 4 to 5; in Wisconsin tests -12°F caused tip die back of at least 12"; -21°F killed plants to the ground but they did resprout to 3' and flower by mid-June; black spot (heavy) September 11, 2004, Blue Hill, ME.

Carefree Delight® ('Meipotal', PP 8,841)—Single, deep pink flowers; glossy dark green foliage; low-mounding habit, 2 1/2' by 4'; flowers on new growth, will flower to some degree into fall; tested in Dirr garden for one growing season and became so disease ridden it was removed, reported to have foliar resistance, possibly better in Zone 4 and 5 than 7.

Carefree Spirit™ ('Meizma', PPAF)—Cherry-red flowers with white eyes; 15 to 20 on each shoot, continuous flowering; high resistance to black spot, totally resistant to mildew and rust; bushy, mounding habit; 5' by 4 to 5 1/2'; Meidiland International hybrid, Conard-Pyle introduction; named 2009 AARS winner.

Fuchsia Meidiland™ ('Meipelta', PP 8,839)—Mauve-pink, 2" diameter, double flowers, red fruits, ground cover form, 2 1/2' by 4 1/2'.

Pearl Meidiland™ ('Meiplatin', PP 6,807)—Ivory pink, double flowers, ground cover habit, deep green foliage, 2 1/2' by 6'.

Pink Meidiland™ ('Meipoque', PP 5,956)—Represents a more upright form, 3 to 4' by 1 1/2' to 2 1/2', that can be used as a buffer, mass or unpruned hedge; the single, 2 to 2 1/2" diameter pink with white center flowers open from spring to frost and are followed by reddish fruits that provide winter interest; foliage is slightly glossy medium green and densely borne; Zone 4 to 5.

Red Meidiland™ ('Meineble', PP 7,116)—Handsome low-growing form with single, red flowers, white center, yellow stamens; 1 to 1 1/2' high, 4 to 5' wide; produces orange-red fruits.

Scarlet Meidiland™ ('Meikrotal', PP 6,087)—Double, 1 to 1 1/2" diameter, scarlet flowers occur in profusion for 4 weeks in early summer and sporadically until frost; grows 3 to 4' by 5 to 6' and makes an excellent cover; abundant glossy rich green foliage adds to the plant's aesthetic qualities; black spot susceptible but relatively clean on October 15, 2004 in Cincinnati; Zone 4 to 5.

White Meidiland™ ('Meicoublan', PP 6,088)—Was prospering in the University's Botanical Garden tests until the deer reduced it to rubble; a low-growing almost ground cover type with dense, lustrous, leathery dark green leaves and up to 4" wide, double pure white flowers from June into fall; will grow 1 1/2 to 2' high by 4 to 5' wide; makes a good mass or ground cover; Zone 5.

EXPLORER SERIES

For years Agricultural Canada has introduced cold hardy, disease-free roses for Canada and the northern United States. As long as I can remember Felicitas Svejda had her name attached to many (perhaps all?) of the new introductions. The introductions were tested at several locations in Canada and the northern United States over a number of years to assess floriferousness, hardiness and disease resistance. They are called the Explorer Series and are named accordingly. Many have *R. rugosa* in their parentage. I have added cultivars not included in the 1998 edition or designated them as Explorer types under *R. rugosa* (which see). May experience stem dieback in extremely cold winters, -25 to -35°F, but will flower on regrowth of season. Although these roses were bred for cold hardiness and disease resistance for the harsh climates of Canada and the northern United States, they did not prove particularly worthy in Epping and Hasselkus' trials in Madison, WI. See *Horticulture* 70(2):26-32 (1992) for "Roses from the North."

'Alexander MacKenzie'—Red, 10 petals, high disease resistance.

'Champlain'—Combines winter hardiness with the flowering habit and attractive flowers of Floribunda Roses; grows 3' high with 2 to 2 3/4" diameter, 30-petaled, dark red, fragrant flowers; leaves are abundant, lustrous and dark yellow-green, medium disease resistance; riddled with black spot, September 8, 2004, Falmouth, ME.

'Charles Albanel'—Derived from 3 cycles of open pollination of *R. rugosa* 'Souvenir de Philemon Cochet'; grows 3' by 3 1/2'; flowers are 3 to 4" diameter, 20-petaled, fragrant, medium red; the leaves are rugose dark green and abundant; stems are prickly and bristly; high black spot and mildew resistance;

- long flowering period, fragrance and vigor are principal attributes; interestingly, Epping and Hasselkus found this selection unacceptable.
- 'David Thompson'—Red, double, 32 petals, 2 3/4" diameter, fragrant, recurrent flowers, 3 to 4' high, derived from 'Schneezweg' × 'Frau Dagmar Hastrup', high disease resistance.
- 'De Montarville'—Dieback shrub producing red-pink, mottled pink buds that open pink; glossy leaves; powdery mildew resistance, tolerant of black spot.
- 'Henry Kelsey'—Red, 25 petals, climber, medium disease resistance.
- 'John Cabot'—Medium red, 30 petals, climber, high disease resistance.
- 'John Davis'—A trailing growth habit to 6 to 8' long, medium pink, perfume fragrance, 3 to 4" diameter, 40-petaled flowers occur in clusters of approximately 17; unopened bud is bright red and unfurls to pink; leaves are leathery, glossy dark green, resistant to black spot.
- 'John Franklin'—Red, 25 petals, fragrant, long flowering period, medium disease resistance.
- 'J.P. Connell'—A vigorous shrub, 3 to 5' high and 2 1/2 to 3 1/2' wide; flowers are yellow, 30- to 70-petaled, 3 to 4" diameter, fragrant; foliage is dark green; this was the first yellow-flowered form introduced from the Plant Research Centre of Agricultural Canada; it is susceptible to black spot; interestingly, 24 parental types were used in breeding this selection, this represents a long term commitment to a breeding program; see *HortScience* 23:783–784, (1988) for additional information about this and 'John Davis'.
- 'Marie Victorin'—Dieback shrub; repeat flowering with peachy pink flowers.
- 'Rugosa Ottawa'—Introduced in 1984 as a source of insect and disease resistance for breeding roses; offers resistance to the 2-spotted spider mite, strawberry aphid, black spot, and mildew; flowers are purple; habit is rounded-mounded, 5' by 5'; cold hardy and flowers repeatedly but sparingly; see *HortScience* 19:896–897 (1984).
- 'William Baffin'—A cold hardy, disease resistant, strong climber; grows 9 to 10' high; 2 1/2 to 3" diameter, 20-petaled, deep pink flowers open in spring with a second flush in late summer; leaves are glossy dark green; see *HortScience* 18:962 (1983); probably Zone 4.
- 'William Booth'—Spreading-trailing, 4 to 5' by 8'; deep red buds open to medium to light red, single flowers in clusters of 8 to 10; everblooming; highly disease resistant.

PARKLAND SERIES

Hybrids of native prairie roses from Morden Research Station, Canada. Introductions do freeze back but flowers on new growth of the season. Cultivars include:

- 'Adelaide Hoodless'—Bright red, 12 petals, medium disease resistance.
- 'Cuthbert Grant'—Velvety red, 18 petals, medium disease resistance.
- 'Hope for Humanity'—Deep wine-red flowers; dieback shrub, regrowth to 2'; good resistance to powdery mildew.
- 'Morden Blush' (PP 8,054)—Light pink, 50 petals, medium disease resistance.
- 'Morden Centennial'—Pink, 50 petals, medium disease resistance.
- 'Morden Fireglow' (PP 8,060)—Red, 28 petals, medium disease resistance.
- 'Morden Ruby'—Ruby red, 70 petals, medium disease resistance.
- 'Morden Snowbeauty' (PP 11,730)—Single white flowers; glossy green leaves; everblooming.
- 'Morden Sunrise' (PP 13,969)—Yellow, edged in pink; single.
- 'Prairie Dawn'—Pink.
- 'Winnipeg Parks' (PP 9,122)—Cherry red, double.

DRIFT ROSE SERIES

Only witnessed in 2008 at the Farwest Nursery Show, Portland, OR in August, then at Hawksridge Nursery in September. Naturally dwarf hybrids of groundcover/shrub and miniature roses, they have glossy dark green foliage, good resistance to rust, powdery mildew and black spot, and cold hardiness to Zone 5. Witnessed Coral Drift and Pink Drift with flowers only at end of shoots; certainly not overwhelming; relatively clean foliage for September in Zone 7. Observed in mid May and they were spectacular. Prune back in late winter to encourage vigorous growth and flowers; deadhead during growing season. Bred in France by Meidiland; marketed in the United States by Conard-Pyle, West Grove, PA.

Cultivars include:

- Coral Drift® ('Meidrifora', PP 19,148)—Bright coral-orange, 1 1/2" diameter, double (20 to 25 petals) flowers cover this small, mounding shrub from mid-spring to mid-fall; semi-glossy medium to dark green foliage; fully winter hardy and disease-resistant; grows 1 1/2' by 2 1/2'.
- Ivory Drift® ('Meijeunom', PP 19,143)—One of the earliest roses to flower and one of the most floriferous in the Drift series; it has exceptional disease resistance.

- Peach Drift® ('Meiggili', PP 18,542)—Soft peach, 1 1/2" diameter, double flowers composed of 15 to 20 petals; semi-glossy, mid-green foliage; rounded bushy habit, 1 1/2' by 2'; good disease resistance.
- Pink Drift® ('Meijocos', PP 18,874)—Pink, semi-double, 1 1/2" diameter flowers, typically with 7 to 8 petals; semi-glossy, mid-green foliage; low, creeping habit, 1 1/2' by 3'; good disease resistance.
- Red Drift® ('Meigalpio', PP17,877)—Medium red, 3/4" diameter, double flowers, 15 petals; semi-glossy, medium green foliage; low, creeping habit, 1 1/2' by 2 1/2'; good disease resistance.
- White Drift® ('Meiglise', PP 15,960)—Conard-Pyle is calling this the first true miniature shrub rose; flowers are 1 to 1 1/2" wide and have a strong spicy fragrance; the pure-white flowers open in late June and continue well into fall.

EASY ELEGANCE® ROSE SERIES

Bred by Ping Lim for Bailey Nurseries, St. Paul, MN, incorporating great flower colors, foliage, disease resistance and cold hardiness. I observed them at Bailey's as well as at McCorkle's in Dearing, GA but do not have a good handle on their overall performance. Suggest interested readers visit www.easyelegancerose.com. I checked the site in mid September, 2008 and found 18 listed with photos and information. I was told that Knock Out® is not hardy in Minnesota (Zone 4) and several of the Easy Elegance® are. The 2009 Bailey catalog lists 10 of 18 with Zone 4 designations.

FLOWER CARPET® SERIES

Flower Carpet® (PP 7,282) and the series resulted from 35 years of breeding by Noack Rosen and are marketed by Anthony Tesselaar (www.tesselaar.com). I have not been impressed with everyday performance, especially compared to Knock Out® roses. Have grown some of each in Georgia trials and my personal gardens. I have no vested interest in either group as good garden performance is the overriding criteria. Flower Carpet® roses are described as possessing "natural strength again rose diseases." Might mention that one of my Chapel Hill neighbors has double Knock Out® and pink Flower Carpet® in the front garden. On September 18, 2008, the Knock Out® was loaded with flowers and buds, the foliage clean; the Flower Carpet® with minimalist flowers at the end of long, spreading shoots, about one-half the basal foliage absent.

Listed by color and readers can go to the website for photos and information. Colors include Amber, Appleblossom, Coral, Yellow, Pink, Pink Supreme, Red, Scarlet and White. A few of note include: Flower Carpet® Amber (burnt orange buds, amber-apricot, double, 2 to 2 1/2" diameter flowers with brighter yellow centers that fade to peach-pink, glossy dark green foliage, 2 to 3' high by 3' wide); Flower Carpet® Pink Supreme (deep cherry buds that open bright pink, maturing to warm pink, double flowers; medium-size, glossy dark green leaves, resistant to black spot and mildew); and Flower Carpet® Scarlet (double, bright scarlet flowers, glossy dark green foliage, 2 to 3' by 3 to 3 1/2').

KNOCK OUT® ROSES

Kudos to Bill Radler, Wisconsin, the breeder of the Knock Out® series. See www.theknockoutrose.com/breeder.cfm. He made the *world* more beautiful, literally eliminated the need for chemicals, and brought the ROSE back into everyday gardens. I see them everywhere! Commercial and residential landscapes are overflowing with them. In Zone 7, flowers are guaranteed from April to October–November and coupled with attractive red-purple new growth (in mild winters holding some leaves into spring), have replaced everyday, single-season flowering shrubs like deutzias, mockoranges, and my beloved viburnums. Color, color, color, fragrance also, without great effort. Still flowering prolifically on December 17, 2001 in Cairo, GA. The original Knock Out® ('Radrazz', PP 11,836) was the 2000 AARS winner.

The following list of the Knock Out® series is based on my experiences and the literature.

Original—Cherry-red, single, 3 to 3 1/2" diameter, fragrant; the best in author's opinion.

The Double Knock Out® ('Radtko', PP 16,202)—Cherry-red, double, 3 to 3 1/2" diameter, fragrant.

The Pink Double Knock Out® ('Radtkopink', PP 18,507)—Bright pink, double, 3 to 3 1/2" diameter, fragrant.

The Pink Knock Out® ('Radcon', PP 15,070)—Bright pink, single to semi-double, fragrant

The Rainbow Knock Out® ('Radcor', PP 17,346)—Coral-pink with yellow centers, single, fragrant.

The Blushing Knock Out® ('Radyod', PP 14,700)—Light pink, semi-double, flowers cupped, light fragrance.

Sunny Knock Out® ('Radsunny', PP 18,562)—Two-inch, pointed, bright yellow buds open to 3" diameter, single, cream-white flowers when fully open, no fragrance; more upright habit, 4 1/2' by 3'; dark green foliage, exceptional resistance to black spot and powdery mildew although I suspect slightly more disease susceptible being a yellow rose; hardy to Zone 4; introduced via Conard-Pyle.

White Out™ ('Radwhite', PPAF)—The first white in the series; single, 5-petaled, 3 to 3 1/2" across, citrusy fragrance; dark green foliage; 3 to 3 1/2' high.

Also bred by Bill Radler are the following Carefree® selections. Best included here although not officially part of the Knock Out® Series.

Carefree Celebration® ('Radral')—Shrub rose with 1 1/2 to 1 1/2", ovoid, brick-orange buds that open to 2 to 2 1/2", coral-salmon flowers; 3 to 5 flowers per stem; bronze-red new growth, medium green mature; excellent mildew and black spot resistance; to Zone 5 hardy; Bill Radler hybrid; offered via Conard-Pyle.

Carefree Sunshine™ ('Radsun', PP 13,063)—Double yellow, fragrant, 2 1/2 to 3 1/2" diameter flowers in profusion in April–May (Chapel Hill, NC), sporadic later, not as floriferous as Knock Out®, which grows next to it in Susy's garden; about 5' high and wide in 5 years; pruned to keep it in bounds; leaves with some black spot; strong canes heavily armed with large, sharp, recurved, prickles; sets 3/4", top-shaped, orange fruit in abundance.

OSO EASY™ ROSES

Oso Easy™ roses are offered by Spring Meadow Nursery. Described as disease resistant. I have yet to test any. All carry the Oso Easy™ trademark and are patented or in process. They include: Cherry Pie (red), Fragrant Spreader (pink), Honey Bun (blush pink, butter yellow to white; highest disease resistance), Paprika (red-orange with yellow eye), Peachy Cream (peach to cream), and Strawberry Crush (strawberry pink to cream). Most were hybridized in Europe, so long-term performance is unknown, especially in Zone 7 to 9 where long growing season, heat, drought, and humidity stress roses like nowhere else. The Oso Easy™ series is listed to Zone 5.

Rosmarinus officinalis L. — Rosemary

(rös-ma-rī'nus o-fis-i-nā'lis)

FAMILY: Lamiaceae

LEAVES: Opposite, simple, evergreen, 3/4 to 2" long, 1/16 to 1/8" wide, linear, narrow, entire, revolute margin, lustrous dark green above, white-tomentose beneath (gray-green effect), thick, aromatically fragrant when bruised, sessile.

Rosmarinus officinalis forms a 2 to 4' high (to 6 to 7' in favorable climates) and wide, irregular, evergreen shrub. The needle-like foliage is often gray-green and contrasts nicely with other dark green foliage shrubs. The leaves when bruised emit a potent, unmistakable, aromatic odor. The pale to dark blue, 1/2" long flowers are borne in the leaf axils from fall to spring. Flower effect is often reduced because flowers blend with foliage.

Flowers are most pronounced during December, January, and February in Athens and colors are also the deepest. Flower color fades in the heat. Fruit is a nutlet. Easily cultured. Withstands drought and about any soil except those that are permanently wet. Full sun. Displays excellent salt tolerance. Deer resistant. Withstands pruning and can be fashioned into a low hedge. Has numerous uses in the garden but often kind of wild and woolly in appearance; this is not particularly bad because so many southern landscape plants look like they were dressed in tuxedos. I have become increasingly fond of this species over the years.

CULTIVARS: Numerous; about 75 listed in RHS Plant Finder 2007–2008; some with deep green foliage, others gray-green; I see them with increasing frequency in southeastern gardens; make worthy fillers and the fine-texture contrasts with larger-leaved shrubs.

'Arp'—Upright habit, vigorous growing, gray-green foliage, lemon-scented, sky-blue flowers; considered a Zone hardier (6) than typical.

'Beneden Blue' ('Collingwood Ingram')—Offers vivid blue, almost gentian blue flowers, narrow, dark green leaves and semi-erect habit; listed as a cultivar of var. *angustissimus*.

'Blue Spire'—Light green, narrow leaves and clear blue flowers on an erect, compact shrub.

'Huntington Carpet'—Blue flowers, dark green leaves that are silvery beneath on a compact, semi-prostrate, dwarf, mounding shrub that grows less than 1' tall; introduced by Huntington Botanical Garden, San Marino, CA; would be classified in Prostratus Group.

'Lockwood de Forest'—Akin to 'Prostratus' in habit but has lighter green foliage and bluer flowers, 2' by 4' to 8'; Prostratus Group.

'Majorca Pink'—Lilac-pink flowers, relatively broad leaves on an erect shrub.

'Miss Jessop's Upright'—Erect, robust form with broad, deep sea green leaves; considered one of the hardiest.

'Prostratus' (Prostratus Group)—More trailing (12 to 18") and irregular than the species and less hardy (Zone 8).

'Roman Beauty' (PP 18,192)—Upright habit, mid green foliage, and violet-blue flowers.

'Roseus'—Pink flowers.

'Severn Sea'—Fine blue flowers on a free-flowering, arching-spreading shrub.

'Tuscan Blue'—Clear blue flowers, light green rather broad leaves on an erect shrub.

I have grown the plant in our Georgia and North Carolina gardens with no winter injury. However, in Massachusetts the plant winter-killed at -5 to -10°F . Excellent garden plant because of foliage color and fragrance. Use the better blue-flowered forms. Have seen it used in containers and other places where it can cascade. The aromatic leaves are employed in cooking, sachets, etc. Easily rooted from cuttings about any time of year with a rooting hormone; the rooting medium should not be excessively moist. Southern Europe, Asia Minor. Cultivated for centuries. Zone (6)7 to 8(9).

Rostrinucula dependens (Rehd.) Kudô — Weeping Rostrinucula

(rös-trī-nū'cū-la de-pen'denz)

FAMILY: Lamiaceae

LEAVES: Opposite, simple, oblong-elliptic to obovate-elliptic, 4 to 6" long, 3/4 to 1" wide, shallowly serrate, short acuminate to acute, cuneate, glabrous and mid-green above, gray-green below; petiole—virtually sessile.

STEM: Squarish, silver-gray, pubescent.

Rostrinucula dependens was originally introduced as a *Buddleia* but when it flowered, the *Buddleia* jig was exposed. Actually a 3'(5') high, broad-mounding, deciduous, half-hardy shrub that is aligned to the mint family. Gracefully mounding-arching with mid-green leaves and 8 to 10" long, pink flowers, on new growth, in summer–fall. Flowers are akin to pendulous catkins at the ends of the arching branches, certainly not overwhelming but do catch the eye. The small pink flowers appear in the axils of gray-felted bracts, in dense, pendulous, terminal, indeterminate spikes, with long-exserted pink stamens and styles. Flowers open over a long period in an acropetal fashion, i.e. base toward apex, and remind of an upside-down *Elsholtzia stauntonia* inflorescence. In Athens, flowering initiates in September continuing into late October. Based on performance in Athens, well-drained soil, and full sun, suit it best. Reasonably heat and drought tolerant. Best in borders, shrub and perennial, where it can be pruned/shaped in late winter. Zone 7 to 9(10). Two species, this and *Rostrinucula sinensis* (Hemsl.) C.Y. Wu, are endemic in China. The latter species has a rounded leaf base and the leaf underside is densely covered with white, stellate pubescence. Introduced 1985.

Rubus L.

FAMILY: Rosaceae

The berries: black-, rasp-, dew-, wine-, thimble-, salmon-, cloud-, marion-, ad infinitum, continue to climb the fire escape and into the sixth edition. The cultivated, fruiting taxa are beyond the parameters of this *Manual* but several species and cultivars offer beautiful flowers, foliage, stem colors, and textures. Be leery, because they are prickly and lethal to work with and also invasive. Check local fields that are no longer in cultivation. The chances of finding the *Rubus* invasion are high. Abundant literature on invasiveness. A web search is frightening.

Most *Rubus* flower on old growth so cut back canes after flowering. However, for best foliage and stem color and impact cut back stems in late winter.

Species are categorized by landscape attributes. With the exception of *R. pentalobus* (*R. calycinoides*), all are suckering shrubs growing 3 to 6'(10') tall. More than 250 species in Europe and North America and their taxonomy is quite muddled. Apomictic species as well as hybrids cloud the picture.

GROUND COVER

Rubus pentalobus Hyata (also listed as *R. calycinoides* Hyata & Koidz.; *R. rolfei* S. Vidal according to RHS Plant Finder 2007–2008), (rū'bus pen-ta-lō'bus) is an evergreen spreading or prostrate shrub with

3- to 5-lobed, wrinkled, lustrous dark green leaves, brown pubescent, non-prickly stems, white flowers, and red fruits. Large planting at Sarah P. Duke Gardens had abundant orange fruits on June 30, 2006. This could have been a transitional stage to red although fruits were mature size, none with a red blush. 'Emerald Carpet' is a more compact clone with smaller leaves than the species, leaves turn burgundy in autumn, space 2 to 3' apart to achieve good coverage. I have observed a yellow-foliage form, the leaf color diminishing with heat. Patented (PP13,436) as 'Golden Quilt' and described as having yellow-green foliage that turns green with maturity; burgundy fall foliage; discovered by Bobby Saul, Atlanta. Taiwan. Zone 7 to 9. Widely promoted but I have doubts about its staying power in heavy wet soils, high humidity and heat.

FLOWERS

Rubus amabilis Focke (rū'bus a-mab'a-lis) bears solitary, white, 2" diameter flowers on a 6' framework, western China; **R. rosifolius** Sm. (formerly *R. coronarius* (Sims) Sweet (rū'bus rōs-i-fō'lē-us) with double, white flowers; **R. deliciosus** Torr., (rū'bus dē-lis-ē-ō'sus) Rocky Mountain Flowering Raspberry, produces pure white, 2" diameter flowers, western United States, Zone 5; **R. odoratus** L., (rū'bus ō-dor-ā'tus) Flowering Raspberry, offers rich pink-purple, fragrant, 1 to 2" diameter flowers in June-July, abundant in southern Appalachians into New England, Zone 5, 'Albus' is a white-flowered form of *R. odoratus*; **R. 'Benenden'**, a hybrid between *R. deliciosus* and *R. trilobus* Ser., with 2 to 3" diameter, white flowers and golden-stamened centers, described as sterile, no spines, witnessed 10 to 12' high plants, stems without prickles, in flower in early May, Zone 5. **R. spectabilis** Pursh, (rū'bus spek-tab'i-lis) Salmonberry, produces bright rose (red), fragrant, 1 to 1 3/4" diameter flowers in April; 'Olympic Double' ('Flore Pleno') bears beautiful double rose-red flowers, grows 3 1/2 to 5' high; have touched the species in the Hoh Rain Forest, Washington.

Rubus deliciosus

Rubus odoratus

FOLIAGE

Rubus idaeus L. 'Aureus' (rū'bus ī-dā'ē-us) produces bright yellow foliage, also listed as 'Mellow Yellow' or at least it appeared to be the same plant at Hyde Hall May 1, 1999; **R. microphyllus** L. f. 'Variegatus' (rū'bus mī-kro-fil'us) offers 3-lobed, to 3" long leaves marbled pink and off-white, have photographed the plant in Europe but have not seen it in the United States, Zone 9; **R. thibetanus** Franch. (rū'bus thī-bet'an-us) bears large, 8 to 9" long, 7 to 13 foliolate leaves, dark green above, white tomentose below; 'Silver Fern' has silver gray, attractively cut (dissected) leaves and waxy, bloomy, silver-white stems, Western China, Zone 6.

STEMS

The following species have white-silver stems that are striking in winter. All have prickles or bristles. **Rubus biflorus** Buch.-Ham. ex Sm., (rū'bus bī-flor'us) white flowers, Zone 9; **R. biflorus** var. **quinquiflorus** Focke (rū'bus bī-flor'us kwin-kwa-flor'us) is described as having brilliant white stems in winter, vigorous, large; **R. cockburnianus** Hemsl., (rū'bus cok-burn-i-ān'us) purple flowers, not as vigorous as above,

Zone 6, Goldenvale™ ('Wyego') is lower growing, less invasive, leaves yellow, stems white in winter, observed at Wisley in March and early June, the stems and the foliage quite striking, respectively; ***R. coreanus*** Miq. (rū'bus kor-ī-ān'us); ***R. koehneanus*** Focke (rū'bus kōn-ī-ān'us), ***R. lasiostylus*** Focke, (rū'bus lā-sē-ō-stī'lus) maroon flowers, Zone 6; and ***R. thibetanus*** Franch., (rū'bus thī-bet-ān'ē-us) purple flowers, purplish brown stems covered with white wax, Zone 6. See *Arnoldia* 50(3):12–15 (1990) for a discussion of The Ghost Bramble, ***R. lasiostylus* var. *hubeiensis*** T.T. Yu et al. (rū'bus lā-sē-ō-stī'lus hū-bē-ī-en-sis). Also, *The Garden* 117(12):578–579 (1992) for Roy Lancaster's account of *R. biflorus*.

Also, ***R. phoenicolasius*** Maxim., (rū'bus fe-nēs-ō-lā'sē-is) Wineberry, has dense, glandular-bristly, red stems that are sparsely prickly, white to pale pink flowers, Zone 5.

*Rubus idaeus*

Ruscus aculeatus L. — Butcher's Broom

(rus'kus ä-kū-lē-ā'tus)

FAMILY: Liliaceae, Ruscaceae

LEAVES: Actually not really leaves but modified stems called cladophylls (cladodes), evergreen, ovate, 3/4 to 1 1/2" long, 1/4 to 3/4" wide, dark green, slightly glossy on both sides, tapering at the apex to a slender stiff spine, extremely sharp to the touch.

STEMS: Grooved, dark olive-green, glabrous.

Ruscus aculeatus is an unusual plant that can be used in deep shady corners of the garden where few plants will thrive. It forms a neat, 1 1/2 to 3' high mound of rather erect, rigid stems. The plant tends to sucker and will gradually form a rather good-sized colony. The dull white, 1/4" diameter flowers (March–April) are borne in the center of the cladophyll and make a curious sight. Plants are generally dioecious and male and female must be present if fruit set is to occur. The oblong fruits (berry) are glossy bright red, 1/3 to 1/2" long and borne in the center of the cladophyll. They ripen in September–October and persist into the following spring. Fruits are genuinely handsome and appear as small, red cherries studding the branches. This species, although not spectacular, does quite well in Zone 7. One particular plant on campus was literally smothered by shade but nonetheless maintained a rather dense and healthy constitution. The plant is quite prickly. It is frequently dried, dyed red (various colors), and sold for Christmas decorations. Bisexual forms are in commerce. Was given a hermaphrodite form from Kew Gardens in 1993 and carried it home in my back pack, the entire time being poked (jabbed) in the back. Plant has fruited in the Dirr garden. 'Christmas Berry' (PP 16,680) is an upright form with glossy green cladophylls; produces numerous, glossy, bright red fruits; assume this is hermaphrodite. 'John Redmond', another perfect-flowered selection, is listed by Van Vliet Plants. The glistening red fruits nestled among the dark green leaves are extremely attractive. 'Sparkler' is listed as purple-fruited; I assume this is hermaphrodite. 'Wheeler's Variety' grows to 2' high and wide, produces brilliant scarlet berries without the presence of a male, obviously a perfect-flowered form. As container plants in shady courtyards, patios, window boxes, a superb choice. Extremely tolerant of dry soils. The plant in our garden grew under a *Quercus falcata* and thrived. Might mention that I have encountered var. ***angustifolius*** with narrower leaves; ***R. colchichus*** P.F. Yeo, with large (6 to 7" long by 3" wide) cladodes, the flowers produced on the lower surface; and ***R. hypoglossum*** L., with leaves larger than *R. aculeatus*, not as big as *R. colchichus*, and large, cherry-red fruits. The latter forms a dense clump-mound about 2' high. More for the collector but again the fruits are appealing. Probably best in Zone 7 to 8, 9 to 10 on West Coast. A report from Florida lists bacterial leaf spot, *Pseudomonas andropogonis* on *Ruscus hypophyllum* L. I cannot remember any disease associated with *Ruscus aculeatus*. Europe, northern Africa and the Near East. Cultivated before 1750.

Salix alba L. — White Willow

(sā'liks al'ba)

FAMILY: Salicaceae

LEAVES: Alternate, simple, lanceolate, 1 1/2 to 4" long, 1/4 to 5/8" wide, acuminate, cuneate, serrulate, bright green above, glaucous and silky beneath; petiole—1/4 to 1/2" long, with small glands; stipules—lanceolate.

BUDS: Terminal—absent, laterals about 1/4" long, oblong, rounded at apex, smooth, more or less silky-downy, flattened and appressed against stem, a single bud scale visible, rounded on back, flattened toward the twig, yellow to yellowish brown.

STEM: Rather slender, light yellow-green to golden brown, smooth and shining or dull with more or less dense covering of fine silky hairs, bitter to taste.

SIZE: 75 to 100' in height with a spread of 50 to 100'; national champion is 70' by 51' in Russell, VA with a 280" trunk circumference.

HARDINESS: Zone 2 to 8(9).

HABIT: Large, low-branching tree with long branches and flexible stems forming a broad, open, round-topped crown.

RATE: Extremely fast, 3 to 4' a year over a 20-year period.

TEXTURE: Fine in leaf, medium in winter.

BARK: Yellowish brown to brown, somewhat corky, ridged-and-furrowed; there was a beautiful specimen at Smith College Botanic Garden, Northampton, MA, with a distinctly corky-textured bark, the correct identity of the Smith tree may be *S. ×chrysocoma* Dode ('Chrysocoma' = *S. alba* 'Vitellina' × *S. babylonica*). GRIN lists *S. ×chrysocoma* as *S. ×sepulcralis* Simonk. Nothovar. *chrysocoma* (Dode) Meikle.

LEAF COLOR: Bright green above, glaucous green beneath (silvery) in summer; may turn excellent golden yellow in fall, often variable; willows are one of the first plants to leaf out in spring and the last to drop their leaves in the fall; have seen new leaves by late February and old leaves into early January in Athens.

FLOWERS: Dioecious, entomophilous and also anemophilous; male and female borne in upright catkins; the males are quite showy and represent the "Pussy" willow character which is familiar to everyone; most are insect pollinated; on this species catkins 1 3/4 to 2 1/4" long on leafy stalks, stamens 2, free, ovary sessile, conical and glabrous.

FRUIT: Two-valved capsule containing a number of cottony or silky hairy seeds.

CULTURE: Easily transplanted because of fibrous, spreading, suckering root system; prefers moist soils and are frequently found along streams, ponds, rivers and other moist areas; full sun; pH adaptable but do not like shallow, chalky soils; prune in summer or fall.

DISEASES AND INSECTS: Willows, like poplars, are afflicted by numerous problems such as bacterial twig blight, crown gall, leaf blight, black canker, cytospora canker, many other cankers, anthracnose, gray scab, leaf spots, powdery mildew, rust, tar spot, aphids, imported willow leaf beetle, pine cone gall, basket willow gall, willow lace bug, willow flea weevil, mottled willow borer, willow shoot sawfly, willow scurfy scale, nematodes, and other selected insects. Santamour and Batzli, *J. Arboriculture* 16:190–196 (1990), reported on the relative susceptibilities of *S. alba*, *S. babylonica* and 25 weeping willow clones to root-knot nematodes; most taxa were susceptible except for *S. babylonica* 'Babylon'.

LANDSCAPE VALUE: One of the best upright willows for landscape use; good for moist, wet places where little else will grow; wood is actually tougher than *Populus* but still very susceptible to ice and wind storms; tends to be a dirty street tree as do all willows because leaves, twigs, branches and the like are constantly dropping throughout the season; I am often mesmerized by the weeping willows, particularly when sited along water; on our campus several large weeping willows *always* have litter (leaves, small shoots, large shoots) under the canopy; additionally the surface root system out-competes other vegetation and man-made structures-be leery.

CULTIVARS:

'Aurea'—Yellowish leaves, yellow-green stems; less vigorous than the species.

'Britzensis' ('Chermesina')—Coral Bark Willow; first year stems reddish to orange-red, must be cut back heavily for good stem color only occurs on young stems; male; the literature is really confusing and contradictory with one reference noting that 'Britzensis' is a distinct cultivar, another saying 'Chermesina' and 'Britzensis' are the same; 'Britzensis' as I have seen it has more orange-red stems and then only on the new growth of the season, it must be pruned or pollarded to encourage the extension shoots that color so vibrantly during winter; have evaluated 'Britzensis' in Georgia trials and stems are yellow-orange suffused red but still beautiful; grew 10' in a single season, not a small plant; grown by the German nurseryman Späth at Britz, near Berlin.

'Caerulea' (var. *caerulea* (Sm.) Rech. f.)—Cricket Bat Willow; only mentioned because it is used for making cricket bats; the leaves are green above, bluish gray below, a female, will grow 80 to 100', pyramidal and erect branching compared to the species.

'Cardinalis'—Described as producing sealing-wax-red stems; female; narrow conical tree, 15 to 20' high.

'Golden Ness'—Brassy-yellow stems; witnessed at Wisley March 1, 2000, did not discern great difference between this and 'Vitellina'.

'Liempde'—Described in Hillier 2002 as a conical tree with upright branches; male; selected in Holland and commonly planted; I do not remember seeing this when visiting the Netherlands; reads as though it may have potential in the U.S.

var. *sericea* Gaudin ('Regalis', 'Sericea', f. *argentea* Wimm.)—Leaves with an intense silvery hue; often called Silver Willow; I saw many willows in The Netherlands and Germany that had the silvery leaf color; apparently this form occurs occasionally in the wild where it is usually of dwarf habit; both surfaces are covered with silvery pubescence; saw 40 to 60' high trees in Germany; beautiful for silver-gray foliage effect, not unlike Russian-olive, *Elaeagnus angustifolia*; could be cut back in winter to force new spring shoots.

'Tristis'—Called the Golden Weeping Willow and certainly one of the hardiest and most beautiful of the weeping types; sometimes listed as *S. vitellina* L. var. *pendula* and *S. alba* 'Niobe' in the trade; this form is also listed as *S. xchrysocoma* or *S. 'Chrysocoma'*; a hybrid between *S. alba*, *S. a. 'Vitellina'* and *S. babylonica*; this is essentially the standard weeping willow and has largely supplanted the other weeping types in gardens; will grow 50 to 70'(80') and produce a broad canopy of graceful golden weeping branches; 'Tristis' is an enigmatic taxon with confusing botanical background; the typical tree, as I have seen it throughout the United States, is immense with large stout ascending (45 to 60° angle) branches with secondary branches steeply pendulous and often sweeping the ground, the whole tree rather dignified and majestic; for point of reference the flowers are male or female on the same or separate branches, or female flowers occupying the terminal part of the catkin, or with bisexual (perfect) flowers; the botanical uncertainties swept aside, it is a handsome tree but can suffer severe breakage and is likely to shed limbs at the drop of a hat or the wisp of a breeze; have seen *S. xsepulcralis* Simonkai, Weeping Willow, utilized as a grex to house var. *chrysocoma* (Dode) Meikle, i.e., *S. a. 'Tristis'* and also var. *salamonii* Carr., a less prominent weeping form with dull green leaves and olive stems.

'Vitellina' (subsp. *vitellina* (L.) Arcang.)—Bright yellow stems, almost egg-yoke yellow, must be cut back like 'Britzensis'; apparently several clones with the characteristics enumerated belong here; have observed this cultivar in Raleigh, NC in winter where it was distinctly yellow; have read a reference to four male weeping clones of *S. babylonica* × *S. alba* 'Vitellina'; the grex name is *Salix xaureo-pendula*; clones are 'J841', 'J842', 'J1010', and 'J1011'; see *J. Jiangsu Forestry, Science and Technology* 23(4):1–5 (1996).

'Vitellina Tristis'—Semi-pendulous form of the above, in commerce before 1815, see 'Tristis' for accurate portrayal.

'Yelverton'—Handsome in winter, the pollarded stems orange-red at ends grading to orange-yellow at their bases, experienced at Wisley March 1, 2006; similar to 'Britzensis'.

PROPAGATION: Seeds have no dormancy and germinate within 12 to 24 hours after falling on moist or wet soil; there is no dormancy known in any species; all willows are easily propagated by soft or hardwood cuttings at anytime of the year; just collect the cuttings and stick them; the stems have preformed root initials; a Czech Republic study noted best rooting of six *Salix* taxa occurred in June into early July; tissue culture has been successful with many *Salix* species.

A "willow rooting substance" that is quite effective in promoting rooting of difficult-to-root plants especially when used in combination with IBA has been described, see Kawase, *Physiol. Plantarum* 23:159–170 (1970) and same author *J. Amer. Soc. Hort. Sci.* 96:116–119 (1971); the young willow stems are cut into small pieces, steeped in water; the cuttings to be rooted are then placed in the extract and allowed to absorb for a period of time; IBA may also be applied in conjunction with the willow extract.

ADDITIONAL NOTES: The use of any willow should be tempered with the knowledge that serious problems do exist. Many are short-lived and require much maintenance to keep them presentable. All are fast-growing and somewhat weak-wooded. The weeping willows do add a light, graceful touch around ponds and streams. Extract of willow bark is one of the precursors of aspirin. Article in *The Garden* 126(3):158 (2001) extolling virtues with photographs of the colored-stem types.

NATIVE HABITAT: Central to southern Europe to western Siberia and central Asia. Naturalized in North America. Long Cultivated.

RELATED SPECIES: The willows are gingerly treated in this text. There are about 250 (300) species generally confined to the northern hemisphere and about 75 species grow in North America. They hybridize freely and it is often difficult to distinguish hybrids from species. Bean, Krüssmann, *The New RHS Dictionary of Gardening* and Newsholme, *Willows, The Genus Salix*, Timber Press (1992) offer more advanced treatments of *Salix* and should be consulted. The latter is a terrific reference and the author mentions 400 species and more than 200 listed hybrids. In all the taxonomic literature I checked, no one cites the same

number of species. Santamour and McArdle, *J. Arboriculture* 14(7):180–184 (1988) attempted to delineate the taxonomy of the various weeping types. I considered following their lead but am not convinced that anyone has a solid grasp on *Salix* nomenclature. Their paper is worth reading. The following are used in landscaping to one degree or another.

***Salix babylonica* L.** — Babylon Weeping Willow
(sā'liks bab-i-lon'i-ka)

LEAVES: Alternate, simple, lanceolate to linear-lanceolate, 3 to 6" long, 1/2 to 3/4" wide, acuminate, cuneate, serrulate, light green above, grayish green beneath, with distinct venation, glabrous; petiole—1/5" long; stipules—rarely developed, ovate-lanceolate, revolute.

STEM: Long, pendulous, glabrous except at nodes, brown, on upper surface reddish brown and never yellow as in *S. alba* 'Tristis'.

Salix babylonica grows 30 to 40' with a comparable spread. National champion is 102' by 102' in Burke's Garden, VA. A very graceful, refined tree with a short, stout trunk and a broad, rounded crown of weeping branches that sweep the ground. True *S. babylonica* is an enigma and appears almost to be a plant of the past. In European countries and the United States, it is almost nowhere to be found. In fact, trees that I have seen labeled as *S. babylonica* were usually something else. The normal form is a female. 'Blue Fan' with splashed blue-green foliage is described. 'Crispa' ('Annularis') is a cultivar with spirally curled leaves. I have read several historical renderings concerning this tree and am almost convinced it does not exist in gardens except in the minds of those who wish to associate it with the hanging gardens of Babylon and the tree described therein was *Populus euphratica*. Apparently, three different clones, maybe more, exist under this name. The bottom line translates to another weeping willow other than *S. babylonica*. Santamour and McArdle, *J. Arboriculture* 14(7):180–184 (1988) propose the cultivar name 'Babylon' for the tree described above. Introduced 1730. China. Zone (5)6 to 8. In laboratory freezing tests, the species survived –76°F. See *Plant Physiology* 95:871–881 (1991).

***Salix ×blanda* Anderss.** — Wisconsin Weeping Willow
(sā'liks blan'da)

Salix ×blanda perhaps more correctly listed as *S. ×pendulina* Wender. 'Blanda', Wisconsin Weeping Willow, is a hybrid between *S. babylonica* and *S. fragilis* with increased hardiness (Zone 4). It is not truly weeping although the branches are somewhat pendulous. Grows to 40' high. The leaves are glossy dark green, rather thick and bluntly toothed. Stems are olive-brown, glabrous. There is some indication this may be a hybrid between *S. babylonica* and *S. pentandra*. This is a female clone. First described around 1867. To my knowledge not available in commerce in the United States. 'Elegantissima', a more strongly weeping form, resides herein. Zones 4 to 7.

***Salix caprea* L.** — Goat Willow, Pussy Willow
(sā'liks kap'rē-a)

LEAVES: Alternate, simple, broad-elliptic to oblong, 2 to 4"(5") long, 1 to 2 1/4"(3") wide, acute, rarely rounded at base, irregularly and slightly toothed or nearly entire, pubescent at first, finally glabrate, rugulose and dark green above, gray-pubescent beneath and reticulate; petiole—1/3 to 2/3" long; stipules—oblique-reniform, serrate.

BUDS: Stout at maturity, 1/4 to 1/2" long, colored and clothed as the twigs, purplish brown; flower (catkin) buds larger than others.

STEM: Stout, yellowish brown to dark brown, purplish brown, pubescent to glabrescent.

Salix caprea is an erect, small tree growing 15 to 25'(30') with a 12 to 15' spread. The major asset is the large (1 to 2" long), male catkins which appear in March and early April and are affectionately referred to as Pussy Willows because of their silky softness. This species is often confused with *Salix discolor* Muhl., the true Pussy Willow, which is native to wet areas over much of the eastern United States, but that species has deep brown branches and very glaucous (almost bluish white) lower leaf surface. *Salix discolor* is quite susceptible to canker and is considered inferior for landscape use although neither species is a plant of the first order. *Salix caprea* 'Pendula' ('Kilmarnock') is a handsome weeping form (male) that can be used as a ground cover or raised on a standard to produce a small weeping tree. This clone was discovered on the banks of the River Ayr before 1853 and was put into commerce by Thomas Lang of Kilmarnock, Ayrshire,

Scotland. There are two clones under the above name; one female, the other male. The female is the most common form in cultivation in the United States. Roy Lancaster named the female form 'Weeping Sally'. The cultivars are often grafted on a standard to produce a rather pretty, small, weeping tree. When not grafted or staked, the plant forms a large-trailing mound and serves almost a ground cover function. There is also a white-variegated leaf form that does not appear to be stable. In 2005, I witnessed an unnamed, contorted, spirally-oriented-stemmed plant of 'Pendula' ('Kilmarnock') at Architectural Trees, Bahama, NC. Branches were unique with the gray catkins (male). It was grafted on a standard. Hillier 2002 listed the name as 'Curly Locks', a sport of 'Kilmarnock', found in Holland in 1990. Europe to northeast Asia and northern Iran. Long cultivated. Adapted from Zone 4 to 8.

***Salix chaenomeloides* Kimura** — Japanese Pussy Willow
(sā'liks kē-nom-el-oy'dēz)

LEAVES: Alternate, simple, narrow elliptic to oblong or obovate, 2 to 5" long, 1/2 to 2" wide, short acuminate or acute, cuneate, serrate with incurved teeth, young leaves reddish brown, dark blue-green at maturity, glabrous, finely hairy beneath, 18 to 22 vein pairs; petiole—1/4 to 1/2" long; stipules—lanceolate, persistent.

BUDS: Flower—large, 1/2 to 3/4" long, plump, ovoid, irregular, lustrous reddish purple, glabrous to slightly pubescent at base; vegetative—smaller, 1/8 to 3/8" long, appressed to stem, flattened, red-brown, pubescent.

STEM: Stout, hairy in youth, becoming glabrous, reddish purple on current year's growth, becoming shiny brown, glabrous, with small, lip-like lenticels; pith—solid, white on first year stems, brown on second.

Salix chaenomeloides was given to me by Don Shadow about 20 years past. The original plant in our test plots was 12' by 12' in two seasons. Probably will mature between 15 to 20' high. The large, red flower buds are almost more handsome than the 1 to 2"(3") long, silky, pink- to rose-tinged, male catkins. The yellow-orange anthers follow and provide contrast. Extremely easy to grow and many individuals collected cuttings from the original plant. Probably better than *S. caprea* in Zone 7 and 8. Observed a large plant in Mark Johnson's, Dearing, GA garden that was prospering. 'Mt. Aso' produces abundant, gray-white, caterpillar-like catkins in late March—early April. Japan. Zone 6 to 8.

***Salix elaeagnos* Scop.** — Rosemary or Hoary Willow
(sā'liks el-ē-ag'nos)

LEAVES: Alternate, simple, linear to narrow lanceolate, 2 to 6" long, 1/8 to 7/8" wide, tapered at both ends, appearing narrower because of the revolute margins, finely serrate, rather lustrous dark green and glabrous above, covered with a white wool below; petiole—1/4" long; stipules—absent.

Salix elaeagnos is a dense, medium-sized shrub, 15 to 20' high, with long, linear, "Rosemary-like" leaves. The leaves are initially grayish and finally dark green above and whitish beneath. The mature stems are a distinct reddish brown. I noted deep red-purple at Longstock February 20, 1999. Catkins to 2" long, 1/2" wide, appearing before leaves. This is a handsome willow because of the pretty leaves and is recommended for wet areas where few other shrubs can be successfully grown. I first learned the plant as *S. rosmarinifolia* which is a respectable name when one takes into account the similarity of the leaves to Rosemary, *Rosmarinus officinalis*. Have seen *S. rosmarinifolia* equated with subsp. *angustifolia* of *S. elaeagnos*. This is a fine garden plant with wispy gray-green foliage and a delicate texture. Ideally the shrub is best pruned to the ground in late winter to promote the long shoot growth. If not occasionally renewal pruned, it will become leggy. Mountains of central and southern Europe, Asia Minor. Zone 4 to 7.

***Salix exigua* Nutt.** — Coyote Willow
(sā'liks ex'i-gwa)

Salix exigua of the western states (Alaska

to Mexico) offers intense silvery gray, narrow

leaves that maintain color through the summer. Will grow 10'(30') high. ***Salix hastata* L. 'Wehrhahnii'**, (sā'liks has-ta'ta), presents silver-gray, male catkins that turn yellow when the stamens open, the leaves are fresh green, the habit bushy and spreading, 6' by 12'. ***Salix helvetica* Vill.**, (sā'liks hel-vet'i-ka), Swiss Willow, also offers silver-gray leaves and golden catkins on a 2' high and 3' wide shrub. ***Salix integra* Thunb. 'Hakuro-nishiki'** ('Albomaculata', 'Alba Maculata' according to Newsholme), (sā'liks in-teg'ra), produces salmon-pink new shoots aging to white variegation that persists through summer. Will grow 10' high but is best cut back in late winter to encourage strong growth in spring and summer. This cultivar has become more common in U.S. gardens. In Hillsborough, NC, a 15 to 18' high and wide plant grew in the front yard of a home. I said, "It is too large to be 'Hakuro-nishiki'". Close inspection, several photographs, and a nod to its largeness. For the most part, don't base identification on size. All the willows listed above will require cool growing conditions for best foliage color/performance. I suspect most would develop the consistency of a soggy potato chip in Zone 7 to 8.

Salix 'Flame'—Discovered by Melvin Bergeson of Fertile, MN. The habit is oval with a compact, dense-branching habit. Will grow 15 to 20' high. Bark is orange-red in winter. The tips of the branches curl upward and inward. Leaves turn a beautiful golden yellow in fall, long after those of other trees have fallen.

***Salix gracilistyla* Miq.** — Rosegold Pussy Willow
(sā'liks gras-il-is'ti-la)

LEAVES: Alternate, simple, oblong, oval, narrow ovate, 2 to 4"(5") long, 1/2 to 1 1/4" wide, acute at ends, serrulate, gray-green above, grayish and pubescent below; petiole—1/4" long, pubescent; stipules—semi-cordate.

Salix gracilistyla is allied with *S. discolor* and *S. caprea* by virtue of being grown for its showy, 1 to 2" long, male, pinkish or reddish tinged, silky villous catkins produced in March–April. The catkins are quite attractive and there is much variation in the degree of pinkish or reddish suffusion of the gray catkins. It is lower growing (6 to 10') than *S. caprea* and for this reason may be better suited to the small landscape. The leaves are grayish or bluish gray and offer a foliage contrast not available from many species. 'Variegata' is a rather pretty, white-margined form that will revert to the species. Raulston mentioned that the variegation only appears on strong shoots exposed to full sun. Catkins are twice as long as the normal pussy willow grown in the nursery trade. I am unsure whether this variegated form mentioned here is akin to (same as) that listed under *S. caprea*. See *S. melanostachys*, always shifting taxonomically, for it is now listed as *S. gracilistyla* 'Melanostachys'. Japan, Korea, Manchuria, China. Cultivated 1900. Zone 5 to 8.

***Salix koriyanagi* Kimura ex Goerz**, (sā'liks kor-ē-yan'a-gi), has slender stems with small slender catkins, the males with orange anthers. Flowering March 9, 2007, Raulston Arboretum. Years past, the late Bill Wandell game me a plant called 'Rubykins' which appears to belong herein. The smallish, male catkins were pink-rose. I shared the plant with all and it occasionally surfaces in commerce. Probably no larger than 4 to 5' high. The species is cultivated in Japan for basket-making. If the reader somehow obtained a plant and it is still thriving, email me a few photos and brief text. Zone 6 to 7. Korea.

***Salix lanata* L.** — Woolly Willow
(sā'liks la-nā'ta)

LEAVES: Alternate, simple, oval, roundish or obovate, 1 to 2 1/2" long, 3/4 to 1 1/2" wide, undulating surface, abruptly pointed, cuneate, although sometimes rounded or heart-shaped, entire or essentially so, silvery gray pubescence on both surfaces; petiole—1/8 to 1/4" long; stipules—1/3" long, ovate, entire, prominently veined (5- to 6-paired).

Salix lanata has never been seen by the author in a United States garden, but appears like privet in European gardens. It is a small, 2 to 4' high and slightly wider shrub that offers wonderful gray foliage. Among the traditional green-foliaged evergreens and deciduous shrubs it genuinely piques interest. The 1 to 2" long, 1/2" thick male catkins are bright golden and occur at the end of the previous season's growth. No doubt, it requires a cool climate and the heat and humidity of the Midwest and Southeast would prove disastrous. Another gray foliage type is 'Stuartii' which is probably a form of *S. lanata*. In my travels, I have seen several handsome willows in Mr. Adrian Bloom's great garden at Bressingham that would be of interest

to the intrepid willow-o-phile. ***Salix cinerea* L. 'Tricolor'**, Gray Willow, has young leaves that are mottled pink, white and creamy yellow. Plants should be cut back in winter to encourage new growth. Apparently, variegation is lost during summer and another pruning to induce new shoots is warranted. Will grow 6 to 10' high if not pruned. Northern Europe and Northern Asia. Cultivated 1789. Zone 3 to 5.

***Salix matsudana* Koidz.** (listed also as *S. babylonica* var. *pekinensis* Henry — Peking Willow) — Hankow Willow, Peking Willow
(sā'liks mat-sū-dā'na)

LEAVES: Alternate, simple, linear-lanceolate, 2 to 4" long, 1/3 to 3/5" wide, long acuminate, rounded or rarely cuneate, sharply glandular serrate, bright green above, glaucous and glabrous below; petiole—1/4" long.

STEM: Yellowish in youth, later olive-green to greenish brown, glabrous.

Salix matsudana develops an oval-rounded head of fine-textured branches. The emerging leaves are bright green, turn darker green and yellow-green in fall. The species is seldom encountered in the United States. It is closely allied with *S. babylonica* and differences are based on 2 nectaries in the female flower of *S. matsudana* compared to a single of *S. babylonica*. It is more drought tolerant than most willows and for that reason might be worth considering. Australian study showed that the species was salt tolerant. The species matures between 40 and 50'. China, northeast Asia. Zone (4)5 to 7(8). 'Tortuosa' was killed in Orono, ME. Controlled study showed 'Tortuosa' hardy to -76°F. Laboratory and real world experiences are not always on the same field.

'Tortuosa'

Several cultivars include:

'Golden Curls'—A hybrid between *S. alba* 'Tristis' and *S. matsudana* 'Tortuosa' that tends toward a shrubby nature although I have seen small trees; the golden stems have a slight tortuosity and semi-pendulous nature while the leaves are somewhat curled; this is a possibility for cut branches; it might grow 40' high and this is certainly possible considering the parentage, have seen 30' by 15' size categorization; probably correctly listed as 'Erythroflexuosa' (*S. xerythroflexuosa* Rag.; apparently discovered in Argentina around 1971 and brought into the trade by Beardsley Nursery, Perry, OH; Zone 5 to 8.

'Navajo' (Globe Navajo Willow)—A large, 20' high, round-topped tree that is tough and hardy; apparently, this form is used in the southwestern United States; same as 'Umbraculifera'?

'Pendula'—The branches are pendulous, the young branches green and the flowers female; a male pendulous form is also known.

'Scarlet Curls'—Probably has *S. matsudana* 'Tortuosa' as one parent and perhaps *S. alba* 'Britzensis' as the other; the stems are off-red (scarlet) in winter and the older branches golden brown; stems more reddish brown in Zone 7; the leaves are curled somewhat like those of 'Golden Curls'; will grow 30' by 15 to 20'; Zone 5 to 8; in the *S. xerythroflexuosa* grex; not as hardy as 'Golden Curls'; many used in Zone 7 over the years with cankers severely curtailing quality; not typically long term investments.

'Snake' ('Dart's Snake')—A great plant name, sure to inspire confidence in the buying public; not well-known but supposedly an improved form of *S. m.* 'Tortuosa' with perhaps greater branch contortions and canker resistance; have observed and would be hard-pressed to quantify degree of contortion between this and 'Tortuosa'; male.

'Tortuosa' (f. *tortuosa* Rehd., Dragon's Claw Willow)—At one time I looked upon this contorted-stemmed tree with a habit similar to the species as a third-class citizen but have come to appreciate the interesting architecture it brings to the winter landscape; the gray-brown branches are distinctly gnarled and contorted and make a great conversation piece; the tree may grow 50' high but 20 to 30' appears more typical; in a sense, the tree might be pruned heavily in youth like the Europeans pollard the bright red- and yellow-stemmed willows;

'Tortuosa'

the more vigorous shoots tend to have the greatest degree of contortions; a plant for the cut branch (florist) market; the fast growth is a distinct advantage over plants like *Corylus avellana* 'Contorta'; unfortunately, in Zone 7(8), the tree is short-lived; a female clone.

'Umbraculifera' (f. *umbraculifera* Rehd.)—A bushy almost broad-rounded form without a central leader that will grow 25 to 35' high; after 6 years in the Arnold Arboretum a plant was 20' high and 30' wide.

***Salix melanostachys* Mak.** — Black Pussy Willow
(sā'liks mel-an-ō-stā'kis)

Salix melanostachys is a 6 to 10' high shrub, the stems of which in winter assume a rich purple-black color. In spring, the male catkins open a deep purple-black with brick red anthers and finally show yellow. It is an attractive and rather curious shrub. Flowers on naked stems in early March. It is of Japanese origin and considered a hybrid. Should perhaps more correctly be listed as *Salix* 'Melanostachys', *S. gracilistyla* var. *melanostachys* (Mak.) C.K. Schneid., or *S. gracilistyla* 'Melanostachys'; the second the current accepted name according to GRIN. Zone (4)5 to 7. Have not seen it in Zone 7 but suspect it would survive.

***Salix myrsinifolia* Salisb.** (sā'liks mer-sin-i-fō'lē'a), Whortle Willow, is unique for the black stems. Have only seen at Wisley and Rosemoor Gardens in England. Strong contrast with reddish and yellow-stemmed types. Grows 8 to 12' high. Leaves 1 to 3" long, dark green above, glaucous beneath, elliptic-obovate or oblong. Zone 5 to 6. Europe, Western Siberia.

***Salix* × *pendulina* Wender.** 'Elegantissima' (formerly *Salix* × *elegantissima* Koch.) — Thurlow Weeping Willow
(sā'liks pen-dū-lē'na)

Salix × *pendulina* is a hybrid between *S. babylonica* and *S. fragilis*. It is a rather confusing entity and may represent several clones. Grows to 50'. It is hardy to Zone 4. Doubtfully cultivated in the United States. See under *S. ×blanda*. *Salix* × *pendulina* nothovar. *elegantissima* (K. Koch) Meikle according to GRIN.

***Salix pentandra* L.** — Laurel Willow, Bay Willow
(sā'liks pen-tan'dra)

LEAVES: Alternate, simple, elliptic to ovate to elliptic-lanceolate, 1 1/2 to 5" long, 3/4 to 2" wide, short-acuminate, rounded or subcordate at base, glandular-denticulate, lustrous dark green above, lighter beneath, glabrous, midrib yellow, aromatic when bruised; petiole—1/4 to 1/2" long, glandular; stipules—oblong-ovate, often small.

BUDS: Yellow.

STEM: Lustrous, greenish brown, glabrous.

Salix pentandra has the most handsome foliage of all the willows. The leaves are a lustrous, polished, shimmering dark green in summer; grows 30 to 35' high with a compact oval form. Catkins cylindric, 1 to 2" long, 1/2" wide, appearing with the foliage, stamens 5 to 12. The few I have seen in central Illinois were so infested with leaf disease that by August there were no leaves on the tree. Where leaf diseases do not present a problem it could be an interesting specimen. Prairie Reflection™ ('Silverlake') is a handsome, round-headed selection with glossy dark green leaves; introduced by Dr. Dale Herman, NDSU. Native to Europe. Naturalized in eastern United States. Often listed as hardy in Zone 2 and probably best in 2 to 5. Long cultivated.

***Salix* 'Prairie Cascade'**—Introduced by the Morden Research Station in Canada. Apparently a hybrid between *S. pentandra* and *S. ×blanda* with hardiness and glossy green foliage of *S. pentandra* and weeping habit and stem color of the weeping willow. Will grow 35 to 45' high and wide. Zone 3 to 5(6).

***Salix purpurea* L.** — Purpleosier Willow, Basket Willow
(sā'liks pēr-pū'rē-a)

LEAVES: Alternate or occasionally opposite, simple, oblanceolate, rarely oblong-obovate, 2 to 4" long, 1/8 to 1/3"(1") wide, acute or acuminate, cuneate, serrulate toward the apex, lustrous dark blue-green above, pale or glaucous beneath, glabrous or slightly pubescent at first, turning black upon drying; petiole—1/6 to 1/3" long; stipules—small or wanting.

BUDS: Small, appressed, purplish, glabrous.

STEM: Slender, tough branches, purplish at first, finally light gray or olive-gray, glabrous.

Salix purpurea is a rounded, dense, finely branched shrub, 8 to 10'(18') high. Can look horrendous unless properly maintained. When specimens become overgrown, it is best to cut them to the ground. The long shoots are supple and with the fine-textured leaves can be rather attractive. The sessile catkins appear before the leaves, narrow-cylindrical, often curved, 1/2 to 1 1/4" long, 2 stamens, fused, red becoming purple-black. Good plant for wet areas especially to stabilize banks along streams or ponds. In Australia, *Salix purpurea* clones were the most effective stabilizers of the coarse sediment of gully floors. The stems are used in basket making. 'Nana' is a compact form usually less than 5' high and wide with blue-green leaves; often called Arctic Blue Leaf Willow. 'Pendula' is a more or less wide-spreading, weeping form that is often grafted on a standard; makes a rather attractive plant when used in this manner. My notes state that the 'Pendula' at Hillier was truly pendulous. 'Streamco' is a Soil Conservation Service, USDA introduction for stabilizing banks along waterways; grows 12 to 15' by 10 to 12' and suckers and layers producing dense mats that resist erosion. Related species, *S. integra* Thunb. and *S. koriyanagi* Kimura ex Goerz, house the pink-, rose-, white-variegated leaved cultivar that I have seen listed as 'Albomaculata' under *S. integra*. Other names have been applied including 'Hakuro-nishiki'. 'Flamingo' (PP 17,490), with deep red, pink, white shoots, was listed by Pride of Place Plants in Canada; I do not know how different from 'Hakuro-nishiki'; described as a sport of 'Hakuro-nishiki' with more distinctive leaf color that lasts longer. Native to Europe, northern Africa to central Asia and Japan. Long cultivated. Zone 3 to 6(7).

***Salix* 'Rubykins'**—A small shrub, 6' by 6' in 5 years, with slender branches and narrow leaves. The catkins are small, about 1/2" long, reddish. Given to me by Bill Wandell and I shared it with many people. Have seen it listed in Arborvillage, Woodlanders and Spring Meadow catalogs. Origin and taxonomy are shrouded in mystery. May be a form of *S. koriyanagi* (q.v.). Zone 5 to 7.

Salix udensis Trautv. & C.A. Mey. '**Sekka**' (formerly *Salix sachalinensis* F. Schmidt 'Sekka') — Japanese Fantail Willow
(sā'liks ū-den'sis)

LEAVES: Alternate, simple, lanceolate, 4 to 6" long, 3/4" wide, acuminate, cuneate, serrate, lustrous dark green above, glabrous; petiole—1/2 to 1" long.

BUDS: Purplish red.

STEM: Reddish purple when exposed to the sun, lustrous, glabrous.

Salix udensis 'Sekka' is a large broad-rounded shrub or small tree with uniquely twisted branches that are sometimes flat. It grows 10 to 15' high and forms a wide-spreading shrub. It is a male clone. The cylindric, gray, silky, 1" long catkins are produced abundantly along the reddish purple stem. The branches are used for flower arranging. 'Golden Sunshine' (PP 19,370) has rich golden yellow leaves throughout the growing season; 1" long, silky, gray catkins borne on purplish stems; 12 to 15' by 15 to 18' in 5 years. The species is native to northeastern Asia. Introduced 1905. Zone 4 to 7.

Sambucus canadensis L. (listed as *S. nigra* subsp. *canadensis* (L.) Bolli in 2008–2009 RHS Plant Finder) — American Elder
(sam-bū'kus kan-a-den'sis)

FAMILY: Caprifoliaceae

LEAVES: Opposite, compound pinnate, 5 to 11, usually 7 leaflets, each 2 to 6" long, 1/2 to 2 1/2" wide, short-stalked, oval, oblong, rounded-ovate, acuminate, sharply serrate, dark green, slightly puberulous on the veins beneath or nearly glabrous; lowest pair of leaflets frequently 2- or 3-lobed.

BUDS: Solitary or multiple, terminal mostly lacking, brown, few-scaled, small, 1/8" long.

STEM: Stout, pale yellowish gray to gray-brown, heavily lenticellate, glabrous; pith—white; leaf scars broadly crescent-shaped or 3- or 4-sided, large, more or less transversely connected.

SIZE: 5 to 12', quite variable in size, varies significantly with habitat; observed 15 to 20' high plants in Rabun County, Georgia.

HARDINESS: Zone (3)4 to 9.

HABIT: Stoloniferous, multi-stemmed shrub, often broad and rounded with branches spreading and arching.

RATE: Fast.

TEXTURE: Medium in foliage (usually quite dense); coarse in winter.

LEAF COLOR: Dark green in summer, leaves out early in spring; fall color is generally an insignificant yellow-green.

FLOWERS: Perfect, white, actually more yellow-white due to stamens, June–July, borne in 5-rayed, slightly convex, 6 to 10" wide, flat-topped cymes; usually quite profuse and covering the entire plant; I never documented whether flowers are produced on old or new wood, or both, read a comment that plants cut to ground produce large flower clusters implying flowers develop on new growth of the season; flowers contain a volatile oil and are used to produce elderflower water for confectionery and cosmetics; in the Orlando, FL area I saw the plant in flower in March and November and wondered whether it was some mysterious species; it checked out to *S. canadensis* and apparently flowers out of synchronization with the usual June–July sequence so common in Zone 4 to 7(8); have seen it listed as *S. simpsonii* Rehd. in a Florida reference book but this plant looks like nothing more than a southern extension of *S. canadensis*. GRIN lists it as *S. canadensis* var. *laciniata* A. Gray.

FRUIT: Purple-black, August–September, berry-like drupe with multiple pyrenes, about 1/4" in diameter, rather pretty in late summer and certainly sustenance for birds, plant multiple clones for best fruit set.

CULTURE: Transplants readily, does best in moist soils although will tolerate dry soils; thrives under acid or alkaline conditions; full sun; suckers profusely and requires constant attention if it is to be kept in presentable, decent condition.

DISEASES AND INSECTS: Borers, cankers, leaf spots, powdery mildew.

LANDSCAPE VALUE: Fruit is good for jellies, pies, juice, wine and attracting birds; Vitamin C content is 0.3 mg/g; difficult to utilize in home landscape situations because of its unkempt habit; potential near wet areas, naturalizing effect, roadside plantings; foliage forms are rather handsome.

CULTIVARS:

'Acutiloba' (also listed as 'Laciniata')—Leaflets very deeply divided, rather handsome plant, appears to be a weak grower, is nice for foliage effect, 6 to 8' high.

'Adams'—Numerous fruits in large clusters, excellent for jams, pies and wine; 8 to 10' by 8 to 12', selected by William M. Adams of Union Springs, NY.

'Aurea'—Cherry red fruit; broad golden yellow leaves, grows vigorously and looks good throughout the growing season, 8 to 10' by 8 to 12'.

'Maxima'—Flower clusters 10 to 18" in diameter, leaves 12 to 18" long, rose-purple flower stalks, vigorous, may have 11 leaflets instead of the normal 7; was in the Georgia small fruit trials and the inflorescence was larger than a serving platter, so heavy that the stem cascaded.

'Nova'—Huge inflorescences of cream-white flowers followed by dark blue fruits; 6 to 8' high; –30°F cold hardy; use 'York' for cross-pollination.

'Rubra'—A red-fruited form, introduced before 1932 by A.P. Wezel, Smith College.

'Sunbrite'—Broad-rounded shrub, 8 to 10' by 8 to 12'; white flowers in May–June followed by red fruits; leaves golden yellow; listed in 2007–08 Lake County Nursery catalog; may be a rename of 'Aurea' but I am unable to confirm.

'York'—Larger purplish black fruits that mature later than those of 'Adams'; plant is also larger growing; hardy to –30°F; plant with 'Nova' for cross-pollination.

PROPAGATION: Seed, 60 days at 68°F plus 90 to 150 days at 41°F in moist sand. Cuttings, softwood root well; a report on *S. nigra* noted 92% rooting of semi-hardwood cuttings with 4,000 ppm IBA; hardwood taken in late winter also root well; division is also effective.

ADDITIONAL NOTES: Approximately 20 species are distributed around the globe. To my way of defining a great garden plant, the *Sambucus* taxa come up short. However, the foliage when coppiced (cut back) proves effective in the border. This approach is common in Europe particularly with the golden, purple and cut leaf forms. The species appear to thrive with neglect and *S. canadensis* is weed-like over much of eastern North America.

Worthwhile article, "Mind Your Elders," by Ann Lovejoy in *Horticulture* 72(8):34–36, 38, 82 (1995). Also, "Elegant Elderberries" appeared in *Fine Gardening* 59:56–61 (1998). For a genus that receives no more than an askance from the casual gardener, it has received considerable column space.

The introductions Black Beauty® and Black Lace®, selections from *S. nigra*, received considerable marketing in the United States. Plants were bred in England and when I first witnessed Black Beauty® at Hillier in 1999 thought *Sambucus* could become a commodity. Tried Black Beauty® in Athens and it was a disaster . . . lost foliage color, struggling, straggling growth, and died. Possibly Zone 6 and colder but not well adapted to Zone 7. Black Lace® is more delicately cut incised than Black Beauty® and is certainly beautiful for foliage effect. Purple-black foliage color is reduced in heat of South. Scraggly grower in Athens. Both are best sited in sun.

NATIVE HABITAT: Nova Scotia and Manitoba to Florida and Texas. Found in damp, rich soil. Introduced 1761.

RELATED SPECIES:

***Sambucus caerulea* Raf.** (listed as *S. nigra* subsp. *caerulea* (Raf.)

Bolli In RHS Plant Finder 2008–2009; GRIN spells *caerulea* as *cerula* but keeps it as a species) — Blueberry Elder, Blue Elder

(sam-bū'kus ser-ū'lē-a)

LEAVES: Opposite, compound pinnate, 6 to 10" long, 5 to 7(9) leaflets, 2 to 6" long, 1/2 to 2" wide, coarsely serrate, bright green to blue-green, glabrous.

Sambucus caerulea, (*S. glauca* Nutt.), Blueberry Elder, is a large shrub or small tree often growing 15 to 30' high and larger. National champion is 30' by 38' in Porterville, CA. Several years past, while jogging on some back roads near Portland, OR, I noticed the plant in abundance. This was August and the dusty-coated, blue-black fruits were dripping from the plants. Fruits make good jam, jelly, pie and wine. The yellowish white flowers occur in convex, 5-rayed, 4 to 6" wide cymes in May to July. Have not seen on East Coast but for an elder collector could be worthwhile. Morton Arboretum reported that the species had not performed well. British Columbia, east to Montana and Utah. Cultivated 1850. Zone 5 to 7.

***Sambucus nigra* L.** — Common or European Elder
(sam-bū'kus nī'gra)

LEAVES: Opposite, compound pinnate, 4 to 12" long, leaflets 3 to 9, usually 5, short-stalked, elliptic to elliptic-ovate, 1 1/2 to 5" long, 3/4 to 2" wide, acute, sharply serrate, dark green above, lighter and sparingly hairy on the veins beneath; of disagreeable odor when bruised.

Sambucus nigra, European Elder, is a large, multi-stemmed shrub or tree ranging from 10 to 20'(30') high. The foliage is dark green in summer and of a disagreeable odor when bruised. Flowers are yellowish white, of a heavy odor, and borne in 5 to 8" diameter, 5-rayed, flat-topped cymes in June. The fruit is lustrous black, 1/4" diameter, September. There are numerous cultivars associated with this species including white-variegated, yellow- and purple-leaved, cutleaf, yellow-fruited, and edible commercial clones. I counted 43 in the RHS Plant Finder 2007–2008. The Strybing Arboretum, San Francisco had several cultivars that were quite handsome. I have observed the species all over the British Isles and continental Europe growing along roadsides, in ditches and in open fields. Have observed in shady environments in Europe. Appears more shade tolerant than *S. canadensis*. Apparently it deserves the same weed status as *S. canadensis*.

CULTIVARS:

'Aurea'—Bright yellow new foliage that fades with time and heat.

Black Beauty® ('Gerda', PP 12,305)—Dark purple-black leaves, pink flowers, black fruits; each flower kissed pink at tips of lobes, white in center; 6 to 8' high, 10' in 8 years; raised by Horticultural Research International, East Malling, Kent.

Black Lace® ('Eva', PP 15,575)—More lacy, fern-textured, dark purple leaves, pale pink flowers, 6 to 8' high; origin as for Black Beauty®.

'Castledean'—Deep green leaves, shiny black stems; 6 to 8' by 5 to 6'.

'Laciniata' (f. *laciniata* (L.) Zabel)—Finely dissected, green leaflets not unlike those of *Acer palmatum* var. *dissectum* 'Filigree Lace'; wonderfully fine-textured shrub that attracted considerable attention from members of our European garden tours.

'Guincho Purple'—Described as more purple than 'Purpurea', however, I see little difference.

'Madonna'—Bright and marbled golden yellow leaves on a 6 to 10' shrub; in general leaves are bordered with a bright golden yellow margin.

'Marginata'—Leaflets initially margined yellowish white, fading to creamy white; this is a most handsome form and probably requires heavy root moisture and partial shade in the eastern-southeastern United States; 'Aureomarginata' is akin to the above except the leaflets are bordered with a yellow-golden border.

'Pulverulenta'—Splashed, marbled, speckled, and striped with white; certainly somewhat unstable and should be treated as a cut-back shrub in winter; about 4 to 5' high.

'Purpurea'—Probably should be listed as f. *purpurea* since several purple leaf forms are known; new shoots are bronze-purple and the flower petals are pinkish; color does not hold well in heat but for spring effect is worthwhile; the purple-foliaged variant appears to have been reported only from the British Isles; according to Nelson, *The Plantsman* 8(3):189–190 (1986), the original cultivar names 'Foliis Purpureis' and 'Purpurea' are no longer valid and the name 'Guincho Purple' is proposed.

'Wildwood Snowtip'—White-edged leaves, 8' high, Zone 3.

ADDITIONAL NOTES: All the above except 'Laciniata' are best cut back in late winter to encourage strong, highly-colored shoots. For shrub borders, they offer a different touch. I have seen abundant aphids on the Black Elder, much more so than on *S. canadensis*. Spider mites and aphids are particularly troublesome in hot weather. East Malling Research Station, England, had a breeding program and made crosses among 'Aurea', 'Guincho Purple', and 'Laciniata'. The progeny showed characteristics of the parents with Black Beauty® and Black Lace® representing the first introductions. 'Thundercloud' is a branch sport of Black Beauty® with pink flowers, purple foliage, to 10' high. All of these are rated better than 'Guincho Purple'. See *Acta Horticulturae* 320:6–8 (1992). A hybrid between *S. nigra* and *S. racemosa* was discovered in southern Sweden. The plant was intermediate between the parents in inflorescence shape, flower size, flower color, pith, and fruit. 'Allesso', 'Goldberre' (green-gold fruits), 'Haschberg' (large, sweet fruits), and 'Korsor' (dark blue fruits) are grown primarily for their fruit qualities. Europe, northern Africa, western Asia. Cultivated since ancient times. Zone 5 to 6(7).

***Sambucus pubens* Michx.** (*S. racemosa* subsp. *pubens* (Michx.) House according to GRIN) — Scarlet Elder, American Red Elder
(sam-bū'kus pū'benz)

LEAVES: Opposite, compound pinnate, 5 to 7 leaflets, ovate-oblong to oblong-lanceolate, 2 to 4" long, stalked, serrate, lustrous dark green, pubescent or sometimes glabrous below.

Sambucus pubens, Scarlet Elder, grows 12 to 25' high with a similar spread. The flowers are yellowish white, May, borne in a 5" long, ovoid to pyramidal panicle. Full flower May 28, 2005 on Deer Isle, ME; plants in close proximity to salt water. Have observed many times in the Great Smoky Mountains National Park, particularly on the road and near the summit of Clingman's Dome. Actually quite respectable in flower. The fruit is a red or scarlet drupe, 1/5 to 1/4" diameter, ripening in late June into July, quite effective. Birds eat the fruits.

Supposedly inedible for humans. White- and yellow-fruited forms are known. The buds are solitary, 4-scaled, brown and the stems are light brown with a brown pith. 'Dissecta' has deeply divided leaflets. 'Leucocarpa' with white fruits and 'Xanthocarpa' with butterscotch-colored fruits are described.

I have not yet made their acquaintance. Found in rocky woods from Newfoundland to Alaska, south to Georgia and Colorado. Appears to require a cooler climate for best performance. Handsome plant in fruit and certainly worth leaving if native. Introduced 1812. Zone 4 to 6. It is closely allied to *S. racemosa* and now considered a variety.

***Sambucus racemosa* L.** — European Red Elder
(sam-bū'kus ra-se-mō'sa)

LEAVES: Opposite, compound pinnate, 6 to 9" long, 5 to 7 leaflets, ovate or elliptic to ovate-lanceolate, subsessile, 2 to 4" long, 3/4 to 1 3/4" wide, acuminate, sharply, coarsely and regularly serrate, lustrous dark green, glabrous on both surfaces.

Sambucus racemosa, European Red Elder, grows 8 to 12' high and has flowers and fruits similar to *S. pubens*, the fruits usually more tightly packed on the infructescence. 'Redman' is a heavy fruiting selection with finely dissected leaves. 'Sutherland Gold' ('Sutherland Golden') has golden yellow, finely-cut leaflets; leaflets more finely dissected than 'Plumosa Aurea'. This appears to be a good plant for northern gardens. I have observed it at University of Minnesota Landscape Arboretum where it showed good vigor. 'Tenuifolia' forms a mound of arching branches with finely divided, fern-like leaves. This, too, is a beautiful form but I do not know its adaptability to hot, dry conditions. It is not a strong grower. 'Plumosa Aurea' is a handsome form with finely cut leaflets and bright yellow new leaves that mature to green. This form is common in Europe and is frequently cut to the ground in late winter to encourage vigorous shoots. Interestingly, I saw the plant in June at Sissinghurst and it literally jumped out and grabbed me. On a September visit, I had trouble locating the same plant; the yellow coloration had completely dissipated. 'Plumosa' has large leaflets up to 5" long by 1 1/4" wide and the serrations reaching halfway to the midvein. This is a green leaf form. 'Goldenlocks' ('Golden Locks') from Canada is a dwarf form, to 30", with golden, finely cut-leaved foliage; have read 4 to 5' by 4 to 5' size. 'Goldfinch' is an oval-rounded, vigorous shrub with deeply divided yellow foliage; grows 10' by 6 to 8'; described as Zone 4 to 9 but that is simply untenable in Zones 7 to 9. 'Chedglow' and 'Crüg Lace' are listed in RHS Plant Finder 2007–2008. Native to Europe, western Asia. Cultivated 1596. Zone 4 to 6 or 7.

***Santolina chamaecyparissus* L.** — Lavender Cotton
(san-tō-lī'na kam-e-sip-a-ris'us)

FAMILY: Asteraceae

LEAVES: Alternate, pinnate, evergreen, 1/2 to 1 1/2" long, 1/8" or less wide, with short-oblong-obtuse, 1/24 to 1/12" long segments, whitish tomentose; strong aromatic odor when bruised; easily identified by virtue of subshrub nature and silvery gray-green foliage.

SIZE: 1 to 2' high, spread 2 to 4'.

HARDINESS: Zone 6 to 9.

HABIT: Evergreen subshrub forming a broad mound; almost cushion-like when properly grown.

RATE: Slow.

TEXTURE: Fine.

LEAF COLOR: Silvery gray-green through the seasons, a bit off-color in winter.

FLOWERS: Perfect, button-shaped, 1/2 to 3/4" diameter, yellow heads cover the plant like lollipops; usually in June–August; borne on 4 to 6" long stalks above the foliage; quite showy but should be removed after they fade; no ray florets present; apparently flowers set on new growth of season.

FRUIT: Achene, not important.

CULTURE: Transplants readily from containers; adaptable but prefers relatively dry, low fertility soils; will grow in pure sand; in excessively fertile soils becomes rank and open; full sun; prune after flowering or just about anytime during growing season to shape the plant; displays some salt tolerance.

DISEASES: Foliar blight caused by *Rhizoctonia solani* was reported; also root rot caused by *Phytophthora tentaculata*.

LANDSCAPE VALUE: Quite a tough plant; have observed it used in a multiplicity of sites from pure sand on Cape Cod to heavy clay in Illinois; excellent in mass or for low hedge or border; works well in rock walls or rock gardens; have grown this along with *S. virens* (now *S. rosmarinifolia*) in Urbana, IL and the Green Santolina did not prove as cold hardy; both are beautiful and elicit a positive response from the public; functional for repelling insects (see www.marcuciogardens.com).

CULTIVARS:

'Lambrook Silver'—Leaves silver-tinted; lemon-yellow flowers.

'Lemon Queen'—Compact-mounded, gray foliage, 2' by 2'; pale lemon flowers.

'Little Ness'—Smaller, compact.

'Nana' (var. *nana*)—Perhaps catchall term for compact forms; listed by RHS Plant Finder as a legitimate taxon.

'Plumosus'—Lacy, silver-tinted foliage.

'Pretty Carol'—Compact, gray foliage, grows to 16" high; creamy-yellow flowers all summer.

'Sant101' (PP 15,201)—Described as prostrate-mounding with gray-green to green finely dissected foliage and golden yellow flowers; considered a hybrid of *S. pinnata* subsp. *neopolitana* and 'Lemon Queen'; selection made in 1998 by Virginia McNaughton, New Zealand.

'Small-Ness'—A very dwarf form with gray-green leaves and butter-yellow flowers.

'Weston'—Dwarf, to 6" high, leaves bright silver.

PROPAGATION: Seeds germinate readily; cuttings can be rooted about anytime; very important to keep medium on the dry side; too much moisture spells failure.

ADDITIONAL NOTES: Wonderful for foliage and flower effect. In our Zone 7 Georgia garden the two species tend to melt out over time. Still worthwhile cultivating. About 18 species are cataloged from the Mediterranean regions. Flower is used in folk medicine for its anti-spasmodic, -inflammatory, -septic, -microbial, and digestive properties. See *J. Natural Products* 49:1143–1144 (1986).

NATIVE HABITAT: Southern Europe. Cultivated 1596.

RELATED SPECIES:

***Santolina rosmarinifolia* L.** (formerly *Santolina virens* Mill.) (san-tō-lī'nā rōs-ma'rīn-i-fō-lī-a), Green Santolina, is essentially a "dead ringer" for the above species except for the deep green, glabrous foliage and slightly more compact growth habit. Leaves are a degree longer (to 2"). The bright yellow, 3/4" diameter flowers borne on 6 to 10" long stalks are highlighted against the rich green foliage during July. In full flower on May 30 in the Dirr garden. Can be used in the same fashion as *S. chamaecyparissus*. Not as hardy as *S. chamaecyparissus*; requires same cultural manipulations. I have grown this a number of years and generally cut it back after flowering when it tends to open up and become floppy. 'Lemon Fizz' has consistent golden foliage with yellow flowers, from Pearce's Nurseries Pty Ltd., New South Wales, Australia; see *Plant Varieties Journal* 9(2):19–20 (1996). 'Primrose Gem' has pale primrose yellow flowers, thread-like leaves, 12" high. Southern Europe. Cultivated 1727. Zone 7 to 8(9).

***Sapindus drummondii* Hook. & Arn.** — Western Soapberry
(sa-pin'dus drum-mon'dē-ī)

FAMILY: Sapindaceae

LEAVES: Alternate, compound and even pinnate, 10 to 15" long, 8 to 18 leaflets, each short-stalked, obliquely lanceolate, 1 1/2 to 3 1/2" long, 1/2 to 1" wide, acuminate, off-set base, entire, lustrous medium green, glabrous above, pubescent beneath, each leaflet slightly curved or sickle-shaped not unlike pecan; rachis has no margin (wing).

BUDS: Globose, gray, sometimes superposed, about 1/8" high, 1/8" wide, with 2 bud scales visible, pubescent.

STEM: Stout, angled due to decurrent ridges, dirty gray, covered with short pubescence, leaf scars orbicular to shield-shaped, large; pith—white, solid.

SIZE: 25 to 30' high with a similar spread, have seen 40 to 50' specimens; national champion is 59' by 39' in Johnson, KS.
 HARDINESS: Zone 5 but best in Zone 6 to 9.

HABIT: Single-stemmed or low-branched tree with a broad-oval to rounded crown similar to *Koelreuteria paniculata*; makes a rather graceful small shade tree.

RATE: Medium.

TEXTURE: Medium.

BARK: Shallowly furrowed, develops platy or scaly condition, as these fall they create a patchwork of gray-brown, orange-brown to reddish brown.

LEAF COLOR: Glossy medium green in summer, deep yellow-gold in fall; excellent fall color.

FLOWERS: Yellowish white, about 1/5" across, borne in loose, 6 to 10" long, pubescent, terminal, pyramidal panicles in May to June; apparently there is an initial growth flush and with increasing day length the terminal portion turns reproductive.

FRUIT: Subglobose, 1/2" diameter, translucent, yellow-orange drupe that ripens in October; remains on tree through winter and into spring but the flesh may turn black; the seeds are black, rounded, 1/4 to 1/3" wide, with one (sometimes 2 to 3) in each fruit; a single 30' high, 40' wide tree resides in Athens that sets prodigious quantities of fruit every year; *Sapindus drummondii* is supposedly unisexual and for argument's sake I know this one tree is female; the question then arises as to the source of pollen for effective fruit set unless fruiting is parthenocarpic; Rehder mentions that the genus, not this particular species, is polygamous, so it is possible that the Athens tree is polygamo-dioecious with sufficient pollen supplied by the male flowers.

CULTURE: Easily transplanted, adaptable to varied soils and is native to infertile, dry soils throughout portions of the Southwest; extremely tolerant of urban sites and should be utilized more widely; wood is close-grained and strong, making the tree very wind resistant; seedlings may be objectionable.

DISEASES AND INSECTS: None serious, appears trouble-free as leaves are as clean in October as when first emerging in spring.

LANDSCAPE VALUE: Excellent choice for dry soil areas in South and Southwest; should be considered for use in urban situations; recommended as a shade and ornamental tree in dry areas of country; have reservations about recommending it for patio or street use because of the fruit litter; remember picking fruits off the ground in December at Missouri Botanical Garden; much better tree than *Melia azedarach*; observed as a thriving street tree in Wichita, KS; have witnessed numerous seedlings germinating in the vicinity of the Athens tree.

CULTIVARS:

'Narrow Leaf'—Described as having narrower foliage than typical for the species, offered by Louisiana Nursery.

PROPAGATION: The seeds have been described as doubly dormant and two hours scarification in sulfuric acid followed by 90 days at 40°F is recommended. I collected seed, removed the fleshy fruit wall by soaking, followed by extraction in a blender; the seeds were then placed in moist peat in poly bags at 41°F. After 54 days radicles had emerged in cold stratification. At this time the seeds were planted and about 95 out of 100 germinated. Seeds that received no cold treatment were also sown but only 2 to 3 seedlings emerged. Another test was conducted and it became evident that 30 days was sufficient time to induce some radicles to emerge. Based on the work I estimate 45 to 60 days cold to be sufficient. No scarification is necessary. Cuttings have also been rooted when collected in May-June, treated with 16,000 ppm IBA talc preparation; takes 5 to 6 weeks for rooting. In Kansas work, early June cuttings rooted equally well with a 10,000 to 30,000 ppm treatment.

ADDITIONAL NOTES: Generic name is derived from the nature of the fruits. When crushed in water they develop a lather. The West Indian natives used the saponin-rich fruits of *S. saponaria* L., Soapberry, as a soap substitute.

Occasional sightings of *S. mukorossi* Gaertn., Chinese Soapberry, with larger leaves, 8 to 12 leathery leaflets; larger flowers, greenish yellow; and glossy orange-brown, 4/5" diameter fruits; grows 40 to 50' high. Japan, Taiwan, China to India. Although listed as Zone 9 is growing in Raleigh, NC and Jungle Gardens, Avery Island, LA; will never become a commercial item. A variegated selection is known.

Have experienced native stands of *S. drummondii* in western Oklahoma growing in a relatively dry, harsh environment. Holds up well to the heat. A fruitless form would prove a valuable urban tree.

NATIVE HABITAT: Southern Missouri, Kansas, New Mexico, and Arizona to Louisiana, Texas and northern Mexico. Cultivated 1900.

Sarcandra glabra (Thunb.) Nak.

(sar-kan'dra glā'bra)

FAMILY: Chloranthaceae

LEAVES: Opposite, simple, evergreen, 4 to 6" long, 1 1/2 to 2 1/4" wide, oblong or ovate-oblong, acuminate, sharply and coarsely serrate, serrations appearing gland-tipped, lustrous dark green, veins prominent, glabrous, flat green below; petiole—1/4 to 1/2" long.

BUDS: Imbricate, green with red tinge, free at ends of scales, 1/4" long.

STEM: Terete, green, brownish red in winter, glabrous, swollen and flattened at nodes; pith—large, excavated, green.

Sarcandra glabra has received considerable attention from southern plantmen because of its lustrous evergreen foliage, mounded habit and bright red fruits that persist through winter. Habit is rounded-mounded, with size ranging from 1 to 3' high and wide. The small, yellowish flowers occur in small, terminal, simple to few-branched spikes in May. The 1/4" diameter, globose, fleshy, orange-scarlet drupes ripen in September–October and persist into spring of the following year. Container-grown plants are readily transplanted. Prefers moist, acid, organic, woody soil in partial shade. Will discolor/burn in excess sun and winter wind. I have grown the plant and it suffered foliar burn at 15°F in the winter of 1996–97 yet flowered and fruited on new growth of the season. Raulston reported outright kill in Raleigh in the winter of 1993–94. Apparently an important plant in Chinese medicine. I have seen *Sarcandra glabra* offered at the health food store. An aside, I have yet to take any. 'Flava' is a yellow-fruited form. 'Golden Treasure' has bright golden-orange-yellow berries in terminal panicles, Ted Stephens, Nurseries Caroliniana introduction. Beautiful purple-bronze-green foliage selection that was introduced from Japan. Common in Japan into Korea, Taiwan, China, India and Malaysia. Occurs naturally as an understory plant, often near streams. Zone 8 to 9.

*Sarcococca hookeriana* Baill. — Himalayan Sarcococca, Sweetbox

(sar-kō-kōk'a hook-er-ē-ā'na)

FAMILY: Buxaceae

LEAVES: Alternate, opposite, subopposite, simple, evergreen, coriaceous, lance-oblong to narrow-lanceolate, 2 to 3 1/2" long, 1/2 to 3/4" wide, slender-pointed, cuneate, lustrous dark green, glabrous, entire; petiole—1/3" long.

STEM: Slender, green, slightly pubescent, foul smelling when bruised.

SIZE: 4 to 6' high and wide, will spread by suckers to form a colony.

HARDINESS: Zone (5)6 to 8.

HABIT: Dense, evergreen shrub that forms a mounded outline, spreading by rhizomes to produce a colony.

RATE: Slow to medium.

TEXTURE: Medium-fine.

LEAF COLOR: Generally lustrous dark green although some plants have lighter green foliage; in English gardens especially on chalky or high pH soils, in a more exposed location, foliage is lighter green.

FLOWERS: Apetalous, unisexual, 1/2" long, white, actually off-white, fragrant, in the leaf axils, the female flowers below the male flowers, male with pink anthers, female with 3 stigmas, may open in fall but usually in March–April (February–March, Athens), essentially unnoticed as they occur under the foliage, only the sweet fragrance advertises their arrival.

FRUIT: Globose, 1/4 to 1/3" wide, shiny black drupe that persists into winter, not particularly showy and literally visible only then the leaves are parted.

CULTURE: Transplant from containers into loose, acid, high organic matter, moist, well-drained soils; will tolerate higher pH soils but does not appear as prosperous; partial shade to shade, will become off-color in full sun; appears to tolerate polluted atmospheric conditions; once established displays high drought tolerance.

DISEASES AND INSECTS: None serious; never observed insect or disease problems.

LANDSCAPE VALUE: Nowhere common but at its

best a worthy evergreen ground cover (var. *humilis*) that offers handsome foliage, and fragrant flowers; stoloniferous nature is not aggressive and can be kept in bounds; Longwood Gardens used it (var. *humilis*) along a path above the rock garden with *Cornus florida* planted on either side, makes an excellent combination; the true species is rare and my first genuine introduction occurred at Wisley Gardens; the species is larger and more robust than var. *humilis* (the typical representative of the species in this country); in late March 1996, I visited Blackthorn Gardens, Kilmeston, England and met Robbie and Sue White the owners and noted breeders of *Helleborus*; I spied the true *S. hookeriana* and asked Mr. White if he would sell a plant; he noted that he only had two plants and was unable to part with any; when paying for other purchases at the checkout, the attendant handed me a plant of *S. hookeriana*, no charge; the mark of all true plantsmen—if there are two, then one is shared.

CULTIVARS:

var. *digyna* Franch.—More compact than *S. hookeriana*, perhaps 2 to 3' high and wide, at least plants I have seen, with greenish shoots and narrow-elliptic to oblong-lanceolate lustrous green leaves about 1 3/4 to 3" (4 1/2") long, 1/2 to 1" wide, petiole—1/8 to 2/5" long; at Hillier, 4' tall plant was noted, February 19, 1999; the key difference is the presence of two styles (i.e. *digyna*) compared to 3 for the species; flowers are fragrant; plant is more hardy than *S. hookeriana* but less hardy than var. *humilis*; produces black fruits; it is easily rooted from cuttings as described below; in 1996, I collected 'Purple Stem' with purple-tinted young stems; the flowers are extremely fragrant and were in full flower in late February 1998 in the Dirr garden; leaves not as dark green as *S. hookeriana*; western China, introduced 1908.

var. *humilis* Rehd. & Wils. (GRIN listed var. *humilis* as a synonym of var. *digyna*; based on numerous observations as well as growing the plants in my garden, I believe the taxonomist has flipped.)—Often treated as a separate species but current thinking provides varietal status; this is the best of the *Sarcococca* species for northern gardens because of cold hardiness; at -3°F this species was unfazed while *S. hookeriana*, var. *digyna* and *S. confusa* were virtually defoliated in the piedmont of Georgia; variety *humilis* grows (12") 18 to 24" high, is stoloniferous, smaller in all its parts than *S. hookeriana*, and is black-fruited; noted plants 2 to 3' high at Wakehurst, April 18, 1999; native to western China, introduced 1907; Zone (5) 6 to 8.

var. *humilis* 'Sardid1' (PP 19,942, CBRAF)—More vigorous, spreading groundcover than the variety, fuller and denser; typical, fragrant white flowers; disease and deer resistant; 18" by 36"; Zone 5; introduced by Sidhu & Sons Nursery, Canada.

var. *humilis* 'Sarsid2' (PP 19,951, CBRAF)—Upright form with large dark green leaves and fragrant white flowers; 24" by 36"; Zone 5; introduced by Sidhu & Sons Nursery, Canada.

'Schilling' ('Schillingii' in RHS Plant Finder 2007–2008; considered illegitimate since latinization of cultivar names is now taboo)—Good looking form, 3' by 6'; abundant flowers; collected by Tony Schilling in Nepal (accession 2083); observed at Wisley, February 18, 1999.

PROPAGATION: Seeds will germinate without pretreatment. Collected fruits of *S. confusa* in March 1997, removed pulp, sowed seeds with germination 8 to 10 weeks later; seedlings were planted in Dirr garden in fall 1997. One of my favorite group of shade-loving plants and I always thought that breeding offered opportunities for improved growth habits. Have grown hundreds of seedlings of *S. confusa*, *S. hookeriana* (many different foliage types), *S. orientalis* and *S. ruscifolia* without any noticeable variation. Almost like vegetative propagation and I suspected apomixis. A reference stated that *S. humilis*, *S. ruscifolia*, *S. saligna* and *S. prunifolia* were listed as apomicts. Might mention that *S. prunifolia* has a long acuminate apex, the entire leaf willow-like, but lustrous dark green. Have only observed at Hillier. Certainly the species as I know them are phenotypically unique. I see no evidence in hybrid intermediate characteristics in any of the seedlings I have grown. Incidentally, two-year-seedlings develop flower buds. Cuttings of all species root readily. Have collected cuttings of variety *humilis* in November and February, 3,000 ppm IBA-quick dip, peat:perlite, mist with 100% success. The root systems were profuse. Suspect cuttings can be rooted year-round if shoots are firm.

Sarcococca hookeriana
var. *humilis*

ADDITIONAL NOTES: Years past I attempted to separate the various species and varieties, a feat which often distills to the fruit colors and number of styles. Enjoyed the academic chase but still am unable to easily separate the two varieties of *S. ruscifolia*. See Dirr, *Nursery Manager* 10(5):24, 26 (1994).

A revision of the genus appeared in *Botanical J. Linnean Soc.* 92:117–159 (1986). The genus comprises 11(14?) species distributed in southeast Asia from Afghanistan through the Himalayas to southeast Tibet, Assam, Upper Burma (today's Myanmar), China southwards to India, Sri Lanka, Thailand, and beyond. Interestingly, the work does not recognize *S. orientalis* (which see), a species that is morphologically and garden-wise unique from the others.

Have always admired *Sarcococca* and during the 1999 sabbatical in England, made 57 notations relative to size, foliage, fruit, condition; many threaded into this new edition.

NATIVE HABITAT: Western Himalayas and Afghanistan. Cultivated 1884.

RELATED SPECIES:

Sarcococca confusa Sealy
(sar-kō-kōk'a con-fū'sa)

LEAVES: Alternate, simple, evergreen, leathery, 1 1/4 to 2 1/2" long, 1/2 to 1" wide, elliptic, elliptic-lanceolate to obovate, long obtuse to acute, obtuse to cuneate, entire, lustrous green above, light green below, surface undulating; petiole—1/4" long.

Sarcococca confusa forms a 3 to 5' high and wide, densely branched, evergreen shrub. A 4 1/2' high plant grew at Longstock, February 20, 1999. The flowers are sweetly scented and based on olfactory comparisons more fragrant than *S. hookeriana*. They occur in late February–early March in Zone 7. The female flowers have either 2 or 3 stigmas. Fruits turn red and finally glossy black at maturity. Where well-grown this is a handsome plant but is considerably less cold hardy than var. *humilis* and should only be grown in Zone (7)8. More cold hardy than given credit by this author as plants have withstood 7°F without foliar injury while leaves of *S. ruscifolia* in the same garden area were browned. Known only from cultivation and was apparently collected by Wilson in about 1908. Reproduces true-to-type from seed and every seedling I grew exhibited foliage identical to the maternal source. This species is now more common in southeastern nurseries and has a great future because of its superb foliage, fragrant flowers and tenacity. In the Dirr garden, I planted several seedlings in a container and, except for *occasional* watering and fertilizing, they lived for five years. The species is unbelievably *drought* tolerant; almost unkillable. China. Introduced 1916. Considerable leaf kill on a large plant in the Coker Arboretum, UNC, February 6, 2005. Quite content in shade in Washington, NC.

Sarcococca orientalis C.Y. Wu
(sar-kō-kōk'a ôr-i-en-tā'lis)

LEAVES: Alternate, simple, evergreen, leathery, 1 1/2 to 3" long, 1/2 to 1 1/4" wide, acuminate, cuneate, 3-veined at base, entire, glabrous, lustrous dark green; petiole—about 1/4" long.

STEM: Flat olive-green, covered with short pubescence, stouter stemmed than most *Sarcococca* species, malodorous when bruised; pith-green, solid, ample.

Sarcococca orientalis offers larger, to 3" long, lustrous dark green leaves and early winter flowering, late December to early February in Dirr garden; on occasion, finished flowering before *S. confusa* started. Flowers are larger than those of *S. hookeriana*. Flowers from the axils of the leaves with 2 to 5 buds on a short, crooked stalk. Males with pink-blushed anthers and sepals, females with 2 stigmas. Fruits are shining black at maturity. In the Dirr garden, plants have performed well and are cold hardy to at least 7°F. At least one reference (*RHS*) noted that the species is not different than *S. h.* var. *digyna*. Garden evaluations tell a different story. Grows 2 to 4' high and develops suckering colonies. This is a superb garden plant, possibly the best for the Southeast (Zone 6 to 7(8)), because of the leathery, lustrous dark green, flat-surfaced (planar) leaves that hold the color in winter. Also, the habit is tighter, denser, more uniform than *S. confusa*. I received my first plant from Ted Stephens and multiplied it 1,000-fold, sharing with all who would take. Few refused. In England, measured 3' (Liss Forest Nursery), 3 1/2' (Hillier) and 4' high (Wakehurst) plants. See Lancaster, *The Garden* 119(1):16–17 (1994), for history of introduction and characteristics. Eastern China. Introduced 1980 by Roy Lancaster. Zone 6 to 8(9).

***Sarcococca ruscifolia* Stapf.** — Fragrant *Sarcococca*

(sar-kō-kōk'a rus-ki-fō'lē-a)

LEAVES: Alternate, simple, evergreen, broad ovate, 1 to 2 1/2" long, half as wide, acuminate, rounded, perhaps cuneate, 3-nerved at base, glabrous, lustrous dark green above, lighter beneath; petiole—1/8 to 1/4" long.

Sarcococca ruscifolia, Fragrant *Sarcococca*, is a 3' high and wide shrub with handsome foliage and milk white, fragrant flowers in the axils of the terminal leaves. Witnessed 6' high plant at Maurice Foster's garden, Kent, England. There are consistently 3 stigmas. Fruits are rounded, red, 1/4" diameter. A handsome plant but not sufficiently cold hardy for inclusion in gardens below Zone (7)8. Variety *chinensis* (Franch.) Rehd. & Wils. has longer, narrower leaves and is the common form in cultivation. The fruits are dark red and the female flowers have 3 stigmas. Foliage shape reminds of *Ruscus aculeatus*, only larger. At 7°F, foliage of the species and so termed var. *chinensis* were injured. I see essentially no difference between the species and the variety. Have not been as impressed with the *S. ruscifolia* types in our garden and the Southeast. Terribly confused with *S. confusa* but the latter has an undulating leaf surface and blunt apex compared to flat surface and extended, acuminate apex of *S. ruscifolia* and var. *chinensis*. Variety *chinensis* 'Dragon Gate' has narrow, shiny, long-pointed, rich green leaves. I brought a plant to our Georgia garden. Much more refined than the varieties, smaller in stature, probably 2'(3') at maturity, good-looking plant. Introduced in 1980 by Roy Lancaster. Have seen listed as 'Roy Lancaster'. Species native to central and Western China. Introduced 1901 by E.H. Wilson. Zone 7 to 9.

***Sarcococca saligna* (D. Don) Müll.-Arg.**

(sar-kō-kōk'a sal-ig'na)

LEAVES: Alternate, simple, evergreen, 3 to 5" long, 1/2 to 3/4" wide, linear lanceolate, pale green, glabrous.

Sarcococca saligna is a 2 to 4' high, rhizomatous-spreading, evergreen shrub with non-fragrant, green, male flowers, with yellow anthers, female with 3 stigmas, in March. Fruit is dark purple to black. The most handsome planting I observed grew at Caerhays Castle in Cornwall. About 3' high, rather wide-spreading and located by a wall and inside a gate. In the Dirr garden, it was killed to the ground every year and recovered during the spring–summer. Plant at the Raulston Arboretum, located in the lath shade house, limps along from year to year. Almost complete leaf browning (kill) in winter of 2004–2005 when observed on February 23, 2005 at Raulston. Certainly not commercial in eastern United States, perhaps on West Coast. Himalaya. Introduced 1908. Zone 9.

***Sarcococca wallichii* Stapf.**, (sar-kō-kōk'a wâl-lik-ē-ī), is a new acquisition

from Crûg Farm Plants, the leathery leaves, prominently veined, lustrous dark green, 2 to 3" long, 3/4 to 1 1/4" wide with 3 prominent veins, glabrous; petiole about 1/2" long, glabrous, light green, grooved on top. Sets abundant flower buds as young plant; buds evident by June–July. The fruits are black. Has proven easy to root and plants grow quickly. Know nothing about garden adaptability. If hardy, could be a great addition to the shade-tolerant genre. Grows about 5' high. Zone (7)8 to 9? Nepal.

***Sassafras albidum* (Nutt.) Nees** — Common *Sassafras*

(sas'a-fras al'bi-dum)

FAMILY: Lauraceae

LEAVES: Alternate, simple, ovate to elliptic, 3 to 7" long, 2 to 4" wide, acutish or obtuse, cuneate at base, bright to medium green above, glabrous and glaucous beneath, entire, mitten-shaped or 3-lobed; mittens occur in left and right hand models; petiole—1/2 to 1 1/2" long.

BUDS: Terminal, solitary, ovoid, sessile, about 4 to 6 exposed scales, green-tinged with red toward tip, 1/3" long; lateral buds small, divergent, green; terminal is the flower bud.

STEM: Bright yellowish green, often reddish where exposed to light, glabrous and glaucous; spicy-aromatic to both smell and taste; sympodial branching.

SIZE: 30 to 60' in height with a spread of 25 to 40', can grow larger; national champion is 77' by 67' in Daviess, KY.

HARDINESS: Zone 4 to 9.

HABIT: Pyramidal, irregular tree or shrub in youth, with many short, stout, contorted branches which spread to form a flat-topped, irregular, round-oblong head at maturity; often sprouting from roots and forming extensive thickets.

RATE: Medium to fast, 10 to 12' over a 5 to 8 year period.

TEXTURE: Medium in all seasons, very intriguing winter silhouette results from the sympodial branching habit.

BARK: Dark reddish brown, deeply ridged-and-furrowed, forming flat corky ridges that are easily cut across with a knife; bark almost a mahogany brown, handsome when mature.

LEAF COLOR: Bright to medium green in summer changing to shades of yellow to deep orange to scarlet and purple in fall; one of our most outstanding native trees for fall color; a sassafras thicket in October is unrivaled, at peak mid-October in Cincinnati, OH.

FLOWERS: Usually dioecious, yellow, weakly fragrant, developing before the leaves in April (late March, Athens), borne in terminal racemes, 1 to 2" long, apetalous, calyx about 3/8" long and wide, with 6 narrowly oblong lobes, 9 stamens in male; 6 and aborted in the female; flowers are actually quite handsome and can be readily distinguished in the early spring landscape.

FRUIT: Drupe, 1/2" long, dark blue, ripening in September but quickly falling or devoured by birds; the fruit stalk (pedicel) is scarlet and very attractive at close range; many people think the pedicel is the fruit.

CULTURE: Difficult to transplant; move balled-and-burlapped in early spring into moist, loamy, acid, well-drained soil; have observed chlorosis in high pH soils; full sun or light shade; in the wild often found in acid, rocky soil; has a strong tendency to invade abandoned fields and form dense thickets; as a pioneer tree it is somewhat intolerant and gives way to other species after a time; prune in winter; it is difficult to establish (transplant) from the wild because of the deep tap root and the few spreading, lateral roots; could possibly be container-grown and thus many of the transplanting problems would be alleviated; if a single-trunked tree is desired, be sure to remove the suckers (shoots) that develop; at Milliken Arboretum, balled-and-burlapped trees died to ground after transplanting but did regenerate shoots from roots; my thinking is the only way to succeed is via container-grown seedlings in smaller sizes; I don't remember the tree being offered in the average garden center; available via mail-order from specialty nurseries.

DISEASES AND INSECTS: Cankers, leaf spots, mildew, wilt, root rot, Japanese beetle, promethea moth, borer, sassafras weevil and scales have been reported. Observed extensive "shot-holing" in leaves caused by the Sassafras weevil which also feeds on *Magnolia grandiflora*.

LANDSCAPE VALUE: Excellent for naturalized plantings, roadsides, and home landscaping; with a little extra cultural effort one will be rewarded manifold; if native, leave it be.

PROPAGATION: Seeds exhibit strong embryo dormancy which can be overcome with moist stratification at 41°F for 120 days. Root cuttings collected in December and placed in 2:1:1; peat:loam:sand, produced plants.

CULTIVARS:

Variety *molle* (Raf.) Fern.—Leaves and stems with downy pubescence; witnessed at Hillier, meshed with *S. albidum* by GRIN.

ADDITIONAL NOTES: The bark of the roots is used to make sassafras tea and the “oil of sassafras” is extracted from the roots. Some concern that the extract from *Sassafras* is carcinogenic, but then what isn’t, since living can be construed as dangerous to one’s health. Interestingly, many medicinal attributes were attributed to the species. In Rockville, IN, an October festival offers numerous concoctions of sassafras including candy, tea, bread, et al. Certainly a great native plant and on numerous back roads throughout the eastern United States there is no more inspiring sight than a sassafras thicket in full flaming fall color. See Dirr, *Nursery Management and Production* 9(4):26, 28 (1993), for commentary on root cutting success and SpinOut™ treated container culture.

NATIVE HABITAT: Distributed from Maine to Ontario and Michigan, south to Florida and Texas. Cultivated 1630.

RELATED SPECIES

Sassafras tzumu (Hemsl.) Hemsl. (sas’a-fras sū’mū), Chinese Sassafras, came to our Georgia trials via Piroche Plants, Canada. The leaves are larger copies of our native species with similar fall color. Flowers, yellowish on naked stems in early March (Raleigh, NC). February 27, 2009 in full flower with what I nosed as a slight fragrance. Fruits have yet to develop. The growth rate is phenomenal, 3’ or more per year under good container culture. Tree develops wide-spreading, horizontally stratified branches. New leaves emerging in late March—early April 2007 killed by Easter freeze (about 26°F). Cold hardy in Raleigh; killed in western North Carolina at Fletcher. Zone 7 to 8, 9 on West Coast. China.

Sciadopitys verticillata (Thunb.) Sieb. & Zucc. — Umbrella-pine or Japanese Umbrella-pine (sī-a-dop’i-tis vē-ti-si-lā’ta)

FAMILY: Pinaceae, also listed as Taxodiaceae. Hart, *J. Arnold Arboretum* 68:269-307 (1987), suggested *Sciadopitys* should be in a separate family, Sciadopityaceae. Have observed its placement in Sciadopityaceae in more recent (2000 and later) publications.

LEAVES: Of 2 kinds, some small and scale-like scattered on the shoot, but crowded at its end and bearing in their axils a whorl of (10)20 to 30 linear flat leaves, each 2 to 5” long, 1/8” wide, furrowed on each side, more deeply beneath with a glaucous-green groove, dark glossy green, thick, almost prehistoric in appearance; the way the needles radiate around the stem creates an inside-out (wind-blown) “umbrella” effect.

STEM: At first green, later brown, glabrous, stout, flexible, striated, with prominent protuberances on stem.

BARK: Thin, nearly smooth, orangish to reddish brown, exfoliating in long strips, quite handsome but essentially hidden by the foliage.

SIZE: 20 to 30’ by 15 to 20’; can grow 60 to 90’ high; listed at over 120’ in the wild.

HARDINESS: Zone 5 to 7, not as prosperous in Zone 7 as further North, not quite hardy at the Morton Arboretum, Lisle, IL.

HABIT: Variable, from spire-like to broadly pyramidal tree in youth, with a straight stem and horizontal branches spreading in whorls, stiff and twiggy, the young branchlets with the leaves crowded at the ends; with age the branches become more pendulous and spreading and the whole habit loose; have also observed multi-stemmed versions.

RATE: Slow, extremely slow, perhaps 6” a year.

TEXTURE: Medium-coarse, one of the most interesting conifers for textural effect.

BARK: Rich orangish to reddish brown and exfoliating in long shreds or strips; handsome but generally unnoticed since hidden by foliage.

LEAF COLOR: Dark green and glossy above throughout the year, persisting about 3 years.

FLOWERS: Monoecious; female solitary, terminal and subtended by a small bract, male flowers in 1” long racemes.

FRUIT: Cones oblong-ovate, upright, 2 to 4” long, 1 to 2” wide, opening to 3” wide, scales with broad reflexed margins; cones are green at first, ripening to brown the second year, each scale bears 5 to 9 narrowly 2-winged, 1/3 to 1/2” long seeds.

CULTURE: Transplant balled-and-burlapped or container-grown plants, prefers rich, moist, acid soils and sunny, open locations; late afternoon shade is advantageous in hot areas; protection from wind is desirable; has not performed well in Zone 7; certainly not a commodity evergreen; needs careful siting.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: F.B. Robinson called it “a queer tree of odd texture; can be used as an accent or specimen”; L.H. Bailey termed it “one of the most handsome and distinctive of conifers”; for foliage effect as well as texture this conifer ranks among the best; could be integrated into a foundation planting, rock garden or border; the plant will grow in Zone 7 but prefers light pine shade; its unusual texture makes it a valuable addition to the list of needled conifers; Tripp and Raulston, *The Year in Trees*, noted a +120-year-old, 35' high specimen in the historic cemetery in Salisbury, NC. Great old plants in New England at the Arnold Arboretum, University of Massachusetts, Amherst, and Smith College, Northampton.

CULTIVARS: Several forms are described in the literature but are not common in commerce, even from specialty producers. Featured in *Conifers* by van Gelderen and van Hoey Smith are: ‘Ann Haddow’—yellow-variegated; ‘Aurea’—entire needle yellow; ‘Green Star’—dwarf with wider, dark green needles; ‘Ossorio Gold’—much like ‘Aurea’; ‘Picola’—broad-conical with dark green, 2" long needles, 16" high in 10 years; ‘Variegata’—with mixed green and yellow needles, offered by Gossler; and ‘Wintergreen’—narrow conical, small tree with rich green (almost blue-green) needle color, Sid Waxman introduction.

‘Jim Cross’—Dense, relatively compact form, with glossy dark green, slightly arching needles; foliage is densely borne and hides the stems and trunk from view; 10' high, 8' wide in 20 years; named after the late Jim Cross, Environmentals, Cutchogue, NY.

‘Joe Kozey’—A columnar form, deep green needles; Sid Waxman introduction.

‘Pendula’—Listed as a remarkable tree with pendulous branches; have not seen but would like to secure a plant.

‘Richie's Cushion’—Low dense mound, 3' by 6'; rich dark green needles; slow-growing.

Additional 17 cultivars listed in RHS Plant Finder 2007–2008; Stanley & Sons Nursery lists five forms in their 2007–2008 catalog; Bitner described 11 cultivars.

PROPAGATION: Either warm stratification for 100 days in moist sand at 63 to 70°F or cold for 90 days in moist, acid peat at 32 to 50°F have been recommended for inducing prompt germination. A combination of the two may be more effective. Seedlings kind of sit there for a while and look at you before deciding to “grow up.” Cuttings taken in January rooted 92% in sand:peat in 20 weeks after treatment with 100 ppm NAA for 24 hours. Cuttings from 7-year-old trees collected in January and treated with 20 ppm IBA rooted 70% in 8 months. In 32 weeks there was 43% rooting of untreated cuttings taken in August. See Waxman, *Proc. Intl. Plant Prop. Soc.* 28:546–550 (1978) for a detailed report on cutting propagation. In brief, Dr. Waxman noticed tremendous tree-to-tree rooting variability. The best rooting occurred when the cuttings were immersed in water and allowed to soak. There appeared to be a correlation between the amount of resin and rootability. Low resin correlated with high rooting. Hormones did not prove that critical. February–March and July–August were the best times. Interesting study, *HortScience* 30(1):133–134 (1995) that reported increased survival, callus development and rooting percentage when mycorrhizal fungi were added to a peat-based medium; rooting was 50% with fungi, 17% without.

NATIVE HABITAT: Restricted in a wild state to the Valley of the Kiso-gawa in central Hondo, and to Koya-san and its immediate neighborhood in east central Hondo; the best trees being found in steep, rocky, sheltered situations. Introduced 1861.

Securinega suffruticosa (Pall.) Rehd.

(se-cūr-in-ē'ga su-frū-ti-kō'sa)

FAMILY: Euphorbiaceae

LEAVES: Alternate, simple, elliptic or ovate to lance-ovate, 3/4 to 2" long, 1/3 to 1" wide, acute or obtuse, cuneate, entire, bright yellowish green, glabrous, petiole—1/8" long.

Securinega suffruticosa is a virtual unknown in American gardening and probably will remain buried in anonymity. I first saw the plant at the Missouri Botanic Garden, St. Louis, and was taken by the fresh green foliage and upright arching branches and rather dense constitution. Grows 6 to 8' high and wide. For use as a foliage mass, it has possibilities. The plant can be pruned in late winter to entice long shoot extensions. The greenish white flowers (July–August) and greenish capsules are not showy. Any well-drained soil and full sun suit it best. Will grow in partial shade. There was an 8' high plant at the Arnold Arboretum that developed soft yellow fall color. Optimum seed germination occurred after 3 months of cold stratification. See Koller, *Arnoldia* 53(2):21–23 (1993) for detailed information. Northeast Asia to central China, Taiwan. Introduced 1783. Zone (4)5 to 7(8).

Sequoia sempervirens (D. Don) Endl. — Redwood, California Redwood, Coast Redwood

(sē-kwoi'a sem-pēr-vī'renz)

FAMILY: Cupressaceae

LEAVES: Evergreen, needles spirally arranged on the terminal leader, about 1/4" long, slightly appressed to spreading, 2-ranked on the lateral shoots, 1/4 to 7/8" long, 1/20 to 1/8" wide, linear lanceolate or narrow oblong, sometimes falcate, with an abrupt point, lustrous dark green, almost bluish green above with two broad whitish stomatal bands below.

SIZE: Difficult to ascertain under landscape conditions on East Coast, perhaps 40 to 60'; in West 300'; currently tri-national champions that are 311' by 101' in Prairie Creek Redwoods State Park, CA, and 321' by 75' and 307' by 83' both in Jedediah Smith Redwoods State Park, CA; trees may live 500 to 700 years, and trees over 2000-years-old were recorded; can the reader imagine counting the rings?

HARDINESS: Zone 7 to 9.

HABIT: Imposing conifer, densely branched and gracefully pyramidal in youth, with time losing the lower branches and devoid of branches 50 to 100' from the ground with a still relatively narrow pyramidal crown.

RATE: Slow to medium in East, fast in West.

TEXTURE: Medium.

BARK: Exquisite on old trees being a rich red-brown and fibrous on the surface, with deep furrows and irregular ridges, described as ranging from 3 to 12" thick; I saw mature redwoods in Muir Woods, north of San Francisco, and walking in the shadows of these behemoths provided pause for reflection on man's coming and going; a living legacy that has held court over 30 generations of mankind and has never passed a negative verdict; yet man has attempted, albeit sometimes unintentionally, to destroy what is beyond his realm of comprehension, reasoning or appreciation.

LEAF COLOR: Dark green through the seasons, some forms show a distinct bluish green cast.

FLOWERS: Monoecious, male flowers, axillary and terminal with numerous spirally arranged stamens; female terminal with 15 to 20 peltate scales.

FRUIT: A 3/4 to 1 1/4" long, 1/2 to 3/4" wide, somewhat egg-shaped, dark brownish cone that ripens the first year; seeds reddish brown, 4 to 7 per scale, 1/6" long with 2 narrow wings along the side.

CULTURE: Generally container-grown in West Coast nurseries and should be transplanted as such; prefers moist, acid, deep, well-drained soils in areas of high atmospheric moisture; will never perform in eastern states like it does in native habitat or British Isles.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Only for specimen use as a noble conifer where room to ascend and spread is ample, a few of the compact cultivars are more suitable for smaller gardens; hold good green needle color better than many evergreens through winter in the Southeast.

CULTIVARS:

'Adpressa'—Has 1/4 to 3/8" long, loosely appressed needles, the young shoots are tipped creamy white (gray-green), often listed as a dwarf conifer but will produce vertical shoots and unless removed will become tree-like, may also be listed under names like 'Albospica' and 'Albospicata', may grow 4' by 4' in ten years; however, a 73' high tree has been described which indicates somebody forgot to prune; Raulston mentioned that this cultivar survived the -9°F winter while the species was killed; introduced before 1867 in France; was growing quite contently at Scott Arboretum, Swarthmore College; the 'Adpressa' that *Conifers* discusses is different from the above; my 'Adpressa' equates with *Conifers* 'Prostrata'.

'Aptos Blue'—Foliage is dark bluish green, secondary branches distinctly horizontal with tertiary branchlets pendulous.

'Cantab' ('Prostrata', 'Pendula Nana')—Arose as a branch sport of 'Prostrata' at the Cambridge Botanic Garden, semi-prostrate habit, distinct blue-green or gray-green, 1/2" long needles, about one-half as wide, unstable and will send up vertical shoots with needles akin to 'Cantab'; abundant confusion caused by this author due to the above discussion; in Great Compton Garden, England, there was a 30 to 40' high, compact pyramidal tree that is better suited to the small garden than the species; several authors described 'Cantab' as a reverted 'Prostrata'; Hillier has a 'Cantab' over 50' high, beautiful foliage like 'Adpressa', dense branches, conical habit.

'Filoli' ('Woodside')—Foliage distinctly blue, akin to Blue Colorado Spruce, *Picea pungens* Glaucā Group; beautiful 15 to 18' high plant at Atlanta Botanical Gardens December 27, 2006.

'Glaucā'—Foliage more blue-green than species, otherwise similar.

'Henderson Blue'—Makes a bushy, blue-foliaged tree; slow-growing; sets abundant cones.

'Los Altos'—Heavy-textured, deep green foliage on horizontal, arching branches.

'Majestic Beauty'™ ('Monty')—Densely set, blue-green foliage, pyramidal form with denser branching.

'Prostrata'—Dwarf form with spreading branches clothed with 2-ranked leaves, originated as a branch sport at Cambridge University Botanic Garden about 1951; Gossler reported that a 25-year-old plant was 6" high and 36" across, also mentioned pruning out the branch reversions ('Cantab') that try to assume control each year.

'Santa Cruz'—Strong pyramidal, cone-shaped tree, soft-textured, pale green needles, distinct horizontal secondary branches.

'Simpson's Silver'—Silvery blue needles; pretty glaucous, dusty blue foliage.

'Soquel'—Pyramidal habit, fine-textured dark green foliage, bluish on underside, holds good color in winter; growing contentedly in the JC Raulston Arboretum.

'Swarthmore Hardy'—Dark green needles; selected from a tree at Swarthmore College; possibly more cold hardy.

PROPAGATION: Seeds require no pretreatment. Cuttings of 'Santa Cruz' rooted 70% with 16,000 ppm IBA, 47% on 'Soquel' with 6,000 ppm IBA + 6,000 ppm NAA. Cuttings must be staked and pruned to develop a leader. Juvenility correlates strongly with rooting success, the younger the stock tree the higher the rooting percentage with or without hormone.

ADDITIONAL NOTES: Performs reasonably well on East Coast and 30 to 40' trees are occasionally encountered in the Southeast. Have grown several clones in the Georgia trials: one propagated from an Atlanta tree that prospered; another with the central leader dying.

NATIVE HABITAT: Confined to the fog belt along the Pacific Ocean from southern Oregon to California around San Francisco. Introduced 1843.

RELATED SPECIES:

Sequoiadendron giganteum (Lindl.) J. Buchholz., (sē-kwoi'a-den'dron jī-gan'tē-um), Big Tree, Sierra Redwood, Wellingtonia, is another West Coast giant growing 250 to 300' in the wild but much less, perhaps 60', under cultivation in the East. National champion is 274' by 107' in Sequoia National Park, CA. In England, numerous +100' high trees are common. The habit is dense and pyramidal-oval in youth, losing its lower branches with a narrow-pyramidal crown of foliage in the upper reaches at maturity. The bluish green needles vary in length from 1/8 to 1/2" and are usually awl-shaped and triangular in cross section, tapering from the base to a fine point. Needles point forward toward the apex and completely cover the stem and spiral in 3 longitudinal rows. Needles persist 3 to 4 years. Cones are 1 1/2 to 3" long, 1 1/4 to 2" wide, reddish brown at maturity, upright the first year, pendulous the second, the flattened seeds shining pale to yellowish brown, 1/4" long, with 2 broad wings, 5 to 9 per scale. The bark is spongy in texture and rich reddish brown. This species succeeds in the eastern United States and Longwood Gardens has a number of 30 to 40' high trees. The species withstands drier conditions than *Sequoia sempervirens*. Tyler Arboretum, Lima, PA had a 100' tall specimen. Also growing at Arnold Arboretum. Several cultivars are known but the most common is 'Pendulum' with an erratic leading stem that zigs, zags, arches, bends, dips and dives to form a piece of living sculpture. The secondary branches hang mop (mane)-like. The whole plant leaves much to the imagination. 'Hazel Smith' is a strong-growing, upright tree with bluish needles and greater hardiness; I have rooted it from winter cuttings with excellent success; received an Award of Merit from the Royal Boskoop Horticulture Society in 1993. Have grown 'Hazel Smith' in our trials and it slowly declined. 'Les Barres' is a better form than 'Glaucum' with bluer foliage, greater cold hardiness, and slower growing. 'Pygmaeum' is a compact, shrubby form, 2' high, 9' wide, may revert to the type. 'Requiem' is a more uniform, weeping form with a central leader and gracefully arching secondary branches. Many cultivars offered in European commerce. California in the Sierra Nevada Mountains at elevations of 4,500 to 8,000'. Introduced 1853. Zone 6 to 8. Have read that the species grows in Scandinavia and survived -22°F. My observations indicate this species is not as adaptable to the heat and humidity of the Southeast as *Sequoia sempervirens*.

Serissa japonica (Thunb.) Thunb. (formerly *S. foetida* (L. f.) Lam) — Yellow-rim
(ser-ē'sa ja-pōn'i-ka)

FAMILY: Rubiaceae

LEAVES: Opposite, simple, evergreen, semi-evergreen, deciduous, ovate to elliptic, 1 to 1 1/2" long, to 1/2" wide, acute, cuneate, entire, glabrous, deep green above, lighter below, with clusters of leaves in axils, virtually sessile.

STEM: Fine, gray, glabrous, malodorous when bruised.

Serissa japonica is a small, rounded, 3 to 4' high, fine-textured, evergreen shrub with dark green leaves and 4- to 6-lobed, 1/3" diameter, white, non-fragrant flowers in May–June.

Peak flowering occurs in May; my notes say May 17, 1995 which was an “early” spring. Mid May, 2009, in Athens. The plant has been growing on the Georgia campus for numerous years without an identity. It has survived -3°F and droughts too numerous to recount, all in the shadow and root competition of a 30 to 40' high *Quercus virginiana*. In Japan it is used as a hedging plant. Dr. Raulston succeeded with the plants at Raleigh and collected various cultivars for evaluation. Developed temporary insanity and tested the pink ('Rosea', 'Pink Swan'), double-flowered ['Plena' ('Flore-pleno')], more heavily variegated leaf ('Variegata') forms, and all were rendered objectionable by the cold. 'Cherry Blossom' has large, pink flowers and tiny, white-edged leaves. 'Kowloon' is a highly variegated form with 1/3 to 1/2 of leaf surface covered by a cream-yellow margin. 'Kyoto' is a compact clone with single, white flowers and tiny leaves. 'Mount Fuji' is compact with more heavily white-variegated leaves. 'Sapporo' is an upright form with smaller leaves that has proven cold hardy in our garden. 'White Swan' produces larger flowers and cream-edged leaves. 'Pink Mystic' and 'White Snow' are also listed. The major species form still standing (~4' high) in our garden is a propagule from the campus plant. In partial shade, it has prospered and is admired by visitors who want to know the identity. Bonnie and I have utilized the plant in containers where it provides handsome fine foliage texture and color (variegated margins). Adaptable and will withstand about any site conditions except permanently wet. Still has not “caught on” as an everyday garden plant. Its ironclad performance over my 30 years on the Georgia campus correlate with great adaptability. Southeastern Asia. Introduced 1878. Zone (6)7 to 9.

Shepherdia canadensis (L.) Nutt. — Russet Buffaloberry

(she-pěr'di-a kan-a-den'sis)

FAMILY: Elaeagnaceae

LEAVES: Opposite, simple, 1/2 to 2" long, 1/4 to 1" wide, elliptic to ovate, obtuse, dark green and sparingly scurfy above, silvery stellate pubescent below, often much of the pubescence is brown (brownish scales); petioles—1/8 to 1/6" long, stellate pubescent.

BUDS: Rather small, solitary or multiple, stalked, oblong, with 2 or 4 valvate scales.

STEM: Red-brown, scurfy, scaly, not spiny, nearly terete, rather slender; leaf scars half-round, minute, slightly raised; 1 bundle trace; pith—small, round, continuous.

SIZE: 6 to 8' high and as wide, varies from 3 to 9' high.

HARDINESS: Zone 2 to 6.

HABIT: Small, loosely-branched shrub of rounded outline, not the most inspirational landscape shrub.

RATE: Slow to medium.

TEXTURE: Medium in all seasons.

LEAF COLOR: Silver-green to gray-green in summer; upper surface green, lower silvery mixed with brown scales, like most members of the Elaeagnaceae does not color well in the fall.

FLOWERS: Dioecious, small, apetalous, yellowish, 1/6" across; in short axillary spikes or the pistillate often solitary, April to early May, not showy.

FRUIT: Drupe-like achene, yellowish red, insipid, ovoid, 1/6 to 1/4" long; effective in June and July.

CULTURE: Move as container-grown plants; easily grown and tolerates the poorest of soils; does well in dry or alkaline situations; prefers sunny open position; has the ability to fix atmospheric nitrogen.

DISEASES AND INSECTS: Several leaf spots, powdery mildew, and a rust have been reported but are not serious.

LANDSCAPE VALUE: Actually of no value where the soil is good and better shrubs can be grown; has possibilities along highways and other rough areas where poor soils, lousy maintenance, and salt are the rule, good plant for dry, high pH soils.

CULTIVARS:

'Rubra'—Red-fruited selection.

'Xanthocarpa'—Yellow-fruited type.

PROPAGATION: Seeds of both species have embryo dormancies and should be stratified for 60 to 90 days at 41°F ; the seed coats are hard and an acid scarification for 20 to 30 minutes proves beneficial. July cuttings of the yellow-fruited form treated with 8,000 ppm IBA-talc rooted 100%. Tissue culture and hardwood cuttings were successful with *S. canadensis* and *S. rotundifolia* Parry. Forty-seven percent rooting of *S. canadensis* occurred from May hardwood cuttings treated with 3,000 ppm IBA. See *J. Environ. Hort.* 9:218–220 (1991).

ADDITIONAL NOTES: I have seen both species, but only in arboreta or on campuses and was not intrigued by either. They are extremely cold- and drought-tolerant as well as alkaline soil adaptable and should be used in areas where these conditions prevail. For fruit set both male and female plants are required. Fruits are the usual late summer food for bears in the Front Ranges of Banff National Park, Alberta, Canada.

NATIVE HABITAT: Newfoundland to Alaska, south to Maine, Ohio, northern Mexico and Oregon. Introduced 1759.

RELATED SPECIES:

Shepherdia argentea (Pursh) Nutt. — Silver Buffaloberry
(she-pēr-di-a ār-jen'tē-a)

LEAVES: Opposite, simple, elliptic, 1 to 2" long, 1/8 to 5/8" wide, obtuse, entire, covered with silver or silver-brown scales, densely pubescent; petiole—1/4 to 1/2" long.

BUDS: Loosely scaly, 2-, 4- to 6-scaled, elongated, silvery to silvery brown, 1/4" long, densely pubescent.

STEM: Young—terete, silver tomentose; old—brown, bark flaking and appearing like an onion skin; pith—brown, excavated; spines 1 to 2" long, terminating leafy branches.

Shepherdia argentea, Silver Buffaloberry, is a thorny shrub, sometimes nearly tree-like, growing 6 to 10' high, although it may reach 18'. The foliage is silvery on both surfaces and much more gray in appearance than *S. canadensis*. The flowers and fruits (red or orange) are similar to the above species with only minor exceptions. The fruits of both species have been used for jellies. 'Sakakawea' has clean silver-green leaves, yellow to orange-red fruit, grows to 15' high, well-adapted to droughty, alkaline conditions, Zone 2 to 6, introduced by USDA Natural Resources Conservation Service at Bismark, ND, Plant Material Center. 'Xanthocarpa', a yellow-fruited form, is described in the literature. 'Goldeye' is a yellow-fruited type, could be a fancy name for 'Xanthocarpa'. Native to Minnesota and Manitoba to Saskatchewan, Kansas and Nevada. Introduced 1818. Zone 2 to 6.

Sinojackia rehderiana Hu — Jacktree

(sī-nō-ja'kē-a red-ēr-ē-ā'na)

FAMILY: Styracaceae

LEAVES: Alternate, simple, elliptic to elliptic-obovate, 1 to 3"(4") long, about 2/3's as wide, short acuminate, rounded, minutely serrate to entire, lustrous dark green and glabrous above, pubescent on veins below; petiole—1/4" long.

BUDS: Terminal—naked, foliose, brown, pubescent, 1/8 to 1/4" long, laterals—similar if not the same, stalked, another small bud sits above leaf scar at base of stalked foliose bud.

STEM: Slender, brown, pubescent, developing vertical fissures, becoming stringy; pith—green, solid.

Sinojackia rehderiana offers potential as a large shrub or small tree, probably 15 to 20' high at maturity. I have seen the plant at JC Raulston Arboretum in October and at that time the foliage was still dark green. Leaves emerge early, often in March in Zone 7. Fall color, yellow to bronze in early to mid November, Zone 7. The white, 1" wide, 5- to 7-petaled flowers occur in 3- to 5-flowered cymes at the ends of lateral shoots in April–May. A plant at the Arnold Arboretum was abundant with flowers on May 13, 1991. This particular plant was growing in partial shade. I have also seen plants in full sun that appear robust. A small plant in a semi-shaded corner of our garden has performed well. The woody drupe is 3/4" long and 1/2" across with a broad conical obtuse apex. Appears to thrive in full sun and well-drained soil. Propagation by June cuttings has been successful. Seeds are difficult. May have to mechanically break the endocarp. Plants of *S. rehderiana* have grown 20 to 30' high in southeastern gardens. The habit is often loose, open and multistemmed. Requires pruning, possibly staking, to develop central leader and dense canopy. Plants display heat and drought tolerance once established. Probably not mainstream but certainly attractive in flower and foliage. The flowers resemble white stars on slender stalks. Ideally site so passersby look up at the flowers. 'La Grima' is a more or less broad fastigiate form with the attributes of the species, while 'Linda

Carol' is a stiff, semi-weeping selection. Both introduced by Brian Upchurch, Highland Creek Nursery, NC and growing at Raulston Arboretum. 'La Grima' in full flower with the leaves on April 8, 2007 at Raulston, each flower with 6 to 7 petals and no fragrance. The brown fruits remind of upside-down acorns. Fall color is yellow to yellow-bronze. *Sinojackia rehderiana* is native to eastern China. Introduced 1930. Zone 6 to 8.

Also, *S. xylocarpa* Hu with smaller leaves, denticulate and rounded at the base, has crossed the author's path. Growth habit and size potential are similar. This species does not appear to have the same handsome foliage as *S. rehderiana*.

Sinowilsonia henryi Helms. — Henry Wilson Tree

(sī-nō-wil-sō-nē'a hen'ri-ī)

FAMILY: Hamamelidaceae

LEAVES: Alternate, simple, broad ovate, 4 to 6" long, to 4" wide, acuminate, semi-cordate, bristle-toothed, dark green, stellate pubescent below; petiole—short.

STEM: Brown, stellate pubescent.

Sinowilsonia henryi is strictly a collector's large shrub or small tree, 15 to 20' high, with large, handsome leaves and inconspicuous, apetalous flowers in terminal racemes. Monoecious with male flowers in 1 1/2 to 2" long catkins; female in racemes 1/2 to 1 1/2" long, extending to 6" in fruit. The fruit is ovoid, 2-valved, 3/4" long, woody capsule containing jet black seeds. This is a monotypic genus and I have seen the tree on just a few occasions, initially at the Edinburgh Botanic Garden. Imagine my excitement in October 2007 at Planting Fields Arboretum, Long Island, New York, where a 30' by 40' multi-stemmed tree accelerated my blood pressure to new highs. Relatively smooth gray bark, abundant fruits and a regal presence. Prefers woodland type soils. Named after the great plant explorer, E.H. Wilson. Central and western China. Introduced 1908. Zone 6 to 7.

Skimmia japonica Thunb. — Japanese Skimmia

(skim'i-a ja-pon'i-ka)

FAMILY: Rutaceae

LEAVES: Alternate, simple, evergreen, crowded at end of branches and appearing whorled, elliptic-oblong to oblong-obovate, 2 1/2 to 5" long, 3/4 to 2" wide, bright green upon emerging, finally dark green above, yellowish green beneath, entire, glabrous, dotted with pellucid glands, aromatic when bruised; petiole—short, 1/4" long, glabrous, reddish purple.

BUDS: Imbricate, covered with red scales, glabrous, 1/16 to 1/8" long.

STEM: Stout, green with an overcast of reddish purple, glabrous, spicy-fragrant when bruised; pith—ample, excavated, green.

SIZE: 3 to 4' with a similar spread; have seen plants 6' (Hillier, Wakehurst) and larger.

HARDINESS: Zone (6)7 to 8(9).

HABIT: Dense, rounded to haystack-shaped (dome-shaped), evergreen shrub of rather gentle garden proportions.

RATE: Slow.

TEXTURE: Medium.

LEAF COLOR: Arguably dark green, although often stands out as a light green when compared to other broadleaf evergreens.

FLOWERS: Dioecious, glossy red-maroon in bud, creamy white when open, weakly fragrant, each flower 1/3" across and borne in 2 to 3" long, 1 to 2" wide upright panicles; March–April (early April in Athens); flowers on male plants larger and more fragrant; selections have been made for this trait; peduncle and pedicels are glabrous and glossy reddish purple; almost more showy than flowers.

FRUIT: Only on female plant, bright red, 1/3" wide, globose drupe that ripens in October and persists into the following spring; fruit is borne at end of shoots in panicles described above and is very effective; about one male to 6 females is necessary for good fruit set.

CULTURE: Transplant from containers; prefers moist, acid, high organic matter soils although will supposedly thrive in chalky (limestone) soils; partial shade or full shade is beneficial especially in winter when foliage is apt to discolor; in northern areas provide some winter protection.

DISEASES AND INSECTS: Mites can disfigure foliage.

LANDSCAPE VALUE: Beautiful evergreen shrub of dainty proportions for use in foundations, planter boxes, mixed broadleaf evergreen plantings; although sold and grown in Zone 7, over my 30 years in Athens, I have yet to see a plant withstand the test of the southern landscape, simply languishes.

CULTIVARS: Many are known but to my knowledge none are particularly common in the United States; widely available in Europe and the RHS Plant Finder 2007–2008 listed about 50.

'Bronze Knight'—A male clone with flowers similar to 'Rubella', the leaves, however, more lustrous dark green and sharply pointed, leaves tinted red in winter.

'Magic Marlot' (PP 16,884)—Young leaves have yellow margins, maturing to cream; flower buds initiate cream in summer, bronze in autumn, dark pinkish red in winter; discovered in 1998 as a sport of *S. japonica* 'Marlot'; introduced by Jim Koot, Netherlands.

'Nymans'—Free-fruited form with oblanceolate leaves and comparatively large red fruits; may be the best fruited form but a male is required to insure fruit set.

'Ranso En' (PP 15,765)—Cream margined leaves; branch sport on *S. japonica* discovered by Noriaki Kogawa, Japan, and patented by Hines Nurseries, Irvine, CA.

'Rubella'—A male clone with large, 3" long, 2 1/2" wide at base panicles of red buds through winter, peduncle and pedicels deep shiny bronze-red, opening to 4-petaled white with yellow anthers in spring, very fragrant; leaves dark green, 3 to 4" long, petiole dark red; also listed as *S. reevesiana* clone and meshed with that species by GRIN.

'Ruby Dome'—Considered an improvement on 'Rubella' because it produces abundant pollen; have seen 'Ruby King' listed which sounds much like 'Ruby Dome'.

'Veitchii' ('Foremanii')—Vigorous form with broad-obovate leaves and large clusters of brilliant red fruits; flowers white; 2 to 3' by 2 to 3'; flowers usually female although bisexual flowers occur.

'Wakehurst White' ('Fructo-albo')—The proposed new name for the white-fruited cultivar previously termed 'Fructo-albo', see *Curtis's Botanical Magazine* 12(1):25–28 (1995).

PROPAGATION: Seeds when cleaned and sown germinate readily without treatment. Have collected fruits of *S. reevesiana* in fall, cleaned from pulp, sown, with germination in 3 to 4 weeks. Cuttings root quite readily when treated with 3,000 to 8,000 ppm IBA-talc; rooting should approach 100%.

ADDITIONAL NOTES: About four species are known along with a number of subspecies which at various times were elevated to species status. Beautiful plants in their forest incarnations but difficult to sustain in the East and South. Have observed terrific mite damage in the South. The best plants surface in the middle Atlantic States. The European literature is rich with cultivars and should be consulted. Twenty-three cultivars described in *Hillier Manual* 2002. I observed/photographed 12 cultivars during sabbatical 1999 with one of the largest collection at Wakehurst. In the United States, 'Rubella' is a common clone in commerce.

NATIVE HABITAT: China, Japan. Cultivated 1838.

RELATED SPECIES:

Skimmia laureola (DC.) Sieb. & Zucc. ex Walp. — *Skimmia*
(skim'i-a lâ-rê-ô'la)

LEAVES: Alternate, simple, evergreen, 2 1/2 to 4 1/2" long, 1 to 1 1/2" wide, oblong-obovate or oblong-elliptic, acute to short acuminate, cuneate to rounded, entire, glabrous, rich green above, aromatic when bruised; petiole—1/4 to 3/8" long, green.

Skimmia laureola, *Skimmia*, forms a compact, low-growing, handsome-foliaged shrub about 2 to 3' high and wide. The sweet-scented, creamy green flowers occur in lax, pyramidal, 4" long, 3" wide panicles in spring, although I saw plants in full flower in January in England. The fruit is purplish black but has not been seen on cultivated plants. Apparently all(?) forms in cultivation are male. 'Fragrant Cloud' is wide-spreading to 18" high with bright green leaves and abundant flowers. 'Kew Green' is a handsome male form with large panicles of greenish flowers, larger than normal and quite unusual, no trace of reddish pigment in flowers; leaves are large dark green and densely set. 'Kew Green' is listed as a cultivar of *S. ×confusa* N.P. Tayl. (*S. anquetilia* N.P. Taylor & Airy Shaw × *S. japonica*). Included in this grex are: 'Chelsea Physic' which is similar to 'Kew Green' but lower growing and with smaller leaves and smaller, 4" diameter, pyramidal inflorescences of creamy white, male; and 'Isabella' with bright red fruits. See *Kew Magazine* 6(4):159-162 (1989) for specifics on 'Chelsea Physic'. Probably only adapted to Pacific Northwest and have never seen the species in the eastern corridor. Some speculation that *S. laureola* as described by Bean from plants in Kew Gardens are, in fact, hybrids. Best rooting on July–August, followed by September cuttings. Himalayas. Cultivated 1868. Zone 7(?) to 9.

Skimmia reevesiana Fort.—Reeves *Skimmia*
(skim'i-a rêv'si-ā'na)

LEAVES: Alternate, simple, evergreen, lanceolate or oblong lanceolate, 1 to 4" long, 3/4 to 1" wide, acuminate, cuneate, entire, dark green above, light green beneath.

Skimmia reevesiana, Reeves *Skimmia*, is a low-growing, 1 1/2 to 2'(3') high and 2 to 3' wide, evergreen shrub. It tends to be more loose and open than *S. japonica*. The flowers are white, fragrant, bisexual, 1/2" diameter, parts in 5's, and produced in 2 to 3" long and wide terminal panicles. The oval to pear-shaped, 1/3" long, rich crimson fruits persist into winter. Because of the bisexual nature of the flowers, a lone plant will set fruit. It requires a rich, moist, acid soil. 'Chilan Choice' was introduced as a superior form by Wakehurst Place, England, grown from seed collected by Paul Meyer in 1979 in Taiwan. There is a variegated form with white-margined leaves. Also listed as *S. japonica* subsp. *reevesiana* (Fort.) N.P. Tayl. & Airy Shaw. China. Introduced 1849. Zone (6)7 and considered more cold hardy than *S. japonica*. Have observed beautiful plantings, almost ground-cover like, with dark green leaves and large clusters of shining cherry-red fruits. Appears more adaptable than *S. japonica* but seldom offered in everyday commerce.

Smilax L. — Green-brier

FAMILY: Liliaceae

A large group, about 200 species, of deciduous or evergreen, woody or herbaceous climbers, stems often thorny (prickly), twining and high climbing, forming an impenetrable tangle of green to brown, armed stems. The flowers are dioecious, greenish, yellowish, whitish, in axillary umbels. The fruit is generally a rounded berry, about 1/4 to 1/3" wide, blue, black or red.

The foliage, particularly on the evergreen types, is lustrous dark green; also leaves are often marked or splotted with lighter or darker markings. The evergreen types, particularly ***Smilax smallii*** Morong., (smī'laks smâ'ê-i), Bamboo Vine, Jackson Vine, are used for their shiny foliage in Christmas decorations. This species grows wild in the Southeast. It is essentially thornless and therefore easier to handle than most species.

Smilax rotundifolia L., (smī'laks rō-tun-di-fō'li-a), Horse-brier, Common Green-brier, is the species that many gardeners, hikers and unsuspecting daydreamers most frequently encounter. It is deciduous (tardily) to semi-evergreen (South) with 1 1/2 to 6" long, various shades of green with markings, ovate to sub-orbicular,

acute or cuspidate, rounded or cordate, petiole—1/4 to 1/2" long. The rounded green stems are armed with stout prickles. Fruits are 1/4" long, 1- to 3-seeded, bluish black berries. Nova Scotia to Georgia, west to Minnesota, Illinois and Texas. Introduced about 1760. Zone 4 to 9.

The two species discussed grow in quantity around Athens and I have largely eliminated the latter, while preserving the former, on our property. Both form tubers or rhizomes which have unbelievable regenerative prowess. I have observed 4 to 6' of growth in two weeks time from *S. rotundifolia*.

Smilax walteri Pursh., (smī'laks wâl'tēr-ī), Coral Green-brier, is similar to *S. rotundifolia* but produces red fruits. It also grows in wet soil areas and is distributed chiefly in the Coastal Plain from New Jersey to Florida and westward to Louisiana, central Arkansas and Tennessee. Seeds germinate without pretreatment when removed from the fleshy berry.

Smilax smallii

Smilax rotundifolia

Smilax walteri

Sorbaria sorbifolia (L.) A. Braun. — Ural Falsespirea

(sôr-bā'ri-a sôr-bi-fō'li-a)

FAMILY: Rosaceae

LEAVES: Alternate, pinnately compound, 8 to 12" long, 13 to 25 leaflets, 2 to 4" long, 1/2 to 1" wide, lanceolate to ovate-lanceolate, long acuminate, double and sharply serrate, usually glabrous or nearly so beneath, deep green above, subsessile; resembles mountainash foliage.

STEM: Young—usually green or pink, often somewhat downy, gray-brown when old and glabrous; pith—large, brown, continuous.

SIZE: 5 to 10' in height with a similar spread.

HARDINESS: Zone 2 to 7(8).

HABIT: Erect, rather coarse multi-stemmed shrub, with foliage similar to European Mountainash; spreads rapidly by suckers, forming colonies.

RATE: Fast.

TEXTURE: Many people say the texture is coarse but I feel if the shrub is properly pruned and maintained the texture is at worst medium in summer; tends toward coarseness in winter.

LEAF COLOR: Has a bronze to reddish tinge when unfolding gradually changing to deep green in summer; fall color is not effective; leaves out early and I have seen emerging leaves as early as late March in central Illinois.

FLOWERS: Perfect, white, 1/3" across; late June into July; borne in large, terminal, fleecy, 4 to 10" long, to 6" wide panicles; very effective and, in fact, outstanding in flower, flowers turn brown upon senescing; flowers occur on new wood of the season; this is true for all species.

FRUIT: Dehiscent follicles.

CULTURE: Transplants readily, very fibrous rooted, suckers and spreads profusely; prefers moist, well-drained, organic soil; tends to become dwarfed in dry soils; full sun or light shade; pH adaptable; prune in early spring before growth starts as the flowers are produced on current season's growth; cut off old flowers; relatively easy plant to grow, however, it is not widely known.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Excellent plant for the shrub border, for massing, grouping, might make a good bank cover as it freely suckers and spreads; is one of the first shrubs to leaf out in spring; needs considerable room to spread and is not suitable for small planting areas.

CULTIVARS:

'Sem' (PP 16,336)—Dense, compact, 3' high; new leaves copper-pink; resulted from cross of two unnamed selections of *S. sorbifolia* in 1998; selected in 2000, hybridized by Joannis Jacobus Petrus, Netherlands.

PROPAGATION: Easy to root from softwood, greenwood or hardwood cuttings, preferably in well drained medium under mist; division is a good method; seeds can be sown as soon as ripe and will germinate.

ADDITIONAL NOTES: About four legitimate species although over the years I have seen many more listed. The Arnold Arboretum had a large collection in the rose garden, many appearing so similar as to be inseparable. All showy in flower initially, but as inflorescences mature, they become brown and the worse for wear.

NATIVE HABITAT: Northern Asia from Ural to Japan. Cultivated 1759.

RELATED SPECIES:

Sorbaria kirilowii (Regel & Tiling) Maxim. (formerly ***Sorbaria arborea*** C.K. Schneid.), (sôr-bā'ri-a kē-ri-lōw'ē-ī), Tree Falsespirea, is a large, spreading shrub to 15' with 13 to 17 slender-pointed leaflets. The white flowers are produced in large 12 to 15" long and wide panicles. Leaflets and stems are pubescent. Central and western China. Introduced 1908 by Wilson. Zone (4)5 to 7. Have seen in Maine.

Sorbaria tomentosa (Lindl.) Rehd., (sôr-bā'ri-a tō-men-tō'sa), Kashmir Falsespirea, is a rather graceful, 6 to 9' (12') high shrub with 11 to 23 sharply toothed and tapered, 2 to 4" long, 1/4 to 5/8" wide, single serrate, glabrous leaflets, in a 9 to 15" long leaf. The young glabrous stems are usually a rich red. The white flowers occur in large, conical, 1 to 1 1/2' long and 8 to 14" wide panicles in (June)July and August. Handsome in full flower with the large billowy white panicles. Flowers age to brown and there always seems to be a transition between white and brown, never continuous white changing to brown. Possibly best to remove the old flower panicles. This is a handsome shrub which could be planted more than it is, especially in large masses along highways or in open spaces. Variety *angustifolia* (Wenz.) Rahn is the plant formerly listed as *S. aitchisonii* (Helms.) Rehd., the leaflet drawing reflecting the *angustifolia* epithet. Afghanistan, Western Pakistan, Kashmir. Introduced 1895. Zone (5)6 to 7.

Single leaflet

Sorbus alnifolia (Sieb. & Zucc.) K. Koch — Korean Mountainash
(sôr'bus al-ni-fō'li-a)

FAMILY: Rosaceae

LEAVES: Alternate, simple, 2 to 4" long, 3/4 to 1 1/2" wide, ovate to elliptic-ovate, short-acuminate, rounded at base, unequally serrate, glabrous above, glabrous or slightly pubescent beneath, on vigorous shoots sometimes pubescent, with 6 to 10 pairs of veins, leaf shape resembles *Fagus* to a degree, lustrous dark green; petiole—1/2 to 3/4" long.

BUDS: Oblong, terminal bud scarcely larger than the lateral, solitary, sessile, with several dark margined scales, the inner of which are more or less pubescent with long hairs often matted in gum.

STEM: Moderate, lustrous reddish brown, prominent small gray lenticels; on older stems lenticels become distinctly diamond-shaped.

SIZE: 40 to 50' in height by 20 to 30'(50') in spread although can grow to 60'.

HARDINESS: Zone 4 to 7, growing successfully at Minnesota Landscape Arboretum.

HABIT: Pyramidal when young developing a weakly pyramidal-oval to almost rounded outline at maturity; have also seen broad rounded trees.

RATE: Medium to fast, 10 to 12' over a 5 to 7 year period.

TEXTURE: Medium in all seasons.

BARK: Gray on old trunks, almost beech-like; the first time I witnessed Korean Mountainash was at the Arnold Arboretum and was instantly taken by the beautiful foliage, flowers, bark and habit; one of my favorite all around trees; unfortunately, not very well-known.

LEAF COLOR: New leaves a rich bright fresh spring green; lustrous dark green in summer changing to yellow, orange, and golden brown in fall; the leaves are simple and do not look anything like what we normally consider a mountainash leaf; look like beech or hornbeam leaves.

FLOWERS: Perfect, white, 1/2" diameter, borne in 6- to 10-flowered, flat-topped, 2 to 3" diameter corymbs in May, beautiful in flower but shows an alternate sequence, heavy one year, lighter the next.

FRUIT: Roundish or obovoid pome, pinkish red to orangish red to scarlet, bloomy, speckled with dark lenticels, 3/8 to 5/8" long, September–October and persisting, spectacular, at its best perhaps the handsomest of all mountainash for fruit effect.

CULTURE: Transplant balled-and-burlapped into any well-drained soil; very pH adaptable; does not withstand polluted conditions; prune in winter or early spring; Donald Wyman noted that it was one of the most successful of the flowering trees introduced by the Arnold Arboretum from Japan and required little cultural attention.

DISEASES AND INSECTS: Discussed under *Sorbus aucuparia*, the least susceptible to borer injury; Hasselkus, Wisconsin, reported fireblight susceptibility; fireblight was reported on the species from trees growing in Washington, DC and Allentown, NJ, also reported on *S. folgeri* in same paper, see *Plant Diseases* 79(4):424 (1995).

LANDSCAPE VALUE: Specimen tree for lawns; not for streets or downtown city areas; the best of the mountainash; difficult to believe it is even related to the genus *Sorbus*, botanically placed in the section *Micromeles*.

CULTIVARS:

'Redbird'—Listed as having rosy red fruits that persist into winter and serve as a food source for birds; narrow upright columnar form; rich golden yellow fall color; possibly same as 'Skyline', 'Skyline', as observed at Hillier, was similar to 'Redbird', 'Skyline' was about 50' high in 1999.

PROPAGATION: Seeds require 3 months or more of cold stratification at 41°F in moist medium.

ADDITIONAL NOTES: Like most mountainash there is always the threat of fireblight and borer damage. Probably best not to utilize the tree in high stress environments (urban settings) where it would be predisposed to insect or disease infestations. I monitored the trees in the Arnold's collection during sabbatical and seldom a day would pass when I did not give them a caring inspection. The fruits can be spectacular and, during a heavy flowering year, it is the equal of any fruiting tree. The Arnold also has an upright form that is somewhat broad-columnar. To my knowledge it does not have a cultivar name although the name 'Skyline' appears in some literature. This selection was made by Alf Alford, Hillier Nursery, in 1962. I considered this a possibility for use in the South (Zone 7) but remembered trees planted at the Biltmore Estate, Asheville, NC and even they died. Mountainash and heat, particularly high night temperatures, are diametrically opposed.

NATIVE HABITAT: Central China to Korea and Japan. Introduced 1892.

Sorbus aucuparia L. — European Mountainash, Rowan, Common Mountainash

(sôr'bus aw-kū-pā'ri-a)

LEAVES: Alternate, pinnately compound, 5 to 9" long, 9 to 15(19) leaflets, 3/4 to 2 1/2" long, oblong to oblong-lanceolate, acute or obtusish, serrate, usually entire in lower third, dull dark green above, glaucescent beneath and pubescent, at least when young, leaflet base asymmetric.

BUDS: Terminal—large, woolly, 1/2" long, lateral often reduced with several scales, the inner of which are more or less pubescent, reddish brown.

STEM: Young branches pubescent, becoming glabrous, grayish brown and shiny when older.

SIZE: 20 to 40'(60') in height with a spread of 2/3's to equal the height; national champion is 46' by 47' in Seattle, WA.

HARDINESS: Zone 3 to 6 or 7; excessive summer heat induces problems; high night temperatures limit growth.

HABIT: Erect and oval in youth forming an ovate or spherical, gracefully open head at maturity; often low-branched or multi-stemmed.

RATE: Medium, 25 to 30' over a 20-year period.

TEXTURE: Medium-fine in leaf, medium or medium-coarse in winter.

BARK: Light grayish brown in color, usually smooth, but often somewhat slightly roughened on old trunks.

LEAF COLOR: Flat, dull dark green in summer; fall color ranges from green to yellow to reddish, often a fine reddish purple.

FLOWERS: White, 1/3" across, malodorous, borne in 3 to 5" diameter, flat-topped corymbs in May; effective, but not outstanding; not as showy as *S. alnifolia*.

FRUIT: Small, berry-like pome, 1/4 to 3/8" diameter, orange-red; late August into September, very handsome, frequented by birds and seldom persisting for any time; made into an alcoholic drink and also processed into juice and vinegar, stewed, made into tea, and used medicinally.

CULTURE: Transplant balled-and-burlapped into well-drained loam; prefers acid soils and is often short-lived on chalky soils; have seen far too many problems on the species especially where stress is common, does not fare well in compacted soils, polluted atmospheres and the like; high summer temperatures appear to limit growth; I have not seen a single European Mountainash in Zone 8 and generally those in Zone 7 are short-lived; stress apparently predisposes the species to canker and borer.

DISEASES AND INSECTS: Fireblight can be devastating, crown gall, canker, leaf rusts, scab, aphids, pear leaf blister mite, Japanese leafhopper, roundheaded borer, mountainash sawfly, and scales; borers are serious in weakened and poorly growing trees; the best line of defense is a vigorous, healthy, actively growing tree.

LANDSCAPE VALUE: Excellent for fruit effect but its use should be tempered by the knowledge that it is susceptible to many pests; use in northern climates.

CULTIVARS: There are numerous cultivars, some of which were branch sports and others which came about through hybridization. For fruit production (edible) utilize two cultivars for cross-pollination. The following represent a small complement of the different types.

'Apricot Queen'—Apricot-colored fruit.

'Aspleniifolia'—Leaflets doubly serrate and supposedly deeply divided; however, the one tree I saw was just a degree more saw-toothed than the species.

'Beissneri'—A graceful variety with pinnately lobed leaflets; leaf petioles and branchlets bright red, stems and trunk a rich copper-brown color.

'Black Hawk'—A strong columnar, narrow-oval form with thick dark green leaves and large, orange fruits; appears to be resistant to sun-scald; 30' by 20'; reported to be the best for the Midwest.

'Brilliant Pink'—Pink fruit.

'Brilliant Yellow'—Golden yellow fruit in 3 to 5" wide infructescences; 30' by 20', oval outline; offered by Lake County Nursery.

Cardinal Royal® ('Michred')—Vigorous grower with symmetrical upright narrow-oval habit; leaves dark green above, silvery beneath, rust-red fall color; brilliant red fruits in August–September; introduced by Michigan State University; 35' by 20'.

'Carpet of Gold'—Sulfur yellow to orange fruit; hybrid with *S. cashmiriana*.

'Charming Pink'—Pink fruit; 30' by 20', oval habit; Lake County Nursery offering.

Coral Fire™—Notable attributes include thick dark green leaves, bright red fall color, coral-red fruits; introduced by Pacific Coast Nursery; considered a *S. hupehensis* Schneid. selection and listed here for ease of presentation.

'Edulis'—Fruit larger (1/3 to 3/8" diameter) than species and used for preserves in Europe.

'Fastigiata'—Upright with strongly ascending branches; dark green leaves; good, large, sealing-wax-red fruits; slow-growing, rather coarsely branched.

Ivan's Beauty™ ('Likurnaya')—Attractive small tree, 12 to 15' high; white, tinged pink flowers, dark purple, edible fruit, about the size of small pie cherries; *Sorbus aucuparia* × *Aronia* spp.

Ivan's Belle™ ('Granatnaya')—Small tree with white flowers and wine-red fruits with a sweet-tart flavor; *Sorbus aucuparia* × *Crataegus* spp.

'Longwood Sunset'—Showy orange fruits and burgundy fall foliage; 20' by 20'; hardy to −30°F; Longwood Gardens introduction; listed as *S. rufoferruginea* C.K. Schneid. (*S. commixta* var. *rufoferruginea* C.K. Schneid.) selection, species itself is very similar to *S. commixta*.

'Pendula'—Weeping in a rather irregular, unkempt manner and fruiting quite heavily, 15 to 20' high at landscape maturity; always remember a grouping on the UMass campus, pretty eye-catching; no longer matriculating.

'Rabina'—Upright growth habit; white flowers; large, bright orange fruit, edible fresh or used for juices; Russian selection.

Red Cascade™ ('Dwarfscrown', PP 4,157)—A small, compact oval tree with small orange-red fruits and yellow-orange fall color, size approximates 18' by 8'; listed as a *S. tianschanica* Rupr. form in Schmidt Nursery 1988–89 catalog, now (2007) considered a selection of *S. americana*.

'Red Copper Glow'—Bright scarlet fruits with coral and copper overtones; 30' by 20'; Lake County Nursery offering.

'Rossica' ('Rossica Major')—Upright oval, 30' by 18'; dark green leaves turn rusty orange in fall; white flowers, red fruits; listed by Schmidt Nursery.

'Scarlet King'—Scarlet fruit.

'Shipova'—Yellow-orange, edible fruit about the size of apricot; pyramidal habit, small to medium size; *S. aucuparia* × *Pyrus* spp.; from Yugoslavia.

'Wilson'—Dense columnar form, red fruit, 30'.

'Xanthocarpa'—Yellow fruits, more properly amber-yellow to orange-yellow.

PROPAGATION: Seeds require 60 to 120 days of cold, moist stratification at 38°F. Cuttings have been rooted with some success. See *Scientia Horticulturae* 42:169–175 (1990). Cultivars are budded or grafted onto seedling understocks.

ADDITIONAL NOTES: My son Matt and I were hiking in the Lake District (Windemere) in England and growing from the rocky mountainsides were *S. aucuparia*. Based on native soil adaptability, the plant should withstand urban soils. Obviously, the cool, moist English climate is essential to long-term performance.

NATIVE HABITAT: Europe to western Asia and Siberia, and naturalized in North America. Long cultivated.

RELATED SPECIES:

Sorbus americana Marsh. — American Mountainash
(sôr'bus a-mer-i-kā'na)

LEAVES: Alternate, compound pinnate, 6 to 12" long, 11 to 17 leaflets, 1 1/2 to 4" long, 1/2 to 3/4" wide, lance-oblong to lanceolate, acuminate, sharply serrate, dark green and glabrous above, paler beneath, pubescent or glabrous, generally serrated almost to the base, where on *S. aucuparia* the serrations start about 1/3 from the base.

Sorbus americana, American Mountainash, is a northern species that grows from 10 to 30' high and is usually a small tree or shrub with a short trunk of spreading, slender branches that form a narrow, open, round-topped crown. National champion is 25' by 38' in Jefferson National Forest, VA. Flowers are white; fruit is a brilliant orange-red to scarlet-red. It frequents borders of cold swamps and bogs, or grows in a stunted form on relatively dry soils; grows slowly and is short-lived. Have observed on the top of the highest mountains, Brasstown and Rabun Balds, in Georgia; attractive in the right situations. Bonnie and I see the species everywhere from Maine to the higher elevations of the southern Appalachians. The fall color can be beautiful, almost orange-yellow to reddish purple. Fruits ripen in September in the Virginia

Blue Ridge Mountains. Quite a beautiful small tree but finicky about heat and drought stress. Need to inject, via breeding, another rosaceous species with great heat tolerance. Several intergeneric hybrids, *×Crataegosorbus*, *×Sorbaronia* C.K. Schneid., *×Sorbocotoneaster* Pojark., and *×Sorbopyrus* C.K. Schneid., are known. At Hillier, *×Sorbaronia alpina* (Willd.) C.K. Schneid. and *×S. dippelii* (Zabel) C.K. Schneid. were observed but neither were outstanding. The latter grew in the Arnold's shrub collection. Dr. Harold Pellett, retired University of Minnesota, has worked with many of these intergenerics without releasing any commercial selections. Ranges from Newfoundland to Manitoba, south to Michigan, and North Carolina along the Appalachian Mountains. Cultivated 1811. Hardy to Zone 2 (−40 to −50°F).

***Sorbus aria* (L.) Crantz.** — Whitebeam Mountainash
(sôr'bus ä'r-ē-a)

LEAVES: Alternate, simple, 2 to 4" (5") long, one-half to two-third's as wide, elliptic to broad-elliptic or ovate, obtuse or acute, cuneate or rounded, double serrate except at base, dull green to lustrous dark green above, covered with whitish tomentum below, 8 to 13 parallel vein pairs; petiole—1/2 to 1" long.

Sorbus aria, Whitebeam Mountainash, is a tree which develops a broad-pyramidal or ovoid head. This species grows 35 to 45' tall and has simple, leathery, gray-green to lustrous dark green leaves (upper surface) while the lower surface is white-tomentose in summer. Fall color varies from pale green to golden brown to reddish. Flowers are white, about 1/3" across, borne in 2 to 3" wide, terminal corymbs in May. Fruit is 1/2" diameter, orange-red or scarlet, ovoid or rounded, berry-like pome that ripens in September through October. The leaves are quite different from what we associate with a "normal" mountainash leaf. There are several cultivars of note: 'Aurea' is a type with yellow foliage; 'Magnifica' with dense conical crown, large dark green leaves with snow white tomentum beneath, yellow fall color with leaves holding late; 'Majestica' with fruits as much as 5/8" in diameter and the leaves reach 7" in length; 'Ottery' is a hybrid between *S. aria* 'Lutescens' and 'Majestica', develops into a well-proportioned tree with uniform branch structure, leaves gray-silver and less prone to browning and abscission. Grows naturally on the chalky soils of the south of England and tolerates maritime as well as urban conditions. Native to Europe. Long cultivated. Zone 5.

'Magnifica'

***Sorbus cashmiriana* Hedl.** — Kashmir Mountainash
(sôr'bus kash-mēr-ē-ā'na)

LEAVES: Alternate, compound pinnate, 3 1/2 to 7" long, 13 to 19 leaflets, 1 to 2" long, 3/8 to 5/8" wide, lanceolate to oblong, acute, sharply serrate to base, rich green above and glabrous, gray-green below.

Sorbus cashmiriana, Kashmir Mountainash, develops a conical crown and grows 20 to 40' high with an equal spread. The flowers are pinkish white, 3/4" diameter, and borne in mid to late May in 3 to 5" wide, lax corymbs. In fall the leaves may change to a good red. The white fruits are about 3/8" diameter and are often tinged pink; the fruit stalks are pink to red in color. This species has been used in hybridizing with *S. aucuparia* by European nurserymen. Some of the cultivars include: 'Carpet of Gold' with yellow fruits; 'Kirsten Pink' with dark pink fruits; and 'Maidenblush' with pale pink fruits. Wyman considered this species well worthy of a trial wherever mountainashes are grown. The exact taxonomic status is questionable; the trees I have seen are more loose and open than *S. aucuparia* types with smaller, fine-textured leaflets and bear large, loose, 5 to 7" wide corymbs that are eventually laden with the handsome white to pinkish fruit. Native to Himalayas. Introduced 1949 into the Arnold Arboretum. Zone 4 to 5.

ADDITIONAL NOTES: *Sorbus* presents a real challenge to the taxonomist and horticulturist. There are numerous hybrids and cultivars and the previously mentioned intergeneric hybrids with *Aronia*, *Cotoneaster*, *Crataegus* and *Pyrus*. The treatment I have presented is minimalist and I recommend the reader consult Bean, Hillier, Krüssmann, and *The New RHS Dictionary of Gardening* for additional information. I have observed so many European Mountainashes decimated by fireblight and borers in the Midwest and East that it became somewhat discouraging to recommend the tree to the gardener. The Arnold Arboretum had a significant collection and I delighted in the magnificent fruit displays that ranged in color from white, pink, yellow, orange to red and the excellent fall color on species like *S. commixta* and *S. esserteauana* Koehne. In Europe, and especially England, they are planted in abundance. The cool, moist climate is more to their liking. In the United States, extreme heat and drought predispose them to many problems.

Unfortunately, since moving South, *Sorbus* has been removed from my gardening vocabulary simply because the plants do not prosper (survive) in Zones 7 to 9. In fruit, there are few trees that equal the mountainash especially some of the white, pink and coral-pink colored forms. In January 1989, I heard Dr. Hugh McAllister present a lecture on *Sorbus* at the Pershore Nursery Conference, Pershore, England. He provided an excellent overview of the garden attributes and discussed the confusion in identification. His book, *The Genus Sorbus: Mountain Ash and Other Rowans*, Kew Publishing (2005), is the best and only current reference. There are 120 or so species and since *Sorbus* reproduces apomictically (without normal fertilization), numerous microspecies are known which further confound taxonomy. In brief, the best advice to gardeners is to enjoy the mountainash for their lovely fruit and fall color.

Other species of some interest but limited landscape availability include: ***Sorbus commixta*** Hedl., (sôr'bus com-miks'ta), Japanese Mountainash, with white flowers in 4 to 6" wide inflorescences and globose, 3/8" wide, lustrous bright red fruits, 20 to 30', Zone 5; ***Sorbus decora*** Sarg. (C.K. Schneid.), (sôr'bus de-ko'ra), Showy Mountainash, with white flowers and red fruit. Bailey Nursery considers it the hardiest of the mountainash grown in the United States, 20 to 25', Zone 2 to 5; and ***Sorbus discolor*** (Maxim.), (sôr'bus dis'kul-êr), Snowberry Mountainash, with white flowers, 2 to 4(6") wide, bright scarlet

fruit clusters, 20 to 30', Zone 2. Have seen red fruits on cultivated *S. discolor*, however, the literature lists fruit as white-yellow, occasionally pink. I have seen these species and was quite impressed by their fruit displays and fall color especially in the case of *S. commixta*. There is little doubt that *Sorbus* taxa are terribly confused. ***Sorbus folgneri*** (C.K. Schneid.) Rehd. (sôr'bus fôlg-ner'ë), is a simple-leaf type, dark green above, gray to white pubescent below, turning rich orange-red in fall. White flowers yield dark red to purple-red, ovoid to obovoid fruit. Don Jacobs grew this successfully in Decatur, GA along with *S. aria*. Don is one of the great plantsmen in the Southeast and has introduced many herbaceous and woody plants under the "Eco" banner. His garden is shaded and protected and is cooler and moister than most. Don has straightened me out more than once about the adaptability of certain species. I did see the mountainashes at his garden. Does that make me a believer in their Southeastern adaptability? No! Zone 5 to 6(7). Central China. Introduced 1901.

Two other *Sorbus* that appear in northern latitudes and are often listed by nurseries include: ***Sorbus ×hybrida*** L. and ***Sorbus ×thuringiaca*** (Nyman) Shonach. Both are medium-sized, pyramidal oval trees about 25 to 35' high and two third's as wide. *Sorbus ×hybrida* (*S. aria* × *S. aucuparia*) is a tetraploid apomictic species and reproduces true-to-type from seed. Has been included with *S. ×thuringiaca* in some literature. The leaves are deeply lobed and essentially simple, but often cut to the midvein, the overall effect somewhat oak-like. Generally, they are lobed toward their end, lobes increasing in depth toward the base. Size ranges from 3 to 3 1/2" long, 2 to 2 1/2" wide, dull dark green above, white pubescent below, with a 1/2 to 1" long petiole. White flowers occur in 2 to 5" wide corymbs and are followed by globose, 1/2 to 5/8" wide, deep red fruits. *Sorbus ×thuringiaca* is often called the Oakleaf Mountainash and is a hybrid between *S. aucuparia* and *S. aria*. The habit is upright with numerous ascending branches forming with time a dense, rhombic crown, eventually 20 to 40' high. White flowers occur in 3 to 5" wide corymbs, followed by 3/8" wide, globose or ellipsoidal, bright red fruits. The leaves are leathery dark green above covered with dull whitish tomentum below. Leaves average 3 to 6" long and have the lobing pattern of *S. ×hybrida*. Leaves are 2 to 2 1/2 times as long as wide. 'Fastigiata' is similar to the species but differs in more fastigiate form perhaps twice as tall as wide at maturity. Both species (hybrids) originated in or are native to Europe. Zone (3)4 to 5.

Spiraea L. — Spirea

FAMILY: Rosaceae

Spiraea, Spirea, although often assessed as the stepchild of flowering shrubs, is possibly more ubiquitous in American (and European) gardens than any shrub group except the Rose, *Rosa*, species and cultivars. Approximately 80 species occur in the north temperate regions. My Midwest upbringing introduced me to *S. ×vanhouttei*, which was ensconced in virtually every landscape. Two Vanhoutte Spireas framed the front porch of our Cincinnati home. My Dad would cut them back; regenerate they did with even greater ferocity. Tenacious to a fault and therefore widely planted from Zone 3 to 9.

How to identify a spirea . . . actually not clear-cut. Alternate leaf arrangement, simple leaves; white, pink, rose, almost red flowers in corymbs or panicles, opening before leaves or into mid-late summer; shrubs 18" to 10' and larger; flower on new or old wood depending on species or cultivar; fruit a follicle with tiny, dust-like seeds; stems often angled, ridged; buds with several imbricate scales.

Attempted to breed for improved sun and heat tolerant foliage (yellow) and flower colors with no success. Seeds germinate like grass seed, often flowering the first year so evaluation is rapid-fire. Controlled cross between *S. virginiana* × *S. japonica* resulted in six, unique, intermediate seedlings. Would prove a fruitful genus for controlled breeding as the possible combinations and permutations are endless.

Remarkably, over 40 yellow- to gold-foliage *Spiraea japonica* are known yet *none* holds the color (i.e. fades to green, bleaches to white, or brown) past June unless kept in an active state of growth; based on my hybrids of *S. virginiana* and *S. japonica*, I believe there is room for wide crosses within the genus. See Dirr, A look at *Spiraea* cultivars shows an embarrassment of riches, *NMPro* 16(4): 21–22, 88–90, 95–96. Also the RHS Plant Trials evaluated *S. japonica*. See Diana Miller, *Spiraea japonica* with coloured leaves, RHS Plant Bulletin #4, November 2003, downloadable at www.rhs.org.uk. The assessments are discussed under *S. ×bumalda* and *S. japonica* in the Manual.

Spiraea ×bumalda Burvénich — Bumald Spirea (result of a cross between *S. albiflora* and *S. japonica*)

(spī-rē'a bū-mal'da)

FAMILY: Rosaceae

LEAVES: Alternate, simple, 1 to 3" long, ovate-lanceolate, apex pointed, base narrowed, teeth mostly double, sharp, pinkish-red-purple when young, finally dark green, almost bluish green.

STEM: Brown, slightly angled in cross section, somewhat lined or ridged, glabrous.

SIZE: 2 to 3' (4 to 5') high and 3 to 5' wide.

HARDINESS: Zone 3 to 8, some tip kill on 'Anthony Waterer' and 'Froebelii' in Maine.

HABIT: A broad, flat-topped, low shrub, densely twiggy with erect branches, often mounded in habit, clean, relatively refined shrub.

RATE: Fast.

TEXTURE: Medium-fine in all seasons.

LEAF COLOR: Pinkish to reddish when unfolding changing to dark bluish green at maturity; leaves tend to show cream to yellow variegation patterns, particularly 'Anthony Waterer'; often turning bronzy red to purplish in fall; seldom spectacular; very early leafing as is true for many spireas, showing leaf color by early March in Athens.

FLOWERS: Perfect, white to deep pink, (May)June into August, borne in 4 to 6" diameter, flat-topped corymbs; flowers on new growth; flowers mid to late May into early June in Athens, often sporadically thereafter.

FRUIT: Dry, brown follicle, not ornamental, maintained on large infructescence through winter, almost better to remove after flowering since fruits are rather ugly, this, in turn, induces new growth and resultant flowers.

CULTURE: Largely container-grown, easy to transplant; tolerant of many soils except those which are extremely wet; prefers full sun and open areas; pruning must be based on type of wood upon which flowers are produced; *S. ×bumalda* and *S. japonica* should be pruned in early spring before growth starts if pruning is required, after flowers fade, remove them, and a second flush of growth is stimulated that will also produce additional flowers.

DISEASES AND INSECTS: Subject to many of the problems that afflict other members of the Rosaceae; fireblight, bacterial hairy root, leaf spot, powdery mildews, root rot, spirea aphid, oblique-banded leaf roller, scales, caterpillars and root-knot nematode; based on my experience it is difficult to kill a spirea.

LANDSCAPE VALUE: Good filler or facer plant, can be used as a low massing plant, possibly as a bank cover for it suckers from the roots; often grouped in 3s and 5s, mixed with needle evergreens for color, especially yellow-leaf types.

CULTIVARS: *Spiraea ×bumalda* is almost an enigma, and most European authorities place its cultivars (such as 'Anthony Waterer' and 'Froebelii') under *S. japonica*. In the hybrid form, *S. ×bumalda* is considered a cross between *S. japonica* and *S. albiflora*. *Spiraea ×bumalda* was described in 1891. England's Kew Gardens received it in 1885 from Karl Froebel of Zurich. (The original *S. ×bumalda* was a dwarf plant, and a high proportion of the leaves were either marked with yellow or were totally yellow.) The emerging leaves of *S. ×bumalda* are brownish red and essentially hairless and mature to a bluish green. The flowers are carmine-pink. Many authors have noted the instability of this clone, remarking that all the plants propagated throughout the world from this one plant are not the same due to the numerous branch sports.

In this edition, meshed ALL (most) cultivars with *S. japonica*. No real differences in culture, diseases, garden attributes, etc. I probably made it more difficult than necessary in the past editions.

Spiraea japonica L. f. — Japanese Spirea

(spī-rē'a ja-pon'i-ka)

LEAVES: Alternate, simple, ovate to ovate-oblong, 1 to 3" long, 1/3 to 1 1/2" wide, acute, lustrous dark green, glaucescent beneath and usually pubescent on the veins; petiole—about 1/8 to 1/5" long.

Spiraea japonica is almost excessively variable and defies any reasonable description. It is most often considered a 4 to 5' high shrub with rounded, flattened or angled, glabrous or hairy branches. The leaves range from 1 to 3" long with distinct, sharp serrations. The plant has escaped and I have seen it in the north

Georgia mountains: at Moccasin State Park along the hiking trail and along roads in Rabun County. Normal flower color is rosy pink to carmine, rarely white, with inflorescences in some of the garden forms measuring as large as 12" in diameter. Ohwi, in his *Flora of Japan*, noted that the species is common and variable where it is found in the mountains of Hokkaido, Honshu, Shikoku, and Kyushu. It is also found in Korea, and in China north to the Himalayas. This wide geographic range no doubt offers wonderful opportunities for the selection of different forms. Zone 4 to 8.

CULTIVARS: Too many . . . and still multiplying. Need a good yellow that holds color in heat, drought, stress but have yet to see one; have grown hundreds of seedlings from the various yellow-leaf types without discovering a GREAT one; even in cooler climates like Minnesota, the leaf color fades; also the old dry brown fruits are ugly and ideally later flushes of foliage should cover this detritus.

'Abigail'—Yellow foliage turning green with heat of late spring–summer; pink flowers in mid-May; 2' by 3', relatively compact habit; only observed in Raulston Arboretum.

'Albiflora'—Could be equated with a white-flowered 'Anthony Waterer'; habit is low (2 to 3'), rounded, dense; the white corymbs which appear in late June and July (late May–early June, Athens) are effectively foiled against the handsome foliage; observed leaves about half-size on February 27, 1991 in Athens; makes an excellent facer plant, mass, or filler in the shrub border; flowers on new wood so can be rejuvenated in early spring; roots very readily from cuttings and is infinitely superior to the large, cumbersome, unkempt, straggly spireas; have seen tremendous chlorosis in some areas of the Midwest; requires acid soil for best growth; has performed well in Zone 7 and the overall foliage color is brighter green than *S. xbumalda* types; 'Leucantha' has larger leaves and inflorescences; cultivated in Japan, introduced before 1868; Zone 4 to 8.

var. *alpina* ('Alpina', 'Nana') Maxim.—A rather handsome variety that has hybridized with *S. xbumalda* cultivars to produce several interesting selections; see *HortScience* 3(3):455 (1988) for specifics, all are described herein; in the common form, the shrub makes a dainty, fine-textured, low-growing mass with pink flowers in late May (in Athens), June or July; it leafs out and flowers later than the *S. xbumalda* types, usually 5 to 10 days later; the small, 5-veined, light blue-green leaves cover the plant thickly and provide a fine foil for the pink flowers; the leaves measure a half-inch or less but range to 1" in some types; the plant ranges from 15 to 30" high to as much as 6' in diameter; over the years, I have allowed it to cascade over walls and used it as a low facer and as a ground cover; the origin of the plant is not clear, it was described in 1879 from a plant found wild on Mt. Hakone in the central island of Japan, it had procumbent or erect stems and grew a "hand-breadth" high, the general consensus is that the form of *S. j.* var. *alpina* in cultivation is of garden origin; the form in cultivation does not come true from seed, with seedlings being more lax and possessing larger leaves; Bean has treated var. *alpina* as a cultivar and listed it as 'Nana' ('Alpina'); the RHS Plant Finder 2007–2008 lists 'Nana' as correct; one objection to *S. j.* var. *alpina* is posed by its retention of old seed heads, which give the plant a rather shabby appearance, in late summer, the plant can look pretty ragged; a final note on *S. j.* var. *alpina* concerns the iron chlorosis that the plants often develop; in the Midwest, I have observed some wonderfully golden forms, and they were not meant to be that way; I have not noticed problems in the South and East on *S. japonica* or on 'Little Princess'; of course, soil pH in the Athens area is 4.5 to 6.0.

'Alpine Gold'—Low-growing, less than 20", twice as wide; small leaves, greenish yellow in spring and summer, yellow to brown in fall.

'Anthony Waterer'—Originated from the original *S. xbumalda* described above; this cultivar also produces branch sports; the best form reaches 3 to 4' high and 4 to 5' wide at maturity; 'Anthony Waterer' has 4 to 6" diameter, essentially flat-topped, carmine-pink inflorescences; the new leaves are brownish red changing to bluish green, they may turn wine-red to russet-red in fall, the leaves emerge in Georgia

in early to mid-March; flowers appear in late May and in June; the reddish purple fall color is apparent by early November; the richly polished brown stems add a degree of winter interest; based on many observations, I am convinced there are numerous (yes, numerous) forms floating around in the nursery trade; at the University's Botanical Garden, a so-called 'Anthony Waterer' planting develops puny, 2" diameter inflorescences and the strangest yellow-green leaf patterns imaginable, some shoots are completely yellow, others are yellow and green, and some are even completely green; another form listed as 'Anthony Waterer' does not develop branch sports and has long-lasting deep cerise-red flowers; flower color is another variable trait, with certain plants displaying flowers of a deep carmine-pink; in the heat of the South, the plants' pigmentation is not as vibrant as that of plants farther north.

In mid-July, 2008 at Bailey Nurseries evaluation garden, 'Anthony Waterer', 'Dart's Red' and 'Neon Flash' with equally vibrant, crimson-red flowers, grew side by side; if I rearranged the labels, no one could distinguish; could probably roll 'Atrosanguinea', 'Coccinea', and 'Crimson Glory' into this mix and be further befuddled; such is the spirea cultivar glut.

'Atrosanguinea'—Beautiful, deep rose-red form with 4 to 5" diameter inflorescences; I grew this plant in Illinois and found the flower color slightly deeper than the "best" 'Anthony Waterer'; the growth habit is more stiff and upright than that of 'Anthony Waterer'; Pellett also mentioned this spirea as one of the best for deep rose-red flower color; will grow 3 to 4' high and wide, 8 to 10' high at Hillier, 1999.

'Blenheim'—Large bushy habit, 32" by 48"; large leaves, some over 2 3/4" long, green variegated cream and pink in spring, losing variegation in summer, bronze in fall, leaf with jagged margin.

'Bullata'—Rather intriguing, low (12 to 15"), ground cover type plant; foliage thickish and bullate, dark almost bluish green above, grayish green beneath, leaves average 1/2 to 1 1/4" long, up to 3/4" wide and are coarsely toothed; flowers deep rosy pink, borne in small, dense corymbs which form a terminal, 1 1/2 to 3" diameter corymb, June–July; valuable as a dwarf shrub, especially in a rock garden setting; often aphid infested and less than desirable in hot climates, best in colder areas; native to Japan, cultivated 1880, Zone 4 to 7.

'Candlelight'—Softer butter yellow foliage, not quite as loud as the other yellow leaf types; light pink flowers; compact-mounded, flat-topped habit, 2 to 3' high; excellent plant in English gardens; certainly not as tall as 'Goldflame'; good orange-red fall color; no mildew or leaf spot at Hillier compared to 'Firelight' and 'Goldflame' which were heavily infested as of July 1999; introduced into cultivation in 1993 by Peter Catt, Liss Forest Nursery, England; received the highest rating in RHS trial.

'Coccinea'—A bud mutation of 'Anthony Waterer' that has deep carmine-red flowers, decidedly more colorful than 'Anthony Waterer'; I first saw it at Bressingham Gardens in England and, although some literature says it differs very little in color, the plant I witnessed was much deeper red; maybe smaller than 'Anthony Waterer', perhaps 2 to 3' high; has developed branch sports; a plant in the University's Botanical Garden collection possessed the deep carmine red flowers; not exactly sure how different it is from S. j. 'Atrosanguinea'; described as being similar to 'Froebelii' by W.J. Bean in *Trees and Shrubs Hardy in the British Isles*; certainly not the same as 'Froebelii' in modern commerce.

'Crimson Glory'—In the Dirr garden, this appears to be nothing more than a deep crimson-red-flowered form of 'Anthony Waterer'; has been stable with no shoot reversions; 3' by 3' in 3 years; planted by street and certainly glows in the May–June period.

'Crispa'—My first introduction to the plant occurred at the Morton Arboretum in Lisle, IL; in most respects, 'Crispa' is similar to 'Anthony Waterer', however, its leaves are slightly twisted and deeply incised, giving the plant a slightly finer-textured appearance than 'Anthony Waterer'; I grew 'Crispa' in my Illinois garden and gave a plant to my sister in Cincinnati but never brought it into my Georgia garden; the plant in Cincinnati was 3 1/2' high and 4 to 5' wide; it showed the yellow-green variegation pattern typical of most 'Anthony Waterer' clones; I suspect 'Crispa' originated as a branch sport of S. *xbumalda* or 'Anthony Waterer' but cannot locate corroborating evidence in the literature; at Wakehurst Place, England, I observed a plant labeled S. *japonica* 'Walluff' that looked exactly like 'Crispa'; this plant is listed in the literature as S. *xbumalda* 'Wallufii' and 'Walluf'; 'Walluf' is described as having a compact growth habit, young leaves reddish without variegation, flowers bright pink-red but lighter than 'Anthony Waterer'; there is no mention of the finely cut leaves on 'Walluf' and I suspect the plant at Wakehurst was labeled incorrectly; also witnessed 'Hessei' with similar characteristics as 'Crispa' at Longstock April 16, 1999; 'Crispa' develops chlorosis in high pH soils, contracts mildew more so than others.

'Dakota Goldcharm®' ('Mertyann')—Another yellow leaf, mounded spirea, bronze new shoots, pink flowers; have tested the plant in Georgia and it does not hold foliage color as well as 'Gold Mound'; supposedly compact form, 12 to 15" by 2 to 3', but has grown rapidly and large; introduced via North Dakota State University, grown from open-pollinated seed of 'Little Princess'; plant about 2 1/2' high at Raulston.

- 'Dart's Red'—A branch sport of 'Anthony Waterer' with deep carmine-red flowers paling somewhat as they mature; 2 to 3' by 4 to 5'; does not produce the albino shoots; introduced by Darthuizer Nursery, Holland.
- 'Dolchica'—Was sent to me by Michael Epp who had read an article that I published on the summer-flowering spireas (see *Amer. Nurseryman* 163(2):53–61 (1986)); the plant, in most respects, has the same fine cutleaf character of 'Crispa' with deep purple-red (bronzy-purple) new growth and fine pink flowers; appears to be more stable, i.e., no variegated shoots and will mature between 1 1/2 and 2 1/2' high, 2 to 4' wide; the plant performed admirably, but contracted aphids more so than other cultivars.
- Double Play™ Artist ('Galen', PPAF)—Rich purple-red foliage in spring, eventually blue-green; flowers described as rich pure pink; compact habit, 2 to 2 1/2' high, slightly wider; Proven Winners® introduction.
- Double Play™ Gold ('Yan', PPAF)—Vibrant, pure golden foliage; pure pink flowers; compact, low mounded habit, 16 to 24" high; Proven Winners®.
- 'Fastigiata'—Stiff, erect branches; white flowers in large, flattened corymbs.
- 'Firelight'—An improved 'Goldflame', with deeper orange new growth and fiery red fall color, does not turn completely green like 'Goldflame'; pink flowers; compact, 1 1/2' by 1 1/2' in 5 years, although have seen 2 to 3' high by 3 to 4' wide for mature plant; like 'Candlelight', a Liss Forest Nursery introduction; my observations indicate it will grow larger than 'Candlelight'; more stable than 'Goldflame' but I have seen a few reversions; also, leaf spot-type diseases and mildew are evident on occasion while 'Candlelight' is clean.
- 'Flaming Globe' (*S. japonica* 'Nana' and *S. ×bumalda*)—Selected because of its rich, coppery pink young foliage, which turns bright yellow in summer and bright red in autumn; fast-growing, dense shrub that forms a 12" globe in 3 years; flowers are rarely produced; from W.H. Perron and Co., a Canadian introduction; see *HortScience* 3(3):455 (1988).
- 'Flaming Mound' (*S. ×bumalda* 'Goldflame' with *S. japonica* 'Nana')—Selected because of flaming red foliage, red flower buds turning yellow, and small, dark pink flowers; has 3" by 3/4" leaves and forms a 24" high and 24" diameter mound; W.H. Perron and Co. introduction.
- 'Flowering Choice' (PP 13,916)—Small, compact, mounded-rounded habit 15 to 18" by 12 to 15"; new leaves purple-red, mid green in summer, purple-red in fall; flowers purple-pink initially fading to lighter pink, opening for up to 15 weeks.
- 'Flowering Mound'—Selected because of young, reddish leaves, which turn yellow, and abundant, dark pink flower clusters during June, July, and August; foliage turns pink-orange after frost; softwood cuttings grow into saleable plants in 17 months; forms a compact, bushy mound 28" high by 36" across in 7 years; W.H. Perron and Co. introduction.
- 'Fortunei'—Was the first representative of *S. japonica* in Western gardens; it was sent from China to England by Robert Fortune in 1849; it was the commonest form in cultivation but has largely lost favor; I have not observed it in American gardens; the deep pink flowers occur in large inflorescences; one of the largest garden forms, often growing to about 5'; may be listed as var. *fortunei* Rehd.
- 'Froebelii'—Has the same characteristics as 'Anthony Waterer', but its habit is slightly taller, 3 to 3 1/2' high, its leaves are slightly larger, its flowers are brighter (at least in the true form), and its inflorescences are smaller; new growth is brownish red and never develops variegated shoots; my observations of United States plants indicate that there is not a great deal of difference between the two, although the origin of 'Froebelii' is different from that of 'Anthony Waterer'; 'Froebelii' was distributed before 1894 by Froebel; Donald Wyman, author of *Shrubs and Vines for American Gardens*, noted that growth after flowering is vigorous enough to cover the dead flower heads; Dr. Harold Pellett, retired University of Minnesota Landscape Arboretum, believes that 'Froebelii' is probably the hardiest, he also believes that it is the best adapted to heat and drought; Wilson Nurseries Inc., Hampshire, IL, discovered a compact form of 'Froebelii' that is smaller and neater in habit; the selection has been called 'Dwarf Froebel' by this author, but more properly 'Gumball'; grew this form in my Georgia garden, and the plant was 3' high and 4' wide; plants in the Botanic Garden are 3 1/2' high and wide; the plant definitely grows larger than originally advertised; the flowers are light pink, but this could be due to the heat; most 'Froebelii' types in cultivation do not have deep flower color compared to 'Anthony Waterer'.
- 'Genpei' ('Shirobana', 'Shibori')—Interesting selection that offers deep rose, pink and white flowers on the same plant; individual inflorescences often have mixed colors; I first saw the plant at the University of British Columbia Botanical Garden, Vancouver, BC, Canada, in August 1985; grows 2 to 3' (4') high and forms a handsome mound; grew the plant for several years and was most impressed by the recurrent flowering that continues through the summer sporadically even if the old inflorescences are not removed; the leaves are a lustrous deep green and probably the handsomest of any *S. japonica* form; the multi-colored flowers may not hold true depending on origin of propagation wood; the flowers are striking at their best, often pink flowers dominate the color matrix, this has occurred on the five plants in the Dirr garden; in our garden, 'Genpei' is combined with 'Annabelle' hydrangea which flowers

- at the same time in early to mid-June; has been the latest flowering of the *S. japonica* and *S. xbumalda* types in our garden; introduced from Japan in 1970.
- 'Glabrata'—Described as a vigorous form with rosy pink flowers in 12" diameter (or larger) corymbs; the broad-ovate leaves can reach 4 to 5" long and 2 1/2 to 3" wide; plant's origin is unknown.
- 'Glenroy Gold'—More yellow-gold than gold with orange-red new growth; probably will grow 2 to 3 feet high and wide; appears stable; irregular growth habit in youth; mildew and leaf spot were observed; not preferable to 'Goldmound'.
- 'Glenroy Goldbun'—Mounded habit, 24" high, 36 to 48" wide; leaves medium sized, less than 2 3/4" long, golden yellow in spring, bright yellow tinged green in summer, golden yellow in autumn.
- 'Glowing Globe' (*S. xbumalda* 'Goldflame' with *S. japonica* 'Nana')—Selected because of reddish pink foliage which turns salmon in the sun, becomes green-yellow in shade; forms a strong, bushy, globose plant 12" in diameter in 3 years; W.H. Perron and Co. introduction.
- 'Glowing Mound' (*S. xbumalda* with *S. japonica* 'Nana')—Selected because of yellow leaves with a pinkish glow change to a coppery pink after the first frost; flowers sparingly, with small, pink flowers; forms a mound, 30" high by 36" across after 3 years; leaves are 2 1/2" long by 1/2 to 3/4" wide; W.H. Perron and Co. introduction.
- Gold Mine™ ('Gomizam')—Bright gold foliage throughout summer on a low mounded, 2' by 2 to 3' plant; soft pink flowers; I have yet to witness a golden leaf spirea that holds in heat of South; in fact, in July 2008, I witnessed less-than-gold plants in St. Paul, MN area; if true, somewhat just less than a worthy introduction, from Lake County Nursery.
- 'Gold Mound' ('Goldmound')—A hybrid between *S. j.* var. *alpina* and *S. xbumalda* 'Goldflame'; introduced by W.H. Perron Co. Ltd., Laval, Quebec, Canada; 'Gold Mound' is a low-mounded form reminiscent of *S. japonica*, with lavender-pink flowers in May and June and golden leaves throughout the growing season; the journal *Dendroflora* 30 (1993) lists this as a hybrid between *S. japonica* 'Nana' and 'Goldflame', and emphatically points out that the notation 'Gold Mound' is incorrect; the golden leaf color fades in summer to a yellow-green; one report noted that 'Gold Mound' burns badly in the heat of the South; from 1987 to 1998 this plant grew in the *Spiraea* test garden at the University's Botanical Garden and performed magnificently; the bright yellow coloration fades to yellow-green but even in August is still decidedly yellow and not green like 'Goldflame'; develops reasonable orangish red fall color; best of all, no foliage burn has been observed and 1987 and 1988 were two of the driest and hottest years on record in the Southeast; might prove a great color addition to shrub and perennial borders, or any spot in full sun where some brightness is welcome; will mature around 2 1/2 to 3 1/2' by 3 to 4'; even in semi-shade, the yellow leaf color is effective upon leafing and lasts until late May—early June in the Dirr garden; two plants of 'Gold Mound' included in a planting of *Baptisia australis* and *Amsonia tabernaemontana*; *Amsonia* contrasts with the blue-purple flowered perennials; leaf spot at Stapeley Gardens, June 24, 1999.
- 'Gold Rush' ('Goldrush')—Name attached to a plant that looked like 'Goldflame' at Marwood Hill, March 13, 2007; Beaver Creek Nursery describes it as spreading-mounding, 18" by 2 to 3'; yellow foliage; gold-bronze in fall; pink flowers.
- 'Golden Carpet' (*S. xbumalda* 'Goldflame' with *S. japonica* 'Nana') (PP 13,615)—Selected because of creeping habit and golden leaves, which are 3/5" long by 1/3" broad; forms a carpet 3" thick by 8" in diameter in 3 years; in contact with soil, branches root easily; W.H. Perron and Co. introduction.
- 'Golden Dome' ('Gold Dome')—Foliage golden yellow in spring and early summer; habit is compact, dome-shaped; rather handsome form that is more compact than 'Goldflame'; appears similar to 'Nyewoods Gold' in habit and foliage characteristics; flowers are lighter pink than 'Goldflame'; some leaf spot occurs, field notes say "chewed up with leaf spot and mildew June 19, 1999 at Savill Garden".
- 'Golden Elf' (PP 12,025)—Probably the smallest yellow-leaf form, reaching 2 to 4" high and acting like a groundcover rather than a shrub; holds foliage color (some fading in the South); one nurseryman described stem diameter as the thickness of frog hair; certainly a unique growth habit; will need evaluation for a few years to learn if it has a place in the everyday landscape; grows larger than original estimates, about 12" high and greater in spread; kind of lumpy growth habit, certainly not in first order of yellow foliage spireas; light pink flowers.
- 'Golden Globe' (*S. xbumalda* 'Goldflame' with *S. japonica* 'Nana')—Chosen for salmon-pink new growth, which changes to golden yellow; color holds until fall, when it turns pink; in sunny, dry locations it forms a dense, globose shrub 10" high by 10" across; W.H. Perron and Co. introduction.
- 'Golden Imp'—Compact, mounded habit, 1 1/2' by 2'; soft golden yellow foliage, yellow-orange in fall; pink flowers; listed by Beaver Creek Nursery.
- 'Golden Princess' ('Lisp', PP 7,537)—New leaves orange-red to bronze-yellow and then change to yellow; flowers are pink; habit is gently mounded with an ultimate height of 30"; leaves appear to be slightly smaller than those of 'Goldflame'; I have seen the plant many times in England and it offers the same fine qualities as 'Gold Mound'; leaf spot and mildew were observed in England; somewhat similar to

- 'Candlelight' at maturity; some leaf spot on isolated plants; found as a seedling by Peter Welch, cross(?) of 'Goldflame' × 'Little Princess', introduced by Peter Catt, Liss Forest Nursery, in 1985, promoted by Bressingham Gardens, and protected by UK Plant Breeders Rights as well as U.S. patent; highest rated in RHS trials.
- Golden Sunrise™ ('Monhud')—Bright yellow leaves mature to yellow-green in summer, copper-orange fall color; pink summer flowers; 3 to 4' high, slightly wider; Monrovia Nursery introduction.
- Golden Thumbelina™ ('KLMthirteen')—Smaller than 'Gold Mound', 2' by 2 to 3'; golden foliage; pink flowers; Roy Klehm selection.
- 'Goldflame'—One of the most popular forms and appears to be on fire when the leaves emerge in spring; russet-orange to bronze-red leaves change to soft yellow, yellow-green and, finally, green; in Georgia, the summer leaf color is green, in England, it is yellowish; the spring leaf colors are often repeated in fall, making a rather handsome display; leaves hold late, often into December in Athens; will grow 2 to 3'(4') high and slightly wider at maturity; flowers are smaller than those of 'Anthony Waterer' and 'Froebeli' and are a rather sickly pink; in England, I have observed the pink flowers in combination with the yellow-green leaves, and eyes and tummy became jaundiced and nauseous, respectively; the bright spot in the makeup of 'Goldflame' is its high heat tolerance, leaf burn has not occurred on plants I have grown or observed in the Southeast; 'Goldflame' displays a high propensity to produce variegated green-and-gold shoots and leaves; it also produces green shoots, which must be removed; this phenomenon seems to occur more frequently on European than on American plants, at Hillier, five plants in one planting showed 40% reversion shoots; perhaps climate affects the stability of this clone; flowers about a week later than 'Dwarf Froebel' ('Gumball') in our garden; leaf spot and mildew were prominent on plants in England.
- 'Green Carpet'—Low growing, 20" high, more than twice as wide; small green leaves, few flowers, reddish orange fall color.
- 'Green Globe' (*S. xbumalda* and *S. japonica* 'Nana')—Selected because of vigorous, compact habit and small, bright green leaves (1" by 1/2"), which turn to brilliant purple-red in early fall; produces small, light pink flowers from June to September; forms a dense globe 7 to 8" tall by 10" in diameter in 4 years.
- Lavender Lady™ ('KLMO')—Rounded habit, 3' by 3 to 4'; soft lavender flowers; green leaves, purple-bronze in fall; selected by Roy Klehm.
- Lavender Princess™ ('KLMnine')—Compact mounded, 2 to 3' by 3'; lavender flowers; green leaves, red-purple fall color; bred and selected by Roy Klehm.
- 'Lemon Drop' (PP 15,016)—A small-leaf form, golden yellow but somewhat irregular in habit; was starting to cook in Zone 7/8 heat on May 20, 2007 at the Center for Applied Nursery Research; next to it was 'Golden Princess' in great shape.
- 'Lemon Princess'—Another yellow foliage form with pink flowers; compact mounded habit, 1 1/2 to 2' high; have grown this in Athens for several years and do not envision any advantages for it over 'Gold Mound'; probably smaller in habit; could this be the same as 'Candlelight'?; Ted Stephens noted it has brighter yellow foliage than 'Gold Mound'.
- 'Lightened Mound' (*S. japonica* 'Nana')—Selected because of creamy lemon leaves, which turn to lime in summer; does best in partial shade, as it sunburns in hot summers; flowers rarely; forms dense mounds 18" tall by 20" in diameter in 2 years; W.H. Perron and Co. introduction.
- 'Limelight'—Listed in *Dendroflora* 30(1993) as having large, soft-yellow leaves; apparently described in Monrovia catalog pre-1990.
- Limemound® ('Monhub', PP 5,834)—An introduction from Monrovia Nursery Co., Azusa, CA, that arose as a branch sport of 'Goldflame'; in spring, dense, slender branches display lemon-yellow leaves with a russet tinge; the leaf color becomes lime-green when the leaves mature, and autumn foliage is orange-red on reddish stems; branches form a uniform dwarf mounded outline; supposedly, 'Limemound' is one zone more cold-hardy than 'Goldflame', which is hardy to Zone 4; will mature around 2' by 3'; in actuality, difficult to separate from 'Gold Mound' and loses yellow color in Zone 7.
- 'Little Princess'—From Holland is one of several closely related forms; this selection has larger leaves and deeper pink flower color than *S. j.* var. *alpina*; after repeated observations it became evident that 'Little Princess' grew faster, larger, and had larger leaves, to 1" long, than var. *alpina*; ultimate size will approach 30" or greater; dense mounded habit, 2' by 3'; has become a popular commercial form; slight leaf spot in England.
- 'Macrophylla'—Has leaves as large as those of 'Glabrata' that display a distinctly inflated (bullate) condition; leaves supposedly color well in autumn, but the flowers are small; witnessed at Hillier, about 5' high; new growth plum-purple; a selection of 'Fortunei'; flowers later, July 7, 1999, at Hillier.
- Magic Carpet™ ('Walbuna', PP 9,363)—Almost a ground cover variation of 'Goldflame'; orange-red to reddish purple young shoots, yellow-gold at maturity; reddish to pinkish flowers, flowers are red-pink; 10 to 18" high, now 2 1/2' by 3 1/2' in U.S. gardens; have watched this selection emerge as a legitimate

- successor to 'Goldflame'; no shoot reversions have been observed; have grown in Dirr garden and color is significantly reduced in heat of summer; selected English garden centers had entire display tables devoted to this cultivar with large color posters and handsome individual pot labels; third generation seedling of 'Goldflame' raised by David Tristram at Walberton Nursery, England; introduced into cultivation in 1994; has become popular in the U.S.; highest rating in RHS trials.
- 'Neon Flash'—An 'Anthony Waterer' type with rich red flowers, reddish new growth, dark green at maturity, and no branch reversions, 3', introduced by Brookside Gardens, Wheaton, MD into the United States from Japan.
- 'Norman'—Another mystery selection, but both Wyman and Brian Mulligan (formerly of the University of Washington Arboretum) describe it as a small, 10 to 12" high, compact plant with rosy pink flowers and raspberry-purple to red fall color that lasts for a month; Mrs. Wister had a plant in her Swarthmore, PA garden and indeed it fit the description to a "T"; the fall foliage is particularly attractive, leaves are much smaller than the typical *S. xbumalda* and *S. japonica*; most plants labeled and sold as 'Norman' are something else.
- 'Nyewoods'—Considered to be the same as *S. j.* var. *alpina*, and, according to an article in *Dendroflora*, 1977, it is a synonym for *S. j.* var. *alpina*; I have observed 'Nyewoods' at several gardens in Ohio, and the proprietors insisted that 'Nyewoods' was different; the 'Nyewoods' I saw offered blue-green foliage, pink flowers and a compact habit; from a landscape viewpoint, the differences are probably not worth fighting over; the Holden Arboretum, Mentor, OH, Millcreek Valley Park, Youngstown, OH, and Wakehurst Place, England, display the plant as a distinct entity; if anything, 'Nyewoods' approximates 'Little Princess' more so than var. *alpina*.
- 'Nyewoods Gold'—A yellow-leafed seedling of the dwarf *S. j.* var. *alpina*; was impressed by foliage color and compactness; leaf spot was observed; introduced by P.G. Zwijnenburg, Booskoop, Netherlands.
- 'Odensada'—Pink; lousy; witnessed at Bailey Nurseries July 15, 2008; grew in proximity to 'Mannon' which had larger pink flowers.
- 'Ovalifolia'—Is sometimes listed as *S. j.* var. *ovalifolia*, offers white flowers in 3 to 5" diameter corymbs.
- 'Petite Pink'—Similar to 'Little Princess' but more upright with richer pink flowers.
- Pink Taffeta™ ('KLMten')—Mounded, 2 to 3' by 3'; similar to 'Little Princess' but grows slightly larger with better purple-gold fall color; Roy Klehm introduction.
- Purple Gem™ ('KLMeleven')—Compact-mounded form, 2' by 3'; green leaves, rich, deep purple fall color; reddish purple flowers; Roy Klehm introduction.
- 'Queen of Golds'—A compact, golden-leaf form that resulted from the breeding work of Peter Moore in Longstock Park Nursery; I asked him why his was special and he responded with "reflect on the name!"; ultimate size about 2' high, slightly wider; flowers pale pink; foliage color holds well in cool climates.
- Red Princess™ ('Manon')—Excellent cerise-red flowers; dark green leaves; stiff, compact branches; first observed at Bridgemere Garden World, June 25, 2006; tested in Georgia and one of the parents, along with *S. virginiana*, of the unique hybrids.
- Royal Knight™ ('KLMtwenty')—Mounded habit, 3' by 4'; deep purple-pink flowers; green leaves turn burgundy in fall; Roy Klehm selection.
- Royal Prince™ ('KLMtwelve')—Mounded 3' by 4'; burgundy emerging shoots, dark green mature foliage, burgundy-red fall color; pinkish purple flowers; Roy Klehm introduction.
- 'Ruberrima'—Has dark rose-red flowers in downy corymbs; the plant grows to 3' and larger and develops a mounded outline, 5' by 8' at Hillier, July 1, 1999; selection of 'Fortunei'.
- 'Snowball'—Unique because of the ball-shaped, white flowers and lighter yellow foliage; another Peter Catt introduction that is being produced by Briggs Nurseries in Olympia, WA.
- 'Sparkling Carpet' (*S. xbumalda* 'Goldflame' and *S. xbumalda*) (PP 13,665)—Selected because of dense, prostrate habit and reddish pink leaves which turn yellow; the branches are stronger and denser than those of 'Golden Carpet' and the leaves are smaller (3/4" long by 1/3" broad); the plant forms a multi-colored carpet 4" thick by 11" across in 3 years; flowers are rare or nonexistent; W.H. Perron and Co. introduction.
- 'Sunburst'—This apparent rename of 'Magic Carpet' was growing in close proximity to 'Magic Carpet' at Longstock Park Nursery in England; I was unable to detect any differences; Peter Moore, propagator, noted that they are the same plant.
- Sundrop™ ('Bailcarol', PPAF)—Experienced for the first time in 2008 at Bailey Nurseries; hybrid of 'Goldmound' and 'Alpina'; pink flowers; yellow foliage holds well in heat, red-tinged in fall; hardier than most yellow/gold spireas, 12 to 15" by 2 to 3'.
- 'Superba'—Is not well-known but is listed in the literature; the only plant I observed was at the Arnold Arboretum in Jamaica Plain, MA; in general, it resembles 'Anthony Waterer', the only difference being that 'Superba' bears flowers of a lighter pink; technically, it is a hybrid between *S. albiflora* and *S. corymbosa*, although I have seen it listed as a *S. xbumalda* type.

'White Gold' (PP 13,609)—Develops good yellow leaf color and clear-white flowers; English nurseryman Peter Catt used *S. japonica* 'Albiflora' and 'Candlelight', a yellow-foliage form; foliage initiates yellow, then greenish, and yellow again in fall; has photobleached (turned white) in heat of Zone 7 and 8.

'Wyndbrook Gold'—Mounded to 28", 1 1/2 to 2 times as wide; medium sized leaves, gold to bronze in spring, yellow-green in summer, orange-brown in fall.

I have a great interest in the dwarf spireas and have grown 'Anthony Waterer', 'Crispa', 'Dolchica', 'Goldflame', 'Gumball', 'Nyewoods', *S. j.* var. *alpina*, *S. j.* var. *a.* 'Little Princess', *S. j.* 'Atrosanguinea', and others. They offered color (late May, June, July) when other shrubs were in the green summer doldrums. Interestingly, 'Goldflame' became almost normal green in August in Athens while I observed the plant on Cape Cod in August and it was distinctly yellow-green. The summer heat has a great influence on whether yellow shrubs stay yellow, purple-purple and so forth. The compact spireas are excellent for modern landscapes where space is at a premium.

ADDITIONAL NOTES: Confused? It is easy to understand why. Indeed there are too many golden spireas. Several southeastern nurseries are making an effort to collect the cultivars for evaluation. In RHS Plant Finder 2008–2009, I discovered 'Allgold', 'Barkby Gold', 'Magnifica', 'Snow Cap', and 'White Cloud'—without descriptions.

How difficult is it to produce gold-leaf seedlings? Simply sow seed of golden forms or green forms in proximity to the golds. However, I doubt if the industry requires another. We need to properly assess those already extant. I need to heed my words for I have made crosses of *S. formosana* (white), *S. japonica* Red Princess™ ('Manon') (red), *S. chamaedryfolia* var. *ulmifolia* (Scop.) Maxim. (pink-lavender, immense inflorescences) and *S. j.* 'Golden Princess'.

PROPAGATION: Seedlings have germinated in sidewalk cracks and edges from 'Froebeli' in our garden; I raised the seedlings to flowering and had golden forms and every growth habit imaginable; obviously from the staggering number of cultivars, it is apparent that the genetic shakeout from seed yields what you read in these *S. xbumalda* and *S. japonica* treatments; admonition—do not attempt this at home for another yellow cultivar could cause horticultural meltdown. All spireas root readily from softwood cuttings taken in May, June, July, August; IBA treatment usually improves rooting but is not necessary in most cases; I have had great success with all the *S. xbumalda* and *S. japonica* forms. Seed requires no special treatment and will germinate readily when directly sown although, if dried, a one-month cold stratification is beneficial.

Spiraea xbilliardii Hérincq — Billiard Spirea

(spī-rē'a bil-yard'ē-ī)

Spiraea xbilliardii resulted from crosses between *S. douglasii* Hook. and *S. salicifolia* L. It is an upright (6') shrub that shows a propensity to sucker. The chief beauty resides in rose-colored flowers that occur in narrow, dense-pyramidal, 4 to 8" long panicles in June to August. The flowers fade to a rather ugly brown and should be removed. It is susceptible to iron chlorosis and should only be planted in acid soil. Other than the pretty flowers, there is little to recommend it. 'Alba' is white-flowered. 'Macrothyrsa' with bright pink flowers in 6 to 8" long panicles is included here. 'Triumphans' has purplish rose flowers in dense, conical panicles and is considered among the finest of late-flowered spireas. These hybrids and West Coast species do not appear as well-adapted to the heat and humidity of the lower Midwest, East, and Southeast. Have seen in European gardens where they are more content. Originated before 1854. Zone 3 to 6.

Spiraea cantoniensis Lour. 'Flore Pleno' ('Lanceata') — Double Reeves Spirea

(spī-rē'a kan-tō-ni-en'sis)

LEAVES: Alternate, simple, rhombic-oblong to rhombic-lanceolate, 1 to 2 1/2" long, 1/2 to 3/4" wide, cuneate, incised serrate, glabrous, bluish green above, pale bluish green beneath; petiole—1/3" long.

Spiraea cantoniensis 'Flore Pleno' ('Lanceata') is more prominent in the South than the species. The habit is mounded-rounded with graceful, wispy, arching branches. Height ranges from 4 to 6' and the spread is similar. The leaves are bluish green and hold late in the fall without coloring. May be almost evergreen in deep South and part of California. The showy white, 1/2" diameter, many-petaled flowers appear in abundance during early April (Athens) in upright terminal corymbs. The flowers open before those of *S. xvanhouttei* and often overlap those of *Vanhoutte*. Pruning should be accomplished after flowering. The leaves and flowers emerge so early (March) that the tender flower buds may be injured by a hard freeze. This species displays excellent heat tolerance and its only requirements are full sun and well-drained soil, although plants in half-shade are presentable. Have collected cuttings in July, treated them with 3,000 ppm IBA quick dip, peat:perlite, mist and rooting was 100%. Grows extremely fast and would be a good filler

in a shrub border. Should not be used for hedges. The species is one of the parents of the ubiquitous *S. xvanhouttei* and is seldom cultivated. The single-flowered form is also attractive but the flowers do not last as long as the doubles. 'Flore Pleno' grew in the Dirr garden for many years and required *no* maintenance. Have observed bud swell and leaf emergence as early as February 15. First Frost™ ('Hatsushimo') has frosty white-pink new growth, fall color is stunning pink with maroon stripes; flowers are completely lost in the spring variegated foliage; grows 3 to 5' high and wide; introduced by Ted Stephens, Nurseries Caroliniana. China, Japan. Introduced 1824. Zone (4)5 to 9. Cappiello reported regular stem damage (dieback) in Orono, ME.

Spiraea xcinerea Zab. 'Grefsheim'

(spī-rē'a sin-e-rē'a)

Spiraea xcinerea 'Grefsheim' is about as handsome an early-flowering spirea as one could ever hope to find.

The small, white flowers clothe the leafless branches in April presenting the entire shrub as a white cloud. Flowers occur about 10 days ahead of *S. xarguta*. In my opinion, it is superior to *S. xarguta* and possibly *S. thunbergii*. It forms a rather dense shrub with arching stems, 4 to 5' high and wide. Leaves are narrow-elliptic or lanceolate, narrowed at both ends, almost entire, or with a few teeth at the apex; about 1" long, 1/3" wide, soft sea green, appressed silky hairs beneath. Result of a cross between *S. cana* Waldst. & Kit. and *S. hypericifolia* L. The hybrid originated before 1884 and the cultivar is of Norwegian origin. Zone 4 to 7(8).

Spiraea nipponica Maxim. 'Snowmound' — Snowmound Nippon Spirea

(spī-rē'a nip-pon'i-ka)

LEAVES: Alternate, simple, narrowly oblong-obovate, 1 to 1 1/2" long, 3/8 to 1/2" wide, toothed at the rounded apex, rarely entire, cuneate, dark blue-green; petiole—1/6 to 1/8" long.

Spiraea nipponica 'Snowmound' has performed admirably and appears to be a superior replacement for *S. xvanhouttei*. The plant grows 3 to 5'(7') high and as wide, with small, dark blue-green leaves and white flowers in small corymbs appearing in late May into June. It maintains a neater, denser outline than Vanhoutte. There have been reports of isolated branches dying out but I have not observed this. Have had reasonably good success with 'Snowmound' on the Georgia campus. 'Halward's Silver' is more compact than the species and densely branched, will grow 30 to 36" in 3 to 5 years, covered with abundant white flowers, introduced by Royal Botanic Garden, Hamilton, Ontario. 'June Bride' is listed but I have yet to witness. 'Rotundifolia' is considered the typical state of the species with broadly obovate or oval, sometimes nearly round, 1/2 to 1" long, sometimes entire, but usually with a few broad teeth at the rounded apex. Variety *tosaensis* hort. not (Yatabe) Mak. is the same as 'Snowmound'. The species is native to the island of Shikoku, Japan. Introduced about 1885. Zone (3)4 to 7(8).

Spiraea prunifolia Sieb. & Zucc. — Bridalwreath Spirea

(spī-rē'a prū-ni-fō'li-a)

LEAVES: Alternate, simple, elliptic to elliptic-oblong, 1 to 2" long, 1/2 to 3/4" wide, acute at ends, finely toothed, almost hacksaw-like, lustrous dark green and glabrous above, finely pubescent beneath; petiole—about 1/8" long, with appressed pubescence.

STEM: Zig-zag, slender, shiny brown, glabrous.

Spiraea prunifolia is an old favorite (I do not know why) growing 4 to 8' tall and 6 to 8' wide. It is an open, coarse, straggly shrub, often leggy, upright and limitedly spreading

with foliage on the upper 50% of the plant. The foliage is shiny dark green in summer and may turn yellow-orange to purplish bronze in fall but is never overwhelming. The flowers are white, double, 1/3" diameter, 3 to 6 together and virtually cover the leafless stems in mid to late April; in Athens it starts to show color in February and is usually in full flower by early March, often into late March. I really see no use for this plant in modern gardens; it belongs to the "Over the hill gang." Remarkably resilient as plants grow along roadsides, aging homes and open fields. How did they get there? I have not observed fruits, so no seeds. The single-flowered form is listed as var. or forma *simpliciflora* Nak. ('Simpliciflora') and is rarely cultivated. 'Plena' is the form described here; introduced from Japan about 1845. Korea, China, Taiwan. Cultivated 1864. Zone 4 to 8.

Spiraea thunbergii Siebold ex Blume — Thunberg Spirea

(spī-rē'a thun-bēr'jē-tī)

LEAVES: Alternate, simple, linear-lanceolate, 1 to 1 1/2" long, 1/8 to 1/4" wide, acuminate to acute, narrow cuneate, finely serrate from apex to almost the base, glabrous, pale to yellow-green; petiole—extremely short.

STEM: Extremely slender and fine, slightly angled, zig-zag, light brown, downy to glabrous, primarily the latter on cultivated plants.

Spiraea thunbergii grows 3 to 5' tall and 3 to 5' wide, often wider than high at maturity. It is a bushy, slender-branched, tiny-leaved shrub, rather loosely spreading and arching and very twiggy.

Foliage is yellowish green in summer and turns yellowish, tinged with orange and bronze in fall and holds late (not very effective). Flowers are white, 1/3" across, March–April (early to mid-March, Athens) before the leaves; about the first spirea to flower; borne in 3- to 5-flowered, sessile umbels. Definitely requires pruning to keep the plant in good condition as it becomes straggly and open. My fondness for the species has increased since coming to Georgia. The wispy, fine-textured foliage of light green contrasts with the darker greens of most shrubs. Have seen mass plantings and was impressed by the effect. 'Fujino Pink' has soft pink flowers and 'Ogon' (Mellow Yellow®) offers soft yellow leaves that fade to yellow-green. A 'Fujino Pink' in our evaluation plots flowered pink; a branch I collected from a plant labeled as such in Ohio and forced in the greenhouse flowered white; perhaps the latter was incorrectly labeled or the greenhouse heat eliminated the pink. Pink color is not long persistent in Zone 7 and flowers, although kissed pink-red in bud, open primarily white. Have also grown 'Mt. Fuji', with variegated pink- to white-marked leaves; not stable and plants revert largely to green. 'Yat Sabusa' has double, white flowers. Native to Japan, China. Introduced 1830. Zone 4 to 8.

Another species, *Spiraea xarguta* Zab., Garland Spirea, is similar to the above but larger growing and, in fact, is a cross between *S. xmultiflora* Zab. × *S. thunbergii*. I cannot see a great deal of difference in the two. The leaves of *S. thunbergii* appear to be serrated throughout their length while in *S. xarguta* the serrations are lacking or occur only above the middle. The oblanceolate leaves are 3/4 to 1 1/2" long, 1/4 to 1/2" wide, light green and glabrous above. *Spiraea xarguta* flowers later than *S. thunbergii*. It was raised sometime before 1884. *S. xarguta* is also designated 'Arguta'. 'Compacta' grows to 4' tall and 'Graciosa' produces early white flowers. All flower on old wood and pruning should be accomplished after flowering. This is also true for *S. prunifolia* and *S. xvanhouttei*.

Spiraea xarguta

Spiraea trilobata L. — Threelobe Spirea

(spī-rē'a trī-lō-bā'ta)

LEAVES: Alternate, simple, roundish, 1/2 to 1" long (1 to 1 1/2" rarely), about as wide, coarsely toothed, sometimes obscurely 3- or 5-lobed, base rounded or sometimes slightly heart-shaped, glaucous green.

STEM: Zig-zag, round.

Spiraea trilobata is a relatively small (4 to 5') shrub of dense compact habit with slender, spreading branches. The small, usually rounded to 3-lobed leaves are bluish green. The pure white flowers occur in 3/4 to 1 1/2" diameter umbels at the ends of leafy shoots and appear in great profusion during May. Was magnificent in flower as I viewed it in the Arnold Arboretum in 1991. In many respects the flowers remind of *S. xvanhouttei*. One of the parents of Vanhoutte. Apparently withstands considerable shade and still flowers well. 'Fairy Queen' is a compact 3' high and wide shrub with dark green, lobed leaves and frothy masses of white flowers in May–June. 'Swan Lake' is considered more floriferous than the species and a degree more compact. Based on photographs I've seen, it might be an excellent alternative to Vanhoutte and the larger growing spireas; it will probably mature between 3 and 4'. Northern China to Siberia and Turkestan. Introduced 1801. Zone 3 to 7.

Spiraea xvanhouttei (Briot) Zab. — Vanhoutte Spirea

(spī-rē'a van-hoot'ē-i)

LEAVES: Alternate, simple, 3/4 to 1 3/4" long, 1/2 to 1 1/4" wide, rhombic-ovate or somewhat obovate, apex pointed, base tapering, teeth irregular, coarse, often incised, obscurely to 3- to 5-lobed, dark blue-green above, glaucous below, glabrous.

STEM: Slender, brown, glabrous.

Spiraea xvanhouttei grows 6 to 8'(10') high and spreads 10 to 12'. The habit is fountain-like or vase-shaped, round-topped with arching branches recurving to the ground, making a tall broad mound. Foliage is a dull bluish green in summer and fall color is nonexistent or perhaps with an overcast of purple. Flowers are white, 1/3" across; April–May (early to mid-April, Athens); borne in many-flowered, 1 to 2" diameter umbels. Very showy in flower. I was spraying weed killer and had a bit left over and decided to apply the rest to the Vanhoutte Spireas which were left by the previous owner. To my surprise, the herbicide did not affect the plant in the slightest. I think this says something about its toughness. This was the most popular of the spireas and is a hybrid between *S. trilobata* × *S. cantoniensis*. The arching, fountain-like habit coupled with the profusion of white flowers has contributed to its popularity with the masses. Firegold™ ('Levgold', PP 19,308) has yellow leaves, some fading with age, discovered as a branch sport in 1997 in Les Cedres, Quebec, Canada by Denis Levac; Bailey Nurseries introduction. 'Gold Fountain' ('Golden Fountain') has yellow-gold leaves; witnessed at FarWest Show in Portland, OR in August 2006, plant looked the worse for wear; possibly too much time in a convention hall; plant at Hillier Garden Center, May 29, 2006, developed green reversion shoots. 'Pink Ice' has pink- and white-mottled young leaves that mature to green; have seen in Europe and now, 2007, in the U.S.; somewhat unstable and can revert to green; slower growing than species, probably 3 to 5' high at maturity. 'Renaissance' is an improved *S. xvanhouttei* with greater foliar disease resistance, otherwise similar to Vanhoutte. 'Snow White', a hybrid from Canada, listed as *S. trilobata* × *S. trichocarpa*, has larger, bright green foliage with no disease problems, larger flowers, and cleaner spent inflorescences, 4 to 5' high, compact-growing. In Zone 7, the foliage of *S. xvanhouttei* appears bedraggled by August–September. There are many better species and certainly for foliage quality and similar floral and habit characteristics, *S. cantoniensis* is superior. Leaf spot caused by *Pleosporella filipendulae* can be serious and result in early defoliation. Appropriate fungicides will control the disease. Zone 3 to 8(9). Raised by Billiard in about 1862.

OTHER SPIRAEA SPECIES

Spiraea alba DuRoi var. *latifolia* (Aiton) Dippel — Broad-leaved Meadowsweet
(spī-rē'a al'ba lat-i-fō'li-a)

Spiraea tomentosa L. — Hardhack, Steeplebush
(spī-rē'a tō-men-tō'sa)

Spiraea alba var. *latifolia* and *S. tomentosa* are common, suckering, 2 to 4' high shrubs along roadsides and in fields. I see them in lingering, flickering flower in Maine during August and September, colors ranging from pink to white. In the former, the leaves are 1 to 3" long, broadly elliptic or obovate-oblong, blue-green and *glabrous* beneath. White to pink flowers occur in pyramidal, glabrous panicles on new growth of the season. Newfoundland and Canada to North Carolina. Cultivated 1789. Zone 3 to 5. The

Spiraea tomentosa

latter species with similar size leaves but yellowish or grayish *pubescence* below and on the angled stems; flowers deep rose to rose-purple in narrow, dense, brownish tomentose, 3 to 8" long panicles. Flowers open from top to bottom. Grows in or near and requires moist soils. Nova Scotia to Georgia, west to Manitoba and Kansas. Introduced 1736. Zone 4 to 6. Neither will win *Spiraea* beauty contests but are reasonably attractive in a late summer sort of way.

***Spiraea betulifolia* Pall. var. *aemiliana* (C. K. Schneid.) Koidz. — Birchleaf Spirea**
(spī-rē'a bet-ū-li-fō'li-a a-mil'ē-ā'na)

Spiraea betulifolia var. *aemiliana* is a compact mounded, rather dense shrub probably 2 to 2 1/2' high at maturity. Leaves 3/4 to 1 1/2" long, broad ovate to rounded, strongly toothed (incised). The white flowers occur in flattish corymbs after the leaves have matured. The principal ornamental characteristic is the long-persistent gold, yellow and bronze fall color. 'Tor' has rich green leaves, yellow-gold, bronze and red fall color; white flowers in compact, dome-shaped clusters, 1 to 1 1/2" across, opening in early May Zone 7; 2 to 3' high. True var. *aemiliana* is generally smaller (8 to 12" high) than the species, however, the plant I have seen in cultivation listed as the variety favors the above description. Japan, Kurile Islands, Kamchatka. Introduced 1812, again in 1892. Zone 4 to 6. A postscript relative to performance reads like an epitaph. Not satisfied with Zone 7 conditions. Probably best in the North.

***Spiraea decumbens* Koch.**
(spī-rē'a dē-kum'benz)

Spiraea decumbens literally jumped into my life during a June visit to Germany. The habit is compact-spreading, probably to 18" high with prostrate branches. It was covered with frothy masses of white flowers. Might be an ideal ground cover species for full sun and certainly could be used in rock gardens. The flowers are only 1/4" diameter but occur in 2" wide, flat-topped corymbs. The mint green leaves are obovate or oval, tapered at both ends, and rather coarsely toothed toward the apex, glabrous with a 1/8" long petiole. Found on limestone soil in the wild. Tested a plant in our Georgia garden but it was not vigorous and died. I suspect the heavy soils and high humidity were lethal. Southeastern Europe in the Alps. Cultivated 1830. Zone 5 to 7.

***Spiraea fritschiana* C. K. Schneid. — Korean Spirea**
(spī-rē'a frit-shē-ā'na)

Spiraea fritschiana is uncommon in the United States but offers dark green foliage and 1 to 3" diameter, flat-topped, white flowers in May–June on a 2 to 3' high, 4 to 5' wide, compact mounded shrub. I have grown this in Illinois and Georgia with success and know that it grows in Fargo, ND which attests to hardiness. Worth a try in difficult climates. Leaves are elliptic or elliptic-ovate to elliptic-oblong, 1 to 3 1/2" long, acute to acuminate, cuneate, simple serrate, with a 1/4" long petiole. Fall color is often a good yellow. This species is closely related to *S. betulifolia*. Pink Parasols® ('Wilma', PP 15,397) grows 2 to 3' high; produces large, pink inflorescences in May–June; blue-green leaves turn yellow-orange-red in fall. Every *S. fritschiana* I observed was white; could this be a hybrid? Listed Zone 4. Central China to Korea. Introduced 1919. Zone (3)4 to 7.

***Spiraea virginiana* Brit.**
(spī-rē'a vēr-jin-i-ā'na)

Spiraea virginiana is a late arrival to the Manual and only because of a lecture given by Professor George Sanko where he showed the plant growing in standing water in Cloudland Canyon, Northwest Georgia. Fast forward to North Carolina Botanical Garden where a sturdy 7 to 8' by 8 to 10' plant blissfully thrives in "normal" soil. Signage says the species is unable to produce viable seed. Ken Moore, former Assistant Director, provided cuttings which root like *Coleus*. A plant in the Georgia trials grew with weed-like vigor . . . beautiful blue-green, oblong to oblanceolate, 1 to 2 1/2" long leaves, entire or toothed at apex, glabrous or finely pubescent on the veins. Leaves die off green, perhaps a hint of yellow. Flowers, white, in 3 to 6" diameter corymbs (as I viewed them), literature stated 1 to 2" diameter, in late May–early June (Zone 7) at the ends of the shoots. Foliage is beautiful, pest-free, heat tolerant. A spirea with wet-soil tolerance and respectable ornamental characteristics might prove garden worthy. Hybrids with *S. japonica*

are described in the introduction. Flowers have been minimal but summer foliage and bronze-orange fall color are notable. *Spiraea virginiana* was the female parent. I suspect the reason for lack of viable seed production in the species is self-sterility *but* when mated with outside pollen, *some* viable seed develops. Found in Virginia, North Carolina, Georgia and Tennessee. Cultivated 1907. Zone 5 to 7.

SPIRAEA SNIPPETS

During sabbatical I collected seeds and cuttings from many spireas, growing and evaluating hundreds of seedlings. Most of the following, though quite impressive in English gardens and nurseries, failed to prosper and excite.

Spiraea chamaedryfolia L. var. ***ulmifolia*** (Scop.) Maxim., with purple young shoots, large leaves, pink flowers on June 4, 1999 at Hillier, Zone 5 to 6.

Spiraea formosana Hayata may be the Taiwanese version of *S. japonica*, large plant, upright, blue-green leaves, pink buds open to white flowers, wild collected material by Chris Chadwell, in flower June 22, 1999 Hannays of Bath; grew large seedling population, all with green leaves and white flowers, except for *one* yellow-foliage variant.

Spiraea hayatana H.L. Li has purple stems, mid-green leaves, purple buds open to pinkish flowers in about 1 1/2" to 2" diameter inflorescences, in flower June 11, 1999 at Longstock, turn miserable brown as they age.

Spiraea media F. Schmidt is a compact shrub with ovate to oblong leaves, toothed at apex or entire, flowers white in racemes? in April–May. A selection, Snow Storm™ ('Darsnorm', PPAF), with large white corymbs is listed as an *S. media* type but looks like *S. japonica* or a hybrid. *Spiraea media* is native to Eastern Europe to Siberia, Japan. Zone 5.

Spiraea micrantha Hook f. was 6' high, 8 to 9' wide with light green foliage and 3 to 6" long, pale pink flowers in lax, leafy corymbs in June. Zone 6.

Spiraea miyabei Koidz. has bronze young leaves 2 1/2" long, pink flowers, June 4, 1999 at Hillier, good-looking at Hillier, took a beating in Athens, white flowers at Raulston May 16, 2004. Zone 6.

Spiraea mollifolia Rehd. has gray leaves, purple stems, cream-white flowers in June. Zone 6.

Stachyurus praecox Sieb. & Zucc.

(sta-che-ū'rus prē'koks)

FAMILY: Stachyuraceae

LEAVES: Alternate, simple, ovate-lanceolate, 3 to 7" long, half as wide, acuminate, rounded, serrate with spreading teeth, lustrous dark green, glabrous or slightly pubescent on veins below.

BUDS: Flower at ends of stems, preformed and visible through winter, when taking cuttings use wood away from terminal since it possesses vegetative buds with the potential to produce new shoots; vegetative buds 1/8" long, several-scaled, reddish brown, sitting directly above raised leaf scar.

STEM: Reddish brown to chestnut-brown, lustrous, glabrous, small oval-rounded, gray lenticels, leaf scars raised, crescent-shaped; pith—white, solid.

Stachyurus praecox is an enigmatic shrub with an element of mystery and beauty that few gardeners know anything about. In an earlier edition, I commented that I had only seen the plant in leaf. Since traveling to the U.S. National Arboretum (early April) and England (March), the off-yellow flowers became almost commonplace. A form at the National had 6 to 8" long flowers. The habit (4 to 6' high) is upright, arching with an overall broad-rounded outline. Gigantic plants, 14' by 20' (Sarah P. Duke), 10' (Wisley), 12' (Stapehill), and 15' by 20' (Savill), are quite common. Should mention that late spring freeze, April 7–8, about 26°F, killed leaves and flowers on the 10' by 14' Georgia test plant. The pale yellow, 1/3" diameter flowers (15 to 24 per inflorescence, counted 20 on inflorescences in the Durr garden) occur in 2 to 3" long (6 to 8" on some cultivated forms), pendulous racemes from each axil in March–April. Mid-March to early April, Sarah P. Duke Gardens, Durham, NC. It is considered one of the finest winter flowering shrubs. Soils should be acid, moist and well-drained. A sunny location is preferred but in the South, light shade is advisable. My observations indicate it is better in a woodland garden. 'Aurea Variegata' is listed by Heronswood as having leaves with green and gold, typical flowers, to 10' high. 'Issai' is a earlier and more precocious flowering form with up to 6" long, yellowish flowers, often each raceme multi-branched with up to 3 divisions. 'Joy Forever' with soft yellow-margined leaves was housed at Longstock, May 28, 2006. I thought this marginal

variegation might mature to cream like 'Magpie', and it was completely cream-margined on May 25, 2006 at Wisley. 'Magpie' is a creamy variegated form that is not particularly stable. I have seen it in Europe under *S. praecox* but understand it correctly belongs with *S. chinensis*. Taxonomic affinity of 'Magpie' is not absolute and the vagaries are discussed in *New Plantsman* 2(1):50–53 (1995). Hillier 2002 places 'Magpie' with *S. praecox*. 'Rubrifolius' has red buds and light pink flowers that lose the color soon after opening. 'Sterling Silver' produces soft silvery or pewter-green leaves with white margins; flowers occur in 4 to 6" long racemes of soft yellow; introduced by Ted Stephens, Nurseries Caroliniana.

Stachyurus chinensis Franch. flowers about 2 weeks later than *S. praecox* with long racemes of yellow flowers. The fruits are rounded, 1/3" diameter, greenish, yellow-red cheeked and berry-like. 'Celina', 'Goldbeater', and 'Joy Forever' (see under *S. praecox*) are listed herein. Japan. Cultivated 1865. Zone 6 to 7(8). Plant dies to ground at Morton Arboretum but regenerates new shoots each summer. Other species have been promoted, particularly through the JC Raulston Arboretum, but are of dubious hardiness. The only one persisting in our garden is *S. praecox*.

OTHER SPECIES:

Stachyurus himalaicus Hook. f. & Thoms. Ex Benth., (sta-che-ū'rus him-a-lā'i-kus), bears 5 to 9" long, oblong-lanceolate leaves with a long, extended, acuminate apex and red petiole; and about 2" long, racemose, inflorescences in April, each flower cup-shaped, wine-purple to rose-pink. Grows 10' high with long yellow-brown stems. Tender. Probably Zone 8 to 10 West Coast. Native to eastern Himalaya, northern Burma (Myanmar), western and central China.

Stachyurus salicifolius Franch., (sta-che-ū'rus sal-is-i-fō'li-us), is an evergreen, willow-leaf species, each lustrous dark green leaf is 6 to 8" long, about 1/2 to 3/4" wide, finely serrated and short petioled. Foliage is beautiful but often injured in Zone 7 winters. A plant in the Dirr garden and one at the Raulston (shade house) are often beaten back. Flowers, pale yellow, in pendent racemes. China, introduced in the 1990s.

Stachyurus szechuanensis, (sta-che-ū'rus sesh-ū-wan-en'sis), is listed by Heronswood Nursery's 2006 catalog; grows to 12' high with 10" long pendent racemes of pale green flowers.

Staphylea trifolia L. — American Bladdernut

(staf-i-lē'a trī-fō'li-a)

FAMILY: Staphyleaceae

LEAVES: Opposite, compound pinnate, 3 leaflets, ovate to broadly ovate, 2 to 4" long, acuminate, sharply and unequally serrate, dark green above, pubescent beneath, sometimes glabrate at maturity, the middle leaflet long-stalked, the laterals shortly so.

BUDS: Solitary, ovoid, glabrous, terminal—usually lacking.

STEM: Moderate, rounded, glabrous, greenish to brown; pith—large, continuous, white.

Fruit

SIZE: 10 to 15' in height, usually taller than wide at maturity.

HARDINESS: Zone 4 to 8.

HABIT: Upright, heavily branched, suckering shrub with smooth striped bark forming a solid aggregate of brush; sometimes wide-spreading; actually a rather attractive shrub; have seen as a small tree.

RATE: Medium to fast.

TEXTURE: Medium in leaf; medium-coarse in winter.

BARK: Light, greenish gray with linear white fissures, branchlets at first pale green with white lenticels, downy, later brownish purple, finally ashen gray, glabrous.

LEAF COLOR: Bright green when emerging eventually turning dark green in summer; developing pale dull yellow in fall.

FLOWERS: Perfect, greenish white, bell-shaped, 1/3" long, borne in nodding, 1 1/2 to 2" long panicles, abundant, April–May.

FRUIT: A 3-lobed, 1 to 1 1/2" long, inflated capsule, pale green changing to light brown, effective in September; usually containing several hard, yellowish brown, 3/16" diameter, rounded seeds.

CULTURE: Prefers moist, well-drained soils; performs better under cultivation than in native haunts; in the wild is often loose and open, but under cultivation takes on a more dense, vigorous nature; have found it in heavy shade just above the flood plain in the University's Botanical Garden.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Not a great deal; could be used in naturalizing; best reserved for parks and other low maintenance areas; rather nice for foliage effect.

PROPAGATION: Seed possesses a double dormancy; do not allow the seed to dry out before stratification; 3 months warm followed by 3 months at 40°F is recommended. Have germinated seeds by sowing in summer with germination the following spring and continuing into the next spring. Softwood and hardwood cuttings root easily. Also can be divided if a few plants are needed. Dug a sucker and included it in the garden. Spread quickly and developed a respectable habit. Noticed after removing the plant that shoots developed from root pieces.

ADDITIONAL NOTES: The most curious aspect of bladdernuts is the inflated, balloon-like fruit.

NATIVE HABITAT: Quebec to Ontario and Minnesota, south to Georgia and Missouri. Cultivated 1640.

RELATED SPECIES:

Staphylea bumalda DC., (staf-i-lē'a bū-mal'da), Bumald Bladdernut, and **Staphylea holocarpa** Hemsl., (staf-i-lē'a hol-ō-kār'pa), are occasionally encountered in gardens. The first is a 6' high, spreading shrub with 3 dark green leaflets and 1/3" wide, dull white flowers in 1 1/2 to 3" wide inflorescences in May–June. Was in full flower in early May at the Arnold Arboretum. Flowered April 26, 1999 at Hillier, flowers smaller than *S. colchica*. Capsule is usually 2-lobed, to 1" long, with yellow-brown seeds. Japan, Korea, China, Manchuria. Introduced 1812. Zone 4 to 6. The second species is a large shrub or small tree to 30' high with 3 leaflets, bronze-purple new growth; pink flowers in slender-stalked, 2 to 4" long panicles; 1 1/2 to 2" long, pear-shaped capsule either acuminate or lobed at the end with 1/4" diameter, lustrous light gray-brown seeds. 'Innocence' is listed in RHS Plant Finder 2008–2009. 'Rosea' has pink flowers and rose capsules. I first experienced 'Rosea' in fruit at Hidcote, in flower at the Arnold Arboretum and Forde Abbey, England. Pink, non-fragrant, 5 petaled, like daffodils, flowers on April 8, 1999 at Hillier. Tree was 30' high. Central China. Also listed as growing in foothills of Japanese Alps. Introduced 1908 by E.H. Wilson. Zone 5 to 6.

Staphylea bumalda
(leaflet)

Staphylea colchica Steven, (staf-i-lē'a kol'chi-ka), Colchis Bladdernut, is somewhat similar to *S. bumalda* but the leaflets are usually in 5's (3's) and the orange-blossom fragrant flowers are borne later, usually in May or June. It, too, is a suckering, upright shrub growing 6 to 10' high. The flowers occur in erect panicles, the largest up to 5" long and wide. Flowers opening April 22, 1999 at Hillier. The 2- to 3-lobed fruits are 2 1/2 to 3" long. The seeds are 1/3" long and pale brown. It is quite handsome in flower. 'Coulombieri' ('Colombieri') may be a hybrid between *S. colchica* and *S. pinnata*. The leaves are composed of 3 to 5 dark green leaflets. Flowers and fruits are intermediate between the parents. 'Hessei' supposedly has red-purple blushed flowers; anything but red-purple as the flowers were white, slightly fragrant, on a 20' by 18' plant, April 9, 1999, Hillier. I saw *S. colchica* in flower at Rockingham Castle, England, in mid-May. It was easily 10' high and 15 to 18' wide and made a fine display. Caucasus. Introduced 1850. Zone 6 to 7.

Staphylea pinnata L., (staf-i-lē'a pin-nā'ta), European Bladdernut, has (3)5 to 7 leaflets; pink buds, white flowers, greenish at base, early April, in 2 to 5" long, narrow, drooping panicles; rounded-subglobose, 1 to 1 1/4" diameter, 2- to 3-lobed capsule with 2/5" diameter, brownish yellow seeds. This is a vigorous, erect-growing shrub. Large, 20' high plant at Hillier that looked like a big, brush pile. Central and southern Europe. Cultivated 1596. Zone 5 to 7.

Stephanandra incisa (Thunb.) Zab. (most disappointing that GRIN lists this as *Neillia incisa* (Thunb.) S.H. Oh) — Cutleaf Stephanandra
(stef-a-nan'dra in-sī'za)

FAMILY: Rosaceae

LEAVES: Alternate, 2-ranked, simple, ovate, 1 to 2" long, or on shoots to 3" long, less in width, long-acuminate, cordate to truncate, incisely lobed and serrate, the lower incisions halfway to the midrib, bright green above, pubescent on the veins beneath; petiole—1/8 to 1/2" long; stipules—linear, toothed, 1/4" long.

BUDS: Small, superposed, ovoid, with about 4 scales.

STEM: Terete, or somewhat 5-lined from the nodes, slender, zig-zag, warm brown, glabrous.

SIZE: 4 to 7' high with an equal or greater spread.

HARDINESS: Zone 4 to 7(8).

HABIT: Graceful shrub with dense, fine to medium-textured foliage and wide-spreading, arching slender branches; tends to form a haystack-like mound; suckers freely from the base.

RATE: Fast.

TEXTURE: Medium to fine in leaf; medium in winter.

STEM COLOR: Warm brown.

LEAF COLOR: Tinged reddish bronze when unfolding, later bright green; red-purple or red-orange in fall, not particularly effective.

FLOWERS: Yellowish white, small, 1/6" diameter; May-June; borne in loose, terminal panicles, 1 to 2 1/2" long; not particularly showy, in fact, I did not know the two small plants in my garden were flowering, although I walked past them every day, until I was doing some hand weeding and inadvertently gazed upon the flowers.

FRUIT: Follicle, not showy.

CULTURE: Easy to transplant, best moved as a container plant; prefers moist, acid, well-drained soil that has been supplemented with peat moss or leaf mold, although tolerant of most soils; full sun or light shade; in exposed, windswept areas the very delicate young branches may be killed, at least near the tips, in winter; simply prune back to live tissue before new growth starts; tends to root wherever the stems touch the soil; will develop chlorosis in high pH soils.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: The species could be used for hedges, massing, screens, or in the shrub border while the low-growing cultivar 'Crispa' makes an excellent facer, bank cover, or ground cover plant.

CULTIVARS:

'Crispa'—Handsome form which grows 1 1/2 to 3' tall and forms a low, thick tangle of stems; it makes an excellent mass or ground cover planting; more common than the species in cultivation.

'Dart's Horizon'—Described as a dense, arching ground cover.

PROPAGATION: Roots readily from cuttings taken at any time of the year. I have used softwood (June and July collected) cuttings and had 100% success; seeds appear to require a warm/cold period or perhaps light scarification followed by about 3 months cold; 3 months warm followed by 3 months cold produced 89% germination.

NATIVE HABITAT: China, Japan, Korea. Grows in thickets on moist slopes, along streams at 1,600 to 3,300' elevation. Cultivated 1872.

RELATED SPECIES:

Stephanandra chinensis Hance, (stef-a-nan'dra chin-en'sis), I experienced on March 2, 2006 at Longstock. Do not know the validity of this species but the shiny red-brown stem coloration was attractive. Leaves are ovate-lanceolate, narrow acuminate, double serrate, bright green. Flowers about 1/2" wide, white, in racemes. China. Zone 7. GRIN lists as *Neillia hanceana* (Kuntze) S.H. Oh.

Stephanandra tanakae (Franch. & Sav.) Franch. & Sav., (stef-a-nan'dra ta-na'kē), Tanaka Stephanandra, is larger (6'), more vigorous-growing than *S. incisa* with larger, 3 to 5" long, 3- to 5-lobed and incisely toothed leaves. It is rather attractive but not preferable to *S. incisa*. Fall color is a warm golden yellow. Successfully growing at Morton and Arnold Arboreta. Japan. Introduced 1893. Zone 5 to 7. GRIN lists as *Neillia tanakae* Franch. & Sav.

Stewartia ovata (Cav.) Weatherby — Mountain Stewartia
(stū-är'ti-a ō-vā'ta)

FAMILY: Theaceae

LEAVES: Alternate, simple, ovate or elliptic to ovate-oblong, 2 to 5" long, about half as wide, acute, usually rounded at the base, serrulate almost to base, dark green above, sparingly pubescent and grayish green beneath, thickish with a rubbery texture; petiole—1/8 to 3/5" long, winged.

BUDS: Solitary or superposed, sessile, compressed-fusiform, with 2 or 3 exposed scales, brown, covered with silky hairs.

STEM: Moderate, subterete, in youth tinged with red above, green or creamy below, distinctly zig-zag; pith—rounded, somewhat spongy.

SIZE: 10 to 15' high and wide.

HARDINESS: Zone 5 to 8.

HABIT: Large shrub or small tree with spreading branches and a bushy habit.

RATE: Slow.

TEXTURE: Medium in leaf and winter.

BARK: Not particularly handsome compared to the exfoliating species; gray-brown, slightly ridged-and-furrowed.

LEAF COLOR: Dark green in summer; beautiful orange to scarlet in fall, although this species is not as colorful as *S. pseudocamellia*; in fact, I have not observed good fall color on *S. ovata*.

FLOWERS: Perfect, white, 5, often 6, concave, obovate petals, each crimped and crenulated, pistils with 5 separate styles, filaments yellow-white, anthers white, orange to purple; each flower 2 1/2 to 3" wide, up to 4" on some plants, July to August; June–July in Athens; full flower on July 2, 1991 at Arnold Arboretum.

FRUIT: Woody, sharply pointed, strongly 5-angled, 1/2 to 1" long, dehiscent capsule, each chamber containing up to 4 winged seeds, dull brown in color.

CULTURE: Applies to *Stewartia* in general, somewhat difficult to transplant and should be moved as a small (4 to 5' or less) container or balled-and-burlapped plant in early spring; the soil should be moist, acid (pH 4.5 to 6.5), abundantly supplemented with leaf mold or peat moss; they do best where there is sun most of the day, but shade during the hottest periods; they seldom require pruning; *S. ovata* is found as an understory shrub along stream banks and occurs in the wild about 20 miles north of Athens, GA; I checked specimens in the Botany Department's herbarium and discovered that plants have been found in rocky, moist soils on the walls of a canyon.

DISEASES AND INSECTS: Basically free of problems.

LANDSCAPE VALUE: *Stewartia*, in general, make specimen plants and should not be hidden in some obscure corner of the landscape; the flowers, fall color and bark are among the best; I have seen plants used in shrub borders or on the edges of woodlands; some shade, at least in hot climates, is probably a necessity; observations in Zone 7 indicate *S. monadelpha*, *S. ovata* and *S. malacodendron* are the best, although the latter is subject to root rot; over the years, several *S. pseudocamellia* have been planted on the campus and in the University's Botanical Garden and none have lived; summer drought and high night temperatures contribute to decline; Coach Dooley has several thriving specimens and seldom fails to point them out when we walk the garden; the beautiful exfoliating cream, tan, rich brown bark of *S. koreana* or *S. pseudocamellia* is unparalleled among *Stewartia* species; beautiful specimens at the Atlanta Botanical Garden.

CULTIVARS:

var. *grandiflora* (Bean) Weatherby—Has larger flowers than the species, up to 4" diameter, and purple stamens; it is beautiful in flower, and may have up to 8 petals; I do not believe everyone is in agreement as to whether this is a true variety for people I have talked with say purple stamens occur in wild populations of the true species; it is best to use var. *grandiflora* as a name to distinguish purple-stamened types, or simply 'Grandiflora'/Grandiflora Group to recognize seed-grown plants with purple stamens and larger flowers.

PROPAGATION: Seeds require a warm/cold treatment and 3 to 5 months warm followed by 3 months cold is probably best; personally I have not had much success with seed although a nurseryman friend, Mr. Don Shadow, Winchester, TN had tremendous success planting seeds in the fall with germination taking place the second spring following planting; the backyard gardener would do well to put the seeds in a clay flower pot, sink it in the ground, and practice the same patience as Mr. Shadow. Cuttings are, to say the least, a challenge; most species can be rooted from softwood cuttings at 70 to 90% using IBA, peat:perlite, mist; it is quite critical that the cuttings are not moved after rooting but allowed to go through a dormancy

period; when new growth is initiated, they should be transplanted; this genus has driven me to the brink of propagation insanity; too many times cuttings have been successfully rooted only to lose them during the overwintering period; I have followed every precaution and have one *S. monadelphæ* that has been successfully overwintered, probably out of 1,000 rooted cuttings. Also seeds can be manipulated by warm/cold treatments to germinate but the resulting seedlings are reluctant to grow; many times I have had bags of seeds with root radicles evident yet have no plants to show; as far as I am concerned nurserymen deserve any price they charge.

Two research papers on tissue culture *J. Environ. Hort.* 15(2):65–68 (1997) and rooting and overwinter survival of stem cuttings *J. Environ. Hort.* 14(3):163–166 (1996) are worthy reading for anyone who has struggled with propagation. Mid-June cuttings treated with either 2,000 or 4,000 ppm IBA rooted in the highest percentages. *Plantsman*, June 2008, offers *Stewartia* in cultivation.

NATIVE HABITAT: North Carolina to Tennessee and Florida. Cultivated 1800. Found in rich soils under other broadleaf trees, sometimes in moist soils, steep slopes, bluffs.

RELATED SPECIES:

***Stewartia koreana* Rehd.**— Korean Stewartia
(stū-är'ti-a kôr-ē-ā'na)

LEAVES: Alternate, simple, elliptic to broad-elliptic, 1 1/4 to 4" long, 3/4 to 3" wide, abruptly acuminate, broad-cuneate or rounded, remotely serrate, dark green and glabrous above, slightly pubescent below.

Stewartia koreana, Korean Stewartia, is a small (20 to 30'), dense, somewhat pyramidal tree that maintains an upright character into old age. A 35' tall tree, with a *P. calleryana* outline and superb bark at Hillier, 1999. The dark green leaves may turn excellent red to reddish purple in fall although I have seen trees with little color and others that were spectacular. The white, 3" diameter, 5- to 6-petaled, yellow-stamened flowers occur on 3/4" long, glabrous pedicels in June–July. The flowers tend to be flattened rather than cup-shaped and appear over a long time period. The best feature is the rich, flaky bark that, in spite of what the books say (reddish brown) ranges from soft grays and browns to orangish brown with often all colors intermingled on the same tree. In my mind this species is fairly similar to *S. pseudocamellia* and the differences are, at best, slight. The nomenclature is cloudy on a good day with *The New RHS Dictionary of Gardening* listing the taxon as *S. pteropetiolata* Cheng. var. *koreana* (Rehd.) Sealy; Hillier's *Manual* (1991) lists it as *S. pseudocamellia* var. *koreana* (Rehd.) Sealy; Hillier's *Manual* (2002) places *S. koreana* in the Korean Group; RHS Plant Finder 2008–2009 used Korean Group; GRIN lumps it with *S. pseudocamellia* Maxim.; the few plants of *S. pteropetiolata* I observed were evergreen and looked nothing like *S. pseudocamellia* or *S. koreana*; recently (2007) witnessed *S. pteropetiolata* Cheng treated as a semi-evergreen species, leaves glossy dark green, soft bristly stems, white about 1 1/2" diameter flowers, from Yunnan, introduced 1912. Spongberg treated it as *S. pseudocamellia* 'Korean Splendor', a seedling cultivar (legitimate under rules of nomenclature for cultivated plants) with more saucer-shaped flowers, orangish fall color, pronounced flowers in June–July. This designation is somewhat difficult to accept based on plants of *S. koreana* that I have observed. Consistently, nurserymen, Bill Flemer and Don Shadow most notably, indicated *S. koreana* is more heat tolerant. Cappelletto reported the plant hardy in Orono, ME. I have observed this particular plant in the Littlefield Garden during visits to Maine. Korean literature, *J. Korean Applied Ecology* 7(2):112–117 (1994) discusses its rarity in Korea while *J. Korean Soc. Hort. Sci.* 34(2):160–166 (1993) reports on seed (3,000 ppm GA soak for 24 hours at 77°F in dark, followed by 3 months warm, then 3 months cold produced best germination) and cuttings (3,000 ppm IBA, June 12 cuttings, 90% rooting; later collection dates correlated with decreased rooting). E.H. Wilson introduced this species from Korea in 1917. Zone 5 to 7. Trees from Mt. Sobaek, North Korea, survived –18°F. See *J. Korean Soc. Hort. Sci.* 33:413–424 (1992).

***Stewartia malacodendron* L.**— Silky Stewartia
(stū-är'ti-a mal-a-kō-den'dron)

LEAVES: Alternate, simple, elliptic to elliptic-oblong, 2 to 4" long, acute or short acuminate, cuneate, serrulate and ciliate, dark green and glabrous above, light green and pubescent beneath; petiole—1/4" long, pubescent.

Stewartia malacodendron, Silky Stewartia, is a southeastern United States native found principally in the Coastal Plain. Herbarium sheets I checked noted that it is found on the side of streams but also in drier areas. The habit is that of a large shrub or small tree growing 10 to 15'(18') high. There was a fine

specimen at Biltmore Estate, Asheville, NC; have seen the plant in Savannah, GA performing well. The 2 1/2 to 3 1/2"(4") diameter, 5 white-petals, 5 sepals, purple-filamented, blue-anthered flowers appear singly from the leaf axils in July and August (June, Asheville, NC). Flowers fully expressed early May in Athens. The fruit is a woody, egg-shaped, 1/2" diameter, 5-valved, beaked capsule and the lustrous brown seeds are wingless. The bark is gray-brown, similar to that of *S. ovata*, not effective compared to *S. koreana*, *S. pseudocamellia*, *S. monadelpha* and *S. sinensis*. Differs from *S. ovata* in leaf shape and the united styles. This is a finicky species to culture and I have failed on multiple occasions with the species. To witness the flowers, is to understand the quest. The late Dr. Wilbur Duncan, Emeritus Botanist, Georgia, brought a flowering branch from his garden plant to my office in May 1997. After composing myself and bringing the heart beat to normal, I grabbed the camera and captured the flowers. Tremendously susceptible to root rot, so plant high, mulch, provide even moisture and semi-shade (pine). Magnificent specimens, 18' by 15' at Hillier; 20' at Wisley; flower buds evident in late April, formed on old wood, full flower (no fragrance), early to mid June, 1999; the Hillier tree with wine-red staining at the petal bases, absolutely magnificent in flower. Noted 'Beaver Creek' with 3 to 3 1/2" diameter flowers, purple stamens, easy to propagate, fast grower, listed by the nursery of the same name. Did not see it in the 2007 guide. Virginia and Arkansas to Florida, Louisiana and Texas. Cultivated 1752. Zone (6)7 to 9; survived -17°F at Biltmore.

Stewartia monadelpha Sieb. & Zucc. — Tall Stewartia
(stū-är'ti-a mon-a-del'fa)

LEAVES: Alternate, simple, elliptic to oblong-elliptic, 1 1/2 to 3" long, 5/8 to 1 1/2" wide, acute, rounded or broad cuneate, finely serrate, dark green above, somewhat lustrous, grayish green and pubescent below; petiole—1/2" long.

BUDS: Imbricate, brown, silky hairy, compressed, 1/4 to 3/8" long, 3 to 4 scales visible, stalked or tapering to narrow base, broadest in middle, oblique to leaf scar, borne at 30 to 45° angle to stem.

STEM: Distinctly zig-zag, brown, pubescent, vertical fissures in epidermis; pith—green, solid.

Stewartia monadelpha, Tall Stewartia, was little more than an afterthought until the 5th edition, but after observing it in the Middle Atlantic States and Southeast, I believe gardeners should consider growing this instead of *S. pseudocamellia*. A 15' high plant in the Dirr garden provided tremendous satisfaction. The habit is pyramidal, rounded and almost shrubby although older trees at Callaway Gardens are more open and horizontally branched and about 20 to 25' high after 30 plus years. Literature lists size in the wild as 75 to 80' high. The dark green leaves have developed outstanding deep reddish, almost maroon fall color about 1 out of every 4 years in our garden. The leaves hold into early December and may be killed at 20 to 25°F. The bark is given short shrift in most references but in youth is rich brown and scaly. The scales are small and exfoliation is not as manifest as on *S. pseudocamellia*. However, with age, the older trunks become rich, almost cinnamon brown and smooth. I can focus in on this species more easily by bark than many of the other species. Interestingly, the species displays *excellent* heat tolerance and should be considered for northern and southern gardens. The flowers are the smallest of the species treated herein, being 1 to 1 1/2" wide, white with yellowish stamens. Each flower is subtended by large leafy bracts. Flowers tend to remain cupped and do not open as wide as *S. koreana* and *S. pseudocamellia*. Flowers open over 4 weeks starting in early June in our garden. Fruit is a small, 5-valved, 1/2" long, woody, beaked capsule covered with appressed pubescence. Best in partial shade but will take full sun. Several Georgia field growers have tried *S. pseudocamellia*, *S. koreana* and *S. monadelpha* with only the last growing to the degree it was salable. Remarkable specimens with ancient, architectural trunks almost paralleling the ground at Trewithen in Cornwall, England. I had never observed plants as large and could not persuade myself that they were *S. monadelpha*. Japan. Cultivated 1903. Zone (5)6 to 8.

Stewartia pseudocamellia Maxim. — Japanese Stewartia
(stū-är'ti-a sö-dō-ka-mēl'i-a)

LEAVES: Alternate, simple, elliptic or obovate-elliptic to elliptic-lanceolate, 2 to 3 1/2" long, acuminate, cuneate, remotely crenate, serrulate, thickish, dark green and glabrous above, medium to dark green and glabrous or with scattered long hairs below; petiole—1/8 to 3/8" long.

Stewartia pseudocamellia, Japanese Stewartia, is a magnificent small to medium-sized, pyramidal-oval tree. The mature landscape size is 20 to 40' but, in the wild, it will grow 60' high. Mature, mind-altering, 50' high tree, with massive trunk, at Trewithen, March 13, 1999. The medium to dark green leaves may turn yellow, red to dark reddish purple in fall. Leaves emerge before *S. monadelpha* and *S. sinensis*, 50% normal size by April 12, 1999 at Hillier. The 2 to 2 1/2" diameter, broadly cup-shaped, white flowers with white filaments and orange anthers occur in July. Fruit is a broad-ovoid, 3/4 to 1" long, hairy, 5-valved capsule. This is a worthy tree for the garden and is commercially available. Several fine specimens at the Dawes Arboretum have withstood -22°F. The plant pretty much speaks for itself with maturity. The bark is outstanding and develops a rather sinuous, muscled character with the wonderful exfoliating bark fragments painting a lovely portrait. The bark is much like that of *S. koreana* and provides excellent winter color. As I write this I reflect on beautiful specimens at the Arnold Arboretum, Hershey Gardens, Swarthmore . . . each an individual. 'Ogisu' was listed by Costin Nursery, Ireland as a precocious, early-flowering form with cup-shaped, white flowers and attractive, flaking bark. As mentioned under *S. ovata*, I have reservations about the species' performance in Zone (7)8. Japan. Introduced 1874. Zone (4)5 to 7.

***Stewartia rostrata* Spongb.**

(stū-är'ti-a ros-trä'ta)

LEAVES: Alternate, simple, to 6" long, to 2 1/2" wide, serrated, lustrous dark green; petiole—short.

Stewartia rostrata was first witnessed by the author along the Chinese Walk at the Arnold Arboretum. A large, upright shrub to 15' (40' in the wild) with gray-brown, ridged-and-furrowed bark similar to *S. ovata*. The emerging flower buds are surrounded by large, reddish tinged bracts. The white flowers average 2 to 2 1/2" diameter and flowered on May 30, 1991 at the Arnold. It was the first species to open. Flowers fully open May 12, 2005 at the Raulston Arboretum. The overall appearance and flower are more like the American species, but more easily cultured. A pink selection, i.e., pink markings on the flowers, has been offered by Camellia Forest Nursery. Appears more heat tolerant than *S. koreana* or *S. pseudocamellia*. Eastern China. Introduced 1936. Zone 6 to 7.

***Stewartia sinensis* Rehd. & Wils. — Chinese Stewartia**

(stū-är'ti-a sī-nen'sis)

LEAVES: Alternate, simple, elliptic-obovate to oblong-elliptic, 1 1/2 to 4" long, 5/8 to 1 3/4" wide, acuminate, cuneate or rarely rounded, remotely serrate or crenate-serrate, medium green and glabrous above, bright green below; petiole—1/8 to 1/4" long, hairy.

BUDS: Imbricate, about 3 scales visible, reddish brown, covered with silky appressed pubescence, 1/4 to 3/8" long, slightly crooked along the long axis, divergent but forming a 20° angle with the stem, imagination allows one (me) to equate the buds with *Carpinus betulus* in terms of shape, but never touching the stem as in that species.

STEM: Zig-zag, brown, densely pubescent, almost villous-hispid, the hairiest young stems of any *Stewartia*, cut stem bright lime green; pith of the same lime color, appearing excavated, bruised stem malodorous, older stem with epidermal fissuring and cracking.

Stewartia sinensis, Chinese Stewartia, is a small (15 to 25') tree or large shrub with a rich, smooth, light tan-white bark. Thirty to 35' high trees observed in English gardens. The medium green leaves may turn reddish in fall but the few trees I have observed were a subdued reddish and certainly not the rich crimson as described in some references. This is a delightful small landscape plant that should be more widely used. The white, fragrant, cup-shaped, 1 1/2 to 2" diameter flowers are smaller than those of the other species treated here, with the exception of *S. monadelpha*. The ovoid to globose, 5-angled and 5-beaked, 3/4" wide capsule is about the largest of the genus. Considerable travel was necessary before I was able to straighten the confusion between this and *S. monadelpha* and, indeed, hybrids between the two species are reported. The bark in the finest form is choice and a plant at Wakehurst Place, England, is my type specimen for comparing all others. Since my Wakehurst encounter of the first kind, the species was rekindled in Rowallane, Northern Ireland, and Trewithen, England. The Rowallane specimen was about 20' by 25', with low-slung branches, the bark exfoliating on 2 to 3" diameter stems to reveal the polished underbark. Once observed, the image remains ingrained and for true gardeners the only hope is to secure a plant. Actually, it is akin to a quest. In 1996, small seedlings that I purchased as *S. sinensis* were actually as advertised. Plants grew 2' in 3-gallon containers. Small plant in the Dirr garden grew contentedly but did not flower. Fall color was orange-red. Leaves on their undersides and stems were quite pubescent. I praise the bark characteristics on *S. monadelpha*, *S. koreana*, and *S. pseudocamellia*, but this is the best! Bean terms the bark "as smooth as alabaster and the color of weathered sandstone" and, indeed, I have stroked the trunk and branches feeling I had touched polished marble. On young plants, the bark exfoliates in relatively long, shiny cinnamon brown sheets, not unlike that of *Acer griseum*. Hardy to Boston and should

be pursued by discriminating gardeners. *Stewartia sinensis* is native to central China. Introduced 1901 by E.H. Wilson. Zone 5 to 7. On occasion, I see *S. gemmata* listed. Modern references list this as synonymous with *S. sinensis*.

ADDITIONAL NOTES: All are wonderful garden plants and are worth seeking. I believe a moist, well-drained, high organic matter, acid soil is important. They have no serious pests and, once established, offer many years of season-long beauty. Stewartias can easily be categorized among the crème de la crème of woody flowering shrubs/trees.

Another species that the collector might want to track is *Stewartia serrata* Maxim. with dull green, incurved, serrated, 1 1/2 to 3" long, 2 to 2 1/2" wide leaves and 1 1/2 to 2" diameter, non-fragrant, creamy white, cupped flowers with yellow-anthered stamens, petals stained red on their outsides. Fruits are maroon-purple. Fall color is dusty reddish purple. Considered similar to *S. monadelphica* but with slightly larger leaves and flowers. Also among the earliest to flower in the spring. Bark is warm brown. Flowers were opening on May 12, still present June 10, 1999 on Hillier trees; each flower cupped with 5 sepals, the corolla abscising intact. Large capsules, 3/4" long, glabrous. Hillier plants were 18 to 20' tall in 1999. Japan. Cultivated 1917. Zone 6.

As a final note, I recommend Spongberg's article on *Stewartia* in the *Journal of the Arnold Arboretum* 55:182–214 (1978) for the true aficionado. Also of more recent vintage is Nicholson's garden treatment of *Stewartia* in *Fine Gardening* 40:49–51 (1994).

STEWARTIA HYBRIDS AND CULTIVARS

With the taxonomy of *S. koreana* and *S. pseudocamellia* muddled, and the lineage of cultivars confounded, I chose to list in alphabetical order the taxa with reported (suspected) parentage.

'Ballet' (*S. pseudocamellia*)—Flowers to 3 1/2" diameter; graceful, spreading branches; orange-brown fall color; Polly Hill introduction.

'Cascade' (*S. pseudocamellia*)—Arching, cascading branches, semi-pendent shoot-tips, 15' by 12' after 30 years; white flowers with golden yellow stamens; rich red-purple fall color.

'Milk and Honey' (*S. pseudocamellia*)—Numerous, approximately 3" diameter, cream flowers on a strong, upright-growing plant as witnessed at Windy Hill Nursery, Great Barrington, MA in late July 1994, beautiful, elegant, heavy-flowered plant; brighter reddish tan bark; literature reported habit as graceful and spreading with flowers to 4" diameter; I have questions, with age possibly; a Polly Hill introduction.

Pink Form (*S. pseudocamellia*)—A light pink-budded form, opens to delicate pinkish white flowers; have observed in flower in early- to mid-May at the Atlanta Botanical Garden, not particularly showy, especially from a distance; may be a *S. rostrata* × *S. monadelphica* hybrid.

'Red Rose', 'Royal Purple', and 'White Satin'—Selections of *S. ovata* by Polly Hill with red stamens, yellow anthers; purple stamens, yellow anthers; and white stamens, yellow anthers, respectively; observed several of Polly's selections during a June visit to the Polly Hill Arboretum; certainly beautiful, the largest stumbling block to garden acceptance is their recalcitrant propagation via cuttings.

'Scarlet Sentinel'—Upright dense habit; white flowers crowned with red-pink (scarlet) stamens; introduced by Dr. Peter Del Tridici, Arnold Arboretum, see *Hortscience* 37:412–414 (2002); hybrid of *S. ovata* var. *grandiflora* and *S. pseudocamellia*, chance seedling, 21.5' by 8.25' in 12 years, gray-brown bark exfoliates in thin strips; 'Harvard Crimson' is listed as a synonym.

'Skyrocket' (*S. xhenryae*)—A vigorous form with 2" diameter flowers and multi-colored bark; difficult to propagate; Polly Hill introduction.

Stewartia xhenryae Li (*S. monadelphica* × *S. pseudocamellia*) is known; I suspect this is the *S. sinensis* that appears on occasion in gardens and arboreta; listed as more compact than *S. pseudocamellia*, large cream-white flowers, excellent fall color, exfoliating bark; noted a plant at Hillier that fit the *S. xhenryae* description with 2" diameter flowers in late June–early July, intermediate leaves, yet the great bark of *S. pseudocamellia*; another tree in Hillier's Brenty Woodland that appeared similar to above was 35 to 40' high, upright tree.

'Variegata'—Described for both *S. pseudocamellia* and *S. monadelphica*; I have yet to see; also observed weeping and dwarf selections.

Styphnolobium japonicum (L.) Schoit (formerly *Sophora japonica* L.) — Japanese

Pagodatree, often called Scholar-tree

(so-fō'ra ja-pon'i-ka)

FAMILY: Fabaceae or Papilionaceae

LEAVES: Alternate, pinnately compound, 6 to 10" long, 7 to 17 leaflets, ovate to lance-ovate, 1 to 2" long, half as wide, acute, broad cuneate to rounded at base, entire, bright to medium green and lustrous above, glaucous beneath and closely appressed-pubescent.

BUDS: Blackish, woolly, sessile, indistinctly scaly, concealed by the leaf scar, end bud lacking; base of rachis swollen and enclosing bud.

STEM: Slender, essentially glabrous, green on 1- through 4- and 5-year-old wood, grayish lenticels, nodes prominently protruding; pith—solid, greenish.

SIZE: 50 to 75' in height with a comparable spread although great variation occurs.

HARDINESS: Zone 4 to 7, hardy in Orono, ME.

HABIT: Usually upright-spreading with a broadly rounded crown at maturity; casts a relatively light shade; many seedling trees were planted on the Georgia campus and are rather open the first 2 to 3 years but form a decent canopy in the 4th and 5th years, same trees in serious decline.

RATE: Medium to fast, 10 to 12' in a 5 to 6 year period; has been faster than this in Zone 7, probably 3' per year the first 5 years.

TEXTURE: Medium-fine in leaf; medium in winter.

BARK: On old trunks somewhat Black Locust-like except pale grayish brown in color.

LEAF COLOR: Lustrous bright to medium green in summer; green color holds late and little fall color develops; on occasion soft yellow fall color; I have trouble with the shade of green, looks more bright green than anything.

FLOWERS: Perfect, creamy white, mildly fragrant; borne in 6 to 12" long and wide terminal panicles (have measured them 12" high and 14" wide) in July through mid-August; each flower 1/2" long, calyx 1/8" long, green, bell-shaped, very showy in flower; flowered in July in Boston.

FRUIT: Pod, bright green changing to yellow and finally yellow brown, 3 to 8" long, constricted between seeds, 3- to 6(10)-seeded; October, and may remain all winter; after the pods abscise the infructescence remains.

CULTURE: Transplant balled-and-burlapped as a young specimen; prefers loamy, well-drained soil; actually somewhat tender to cold when young but once over 1 1/2" caliper seems to be fine; once established withstands heat and drought well; also tolerant of polluted conditions; prune in fall; tends to be a "floppy" grower and is somewhat difficult to train into a central leader with a nice head; the literature is full of comments about the lateness to flower, i.e., needs to grow 10 years or more; 3- to 5-year-old trees have produced heavy crops of flowers and fruits; perhaps most impressive has been the growth rate in the Southeast, probably 3' per year during the first 5 years after transplanting; more urban tolerant than given credit; a number of plantspeople are taking a closer look at its attributes; with the 6th edition I bear somber news that the trees planted in the 1980's on the Georgia campus are suffering from canker, dieback, general malaise and simply have not performed well over time in Zone 7. Most have perished (2008).

DISEASES AND INSECTS: Canker, damping-off of seedlings, twig blight, powdery mildew and leaf hoppers; the potato leaf hopper can kill young stems and this in turn results in a "witches' broom."

LANDSCAPE VALUE: Good tree for city conditions, lawns, poor soil areas, parks, golf courses; probably best in Zone 5 and 6; excellent flower and good foliage are principal assets; could be considered messy for petals, fruits, leaves, rachises and pods drop differentially; flowers create a creamy carpet under the tree for a time in July–August; in Europe, the species is consistently rated among the highest for pollution and urban tolerances; planted a number at Milliken Arboretum in 19990 and most were still alive in 2008; as discussed under CULTURE, probably not a forever tree in the Southeast but the soft green foliage and cream-white flowers are certainly desirable attributes; had the great fortune to touch the magnificent venerable specimen in Edgartown, Martha's Vineyard, MA; amazing 80 to 90' high tree, perhaps larger, growing along the street.

CULTIVARS:

'Columnaris' ('Fastigiata')—Upright growth habit, have never observed but young trees often show an upright outline.

Millstone™ ('Halka', PP 7,554)—Uniform, broad oval to rounded, branching symmetrical and upswept, 45' by 35'; lustrous dark green leaves; cream-white flowers; less susceptible to stem canker than the species; Halka Nursery introduction.

'Pendula'—Weeping form, seldom flowers, quite interesting when used as an accent or formal specimen; comes relatively true-to-type from seed; I have collected seed from a plant at Bernheim Arboretum and a surprising number of the seedlings exhibited various degrees of pendulousness, about 1:1 ratio; my only regret is I gave them to my friends and did not save one for my garden; often grafted on a standard, will grow 15 to 25' high; was a great old specimen at Mainau, Germany.

Princeton Upright® ('Fleright', PP 5,524)—All the good qualities of 'Regent' with a compact upright branching system, 40 to 50'.

Regent®—Selection by Princeton Nurseries for fast growth rate, often twice the rate of seedling trees, straight growth habit, large oval-rounded crown, glossy deep green leaves, and earliness to flower

(6- to 8-years-old); in Zone 7 this occurred after 1 to 3 years in the nursery; good plant and it flowers heavily in the Athens area; 50' by 45'.

'Variegata'—White speckled leaves; saw for the first time in Berlin Botanic Garden; for the dedicated collector; 30' by 30' plant at Hillier in 1999.

PROPAGATION: Seeds supposedly require a weak scarification in acid to break down the impermeable seed coat, easy to grow from seed; I have grown numerous seedlings by sowing them as soon as they are removed from the pod; worthwhile to soak seeds overnight to prime for more even germination; cultivars are budded.

ADDITIONAL NOTES: Last of the large ornamental trees to flower in the North. Used around Buddhist temples. Yellow dye can be extracted from the flowers by baking them until brown and then boiling them in water. A very distinctive and aesthetically handsome tree in flower. Bean mentioned that the tree does not flower until 30 to 40 years of age. American references have stated 10 to 14 years. I have a sneaking suspicion that high summer heat, perhaps warm nights, foster early flowering. All authors, including this one, tend to pass along time-honored information without determining, first hand, the actual response in question.

About 50 species between *Styphnolobium* and *Sophora*, with only *Styphnolobium japonicum* and *Sophora secundiflora* of garden importance in the United States. Several that I witnessed in flower, all quite attractive, include: ***Sophora davidii*** (Franch.) Skeels, (so-fō'ra dā-vid'ē -ī), shrub-like with spiny branches with 7 to 10 leaflet pairs, each leaflet 1/4 to 2/5" long, oval or obovate, gray hairs below; and bluish white flowers in 2 to 3" terminal racemes in June (June 14, 1999, Kew), 6 to 12 flowers per raceme; growing at Coker and Raulston Arboreta; Zone 6 to 7; southwest China, introduced 1897. ***Sophora flavescens*** Ait., (so-fō'ra flā-ves'sens), is a shrub to 5' with 6 to 9" long leaves composed of up to 19, narrow-ovate, 1 1/2 to 2 1/2" long green leaflets; foliage is attractive; yellow-white flowers in up to 12" long racemes in June–July; China; Zone 6; succeeded in Raulston Arboretum. ***Sophora microphylla*** Ait., (so-fō'ra mī-krō-fil'a), is a large evergreen shrub/small tree, quite dense in habit, with up to 30 pairs of dark green, 1/3" long leaflets. Flowers are rich yellow, 1 to 1 3/4" long in racemes, noted yellow flowers on April 13, 1999 at Hillier, plant with minimal leaves (not totally evergreen), flowers smaller than Sun King™. Sun King™ ('Hilsop') proved one of my favorite new plants at Hillier as I observed flowers starting to emerge on February 2, still flowering June 7, 1999. This more cold hardy, evergreen selection of Chilean origin was 10 to 12' high, densely foliated and extremely eye-catching. The plant had grown in the Hillier Arboretum for a long period and its aesthetic merits were recognized and commercialized. It was in most of the garden centers I visited in 1999. 'Dragon's Gold', 'Earlygold', and 'Goldilocks' are listed. A closely related species, ***Sophora tetraptera*** J.F. Mill., (so-fō'ra te-trap'ter-a) has 20 to 40 ovate to elliptic-oblong leaflets and yellow, about 2" long, tubular, pea-shaped flowers in May. Pods are beaded with 4 broad wings, hence, tetraptera. Zone 8. New Zealand, Chile, introduced 1772. *Sophora microphylla* is native to New Zealand, Chile. Zone 8. Both species best suited to Zone 8 to 10 on West Coast. ***Sophora koreensis*** Nakai (so-fō'ra kor-ē-en'sis) is a half-hardy to herbaceous perennial with rich green, compound pinnate leaves and large racemes of showy, yellow flowers in March–April. Flowered March 23, 2006 at Raulston Arboretum. Grows about 3' high and wide. Have only observed at the Raulston Arboretum. Zone 7.

NATIVE HABITAT: China, Korea. Introduced 1747.

RELATED SPECIES:

Sophora secundiflora (Ort.) Lag. ex DC. (now *Calia secundiflora* (Ort.) Yakovlev) — Mescal Bean, Texas Mountain Laurel (so-fō'ra sē-kund-i-flō'ra)

LEAVES: Alternate, evergreen, compound pinnate, 4 to 6" long, 6 to 10 leaflets, to 2" long, oblong or obovate, notched at apex, pubescent below, rich green.

Sophora secundiflora, Mescal Bean, is a small, (15') 20 to 30' high, evergreen tree with great foliage and branch character. The habit is irregular, upright-spreading, low-branched. Co-national champions are 35' by 18' in Uvalde, TX and 19' by 27' in San Antonio, TX. The fragrant, 1" long, violet-blue flowers occur in pendent racemes. Fruits are 6 to 8" long, woody pods. Requires well-drained, drier soils and is best suited to the Southwest. I first saw the plant in a street side planting in San Antonio, TX. Holds up well under stress. Too much care (read water) will kill it. 'Alba', with white flowers, is described. 'Calia' has glaucous, dusty blue leaves that hold the color year-round in Zone 7; foliage is extremely attractive. Seeds germinate best after two hour concentrated sulfuric acid scarification. See *HortScience* 26:256-257 (1991). See *Nursery Manager* 11(12):14-15, 69 (1995) for a worthy discussion. Texas, New Mexico, northern Mexico. Zone 8 to 10.

Styrax japonicus Sieb. & Zucc. — Japanese Snowbell

(stī'raks ja-pon'i-kus)

FAMILY: Styracaceae

LEAVES: Alternate, simple, broad-elliptic to elliptic-oblong, 1 to 3 1/2" long, 1/2 to 1 1/2" wide, acute to acuminate, cuneate, remotely denticulate to almost entire, medium to dark green and often lustrous above, glabrous, with axillary tufts below; petiole—1/3" long.

BUDS: Small, sessile, naked, scurfy, superposed, 1/6 to 1/4" long.

STEM: Rounded, zig-zag, rough-scurfy, light brown; pith small, rounded, continuous, green; leaf scars 2 ranked, at first torn, narrow, and shriveled, finally broadly crescent-shaped.

SIZE: 20 to 30' in height and of a comparable or greater spread.

HARDINESS: Zone 5 to 8, injured at -20°F, very few flowers opened, wood was not killed; killed in Orono, ME.

HABIT: A lovely, small, low-branched tree which develops a rounded to broad-rounded crown and a distinct horizontal appearance because of the wide-spreading branches; a very dainty tree which will grace any landscape.

RATE: Medium, 9 to 10' over a 7 to 10 year period; I grew this at Illinois and with proper water and fertilizer it averaged 2 to 3' per year in youth.

TEXTURE: Medium-fine in leaf; medium in winter.

BARK: Quite handsome gray-brown of smooth consistency but showing irregular, orangish brown, and interlacing fissures; excellent addition to winter landscape.

LEAF COLOR: Medium to dark green in summer, often lustrous, unusually pest-free; changing to yellowish or reddish in the fall; foliage is borne on the upper part of the branches and does not significantly detract from the flowers which are pendulous; I have not seen good fall color on this species; leaves emerge early, evident by late March in Athens, and can be rendered toast by a late freeze; leaves hold late and are often killed by an early freeze; some yellow fall color on various accessions in the UGA trials.

FLOWERS: Perfect, 3/4" wide, white, yellow-stamened, slightly fragrant, bell-shaped, corolla 5-lobed being united near base, each flower borne on a 1 to 1 1/2" long pendulous stalk, occurring on short lateral shoots, each with 3 to 6 flowers, May–June and of great beauty. Full flower May 13, 2005 at Sarah P. Duke Gardens. I have always considered this a most beautiful and delicate flowering tree yet is not well-known outside of arboreta and botanical gardens.

FRUIT: Dry drupe, ovoid, about 1/2" long, grayish in color and less than obvious; effective in August and often falling by November; containing a single shiny brown hard seed.

CULTURE: Transplant balled-and-burlapped or from a container in early spring into a moist, acid, well-drained soil which has been abundantly supplemented with peat moss or organic matter; full sun or partial shade; prune in winter; site carefully in cold climates; probably best in partial shade in Zone 7 and 8; our experience with bare-root plants has been up and down, almost always some tip dieback.

DISEASES AND INSECTS: Dr. Darrel Apps mentioned a borer that had devastated plants in the Philadelphia area; have observed Ambrosia beetle damage and canker on field-grown nursery stock; Tubensing, *American Nurseryman* 172(4):145 (1990), reported serious damage to this and *S. obassia* from Ambrosia beetle, *Xylandras germanus*; have seen more canker-like injury in recent years—bark is thin and perhaps mechanical injury predisposes plants to more infection; trees often slow to leaf after difficult winter—late spring freezes; I suspect some degree of cambial damage.

LANDSCAPE VALUE: A handsome small tree for many situations; excellent near the patio, in the lawn, or in the shrub border; it is another of the unknown trees that is worthy of extensive landscape use; Bean called it a tree of singular grace and beauty; can be planted on hillsides or slopes where the flowers are seen firsthand by passersby; the leaves are perched like butterflies on the upper part of the stem so the pendulous flowers are not masked; have utilized on the Georgia campus in significant numbers and plants in full sun without supplemental water have suffered, leaves abscise or at best crisp on their margins; in 30 years at Georgia, the species has been tried three times in our garden and perished unabashedly; the only survivor was 'Emerald Pagoda' and it perished in 2002.

CULTIVARS: Several handsome and unusual cultivars in the United States and should now be available to the gardening public.

'Angyo Dwarf'—8 to 10', white, slightly fragrant flowers; collected by Barry Yinger in Japan in 1978, introduced by Brookside Gardens.

Benibana Group—Soft pink flowers, floriferous in youth, 4-year-old plants flowered; 10' by 8', also considered the umbrella name in Japan for all pink-flowered, seed-grown forms.

'Crystal'—Dark green leaves; white flowers with purple pedicels and sepals, 2 to 9 petals; vigorous grower, somewhat upright fastigiate habit; from JC Raulston Arboretum, selected from seedlings of Korean origin.

'Emerald Meadow'—More upright pyramidal habit, 20 to 30' by 15 to 25'; larger, darker green leaf; Gary Handy introduction.

'Emerald Pagoda' ('Sohuksan')—Introduced in 1985 by the late Dr. JC Raulston and U.S. National Arboretum collecting team from Korea; the plant and leaves are larger, more leathery and darker green than typical, flowers are also larger; this is a tremendous selection and displays significant heat tolerance; plant is upright, vase-shaped in youth; flowers have variable petal numbers (2 to 8) with great substance and are up to 1" diameter, has flowered in early- to mid-April in Athens; lost the tree in the Dirr garden, other gardeners had similar experience; a large tree in the Raulston (2007) has extensive bark damage, almost canker-like, may be injury from either early fall freezes or late winter-spring freezes; I rated this one of Dr. Raulston's best introductions and I believe he thought likewise; truly magnificent plant when right.

'Fargesii'—Large leaves, flowers two weeks later than typical species, thick dark green leaves; green-purple pedicels that accent the pure white flowers; tree-like habit, a 25' high tree at Wisley in 1999; I have seen this listed as variety *fargesii*.

'Fragrant Fountains' (PP 19,664)—More graceful, tree-like form; only witnessed the plant in large containers; stiff main stem with graceful arching side shoots; lustrous dark green leaves; fragrant, white flowers; 12' by 7'; more upright and vigorous than 'Carillon'; Crispin Nursery introduction; seedling of 'Rosea' possibly pollinated by 'Carillon'.

'Frosted Emerald'—Leaves with white margin and green center few plants I observed did not appear robust; will revert; requires partial shade; Crispin Nursery Introduction.

'Issai'—Free-flowering selection; fast-growing, 20 to 30' high; selected by Barry Yinger from Japan, distributed by Brookside Garden.

'Kusan'—A compact, globe-shaped form about 11' high in 10 years, similar spread; flowers young; found by Bob Tichnor, retired, Oregon State University.

'Pendula' ('Carillon', 'Carilon')—A small (8 to 12') weeping tree with foliage and flowers similar to the species; I have seen one of the early introductions and am quite impressed by the general refined nature and gracefulness; tends toward a stiff, arching, decurved-branching habit, not quite as graceful as I envisioned; I believe 'Carillon' ('Carilon') is a rename of 'Pendula'; introduced by Brookside Gardens, Wheaton, MD.

'Pink Chimes'—Offers pink flowers on an upright shrub or small tree; lovely the one year it flowered in our garden, typically late April-early May in Athens; that winter I took the easy way out and burned the herbaceous plants in the same bed, the bark and a hot fire did not mix, to which I say never plant Armitage's herbaceous litter next to a good woody plant; Benibana Group.

'Purple Dress'—Not much to go on except minimalist photo and description . . . purple leaves (except photo shows green with purple suffusion on upper surface), pink flowers, grows to about 25'.

Reed Hybrids—Dr. Sandra Reed, USDA-USNA, has produced several selections that are being tested in Georgia; the 71587 clone has lustrous black green leaves, tight conical habit and performed superbly in the Georgia trials; 2007 and 2008 were two of the hottest and driest years on record and this clone (3 plants) stood firm; abundant slightly fragrant flowers; grew 10' by 4 1/2' in 4 1/2 years; 2 others, 71589 and 71590 are genetically compact, upright types that did not flower well and lack substance.

'Rosea'—A clear pink-flowered form that occurred as a bud sport, the parent plant was only 4' high and the growth habit somewhat upright; perhaps same as 'Pink Chimes', although 'Pink Chimes' grows into a small tree; have observed a pink-flowered, weeping form at Atlanta Botanical Gardens; Dr. Werner, former director, Raulston Arboretum, mentioned a deeper pink, weeping form; Benibana Group.

'Ryan's Weeper'—Slow growing, delicate, graceful weeper; more compact than 'Pendula' ('Carillon'); dark green leaves with dark stems; Gary Handy introduction.

Snow Charm® ('JFS-E')—Rounded habit, 20' by 20'; dark green leaves, larger than Snow Cone®, yellowish in fall; typical white flowers; resistant to twig dieback which is common after transplanting; J.F. Schmidt & Son, Co. introduction.

Snowcone® ('JFS-D')—Symmetrical, broad pyramidal habit, dense, 25' by 20'; tree in Schmidt Arboretum was a perfect pyramid; fine-textured, dark green foliage; white flowers; resistant to twig dieback; J.F. Schmidt & Son, Co. introduction; observed in Schmidt's production fields in late August, handsome outline and foliage.

'Snowfall'—More dense and rounded habit; prolific slightly fragrant flowers; selected from a superior plant on the NCSU campus, released via JC Raulston Arboretum.

I have also heard of double-flowered, variegated, dwarf, contorted and red-flowered forms.

PROPAGATION: Seeds exhibit a double dormancy and warm stratification for 5 months followed by cold for 3 months is recommended; I have germinated seeds of *S. obassia* but they proved to be doubly dormant and after several transfers from warm to cold to warm to cold to warm finally secured a modicum of seedlings. Seeds could be fall sown and germination will take place the second spring; if collected fresh and sown immediately they may come up the next spring. Dr. Josh Kardos, PII, reports that seeds of an unnamed clone received 90 days warm/90 days cold stratification. Seeds were then sown on April 3, 2008 and seedlings transplanted May 1, 2008. Seeds of 'Roseus' were given a 90 day warm/110 day cold stratification and sown on April 29, 2006 but did not germinate until the next year, the seed flat was left outside through the 2006–2007 winter; 10 to 20% of the 'Roseus' seedlings flowered the first year after transplanting. Softwood cuttings, treated with IBA will root readily under mist; *S. obassia* rooted well when collected in mid-July. *Styrax americanus*, *S. japonicus*, and *S. obassia* are extremely easy to root from softwood cuttings; about 1,000 to 3,000 ppm IBA-quick dip, peat:perlite, mist proved optimum. However, like *Stewartia*, the rooted cuttings are not easy to overwinter. Tissue culture was successful with *S. japonicus*.

ADDITIONAL NOTES: Meyer, *Arnoldia* 52(1):2–8 (1992), describes "The Snowbells of Korea."

NATIVE HABITAT: China, Korea, Japan, Philippines, Ryukyus, and Taiwan. Introduced 1862.

RELATED SPECIES:

***Styrax americanus* Lam. — American Snowbell**

(stī'raks a-mer-i-kā'nus)

LEAVES: Alternate, simple, narrow oval to obovate, 1 1/2 to 3 1/2" long, 1/2 to 1 1/4" wide, acute or acuminate, cuneate, entire or serrulate, bright green, sparingly stellate-pubescent below; petiole—1/8" long.

BUDS: Superposed, larger bud set at an oblique angle to stem, 1/16 to 1/8" long, quite similar to *S. japonicus* in overall morphology.

STEM: Slender, light brown, glabrous or slightly scurfy, zig-zag, developing stringy condition; pith—green, solid.

Styrax americanus, American Snowbell, is a small, slender-stemmed, rather wispy, 6 to 8'(10') high rounded shrub. The bright green leaves do not develop any significant fall color. The beautiful white, bell-shaped flowers with highly reflexed lobes hang from the leaf axils in May or June. Flowers late April–early May in Athens; May 30, 1991 in full flower at the Arnold Arboretum; June 1–10, 1999, Hillier. Each 5-petaled flower is 1/2 to 3/4" long, 3/4 to 1 1/4" wide, produced 1 to 4 at the ends of short branches on 1/4 to 1/2" long pedicels. The petals are quite narrow, usually about 1/4" wide. The 1/3" long, obovoid, grayish pubescent drupe develops in August–September. I consider this a beautiful shrub and if given a cool, moist, acid root run will reward the gardener many-fold. It is found in the wild in lowlands bordering streams. I have found it along streams around Athens. In this situation, it looks rather forlorn but when freed from competition it makes a fine garden shrub. Extremely easy to root from softwood cuttings in June–July. Seeds sown in fall will germinate the following spring. Variety *pulverulentus* (Michx.) Perk. (separate species according to some) has more pubescent leaves. Duncan, *Trees of the Southeastern United States*, reduces *S. pulverulentus* into synonymy. Virginia to Florida, west to Missouri, Arkansas and Louisiana. Introduced 1765. Zone 5 to 9, although some tip dieback may occur in severe winters.

At Knightshayes, witnessed *Styrax dasyanthus* Perkins, 25' by 25', elongated 2 to 4" long leaves, smooth above, glaucous below, sharply serrated, with white flowers, petals reflexed like *S. americanus*. China. Tender, Zone 8 to 9? Best on West Coast.

***Styrax grandifolius* Ait. — Bigleaf Snowbell**
(stī'raks gran-di-fō'li-us)

LEAVES: Alternate, simple, elliptic to obovate to orbicular, 2 1/2 to 7" long, 1 1/2 to 3 3/4" wide, short acuminate, cuneate, denticulate or almost entire, dark green above, grayish tomentose below; petiole—1/4 to 1/2" long.

Styrax grandifolius, Bigleaf Snowbell, is found along the banks of streams from Virginia to Florida, west to Missouri, Arkansas and Texas. I have discovered it mixed in the understory with *Kalmia* in the Piedmont of Georgia. Typically occurs as an understory shrub/tree in deciduous or mixed woods, usually in well-drained soils. Have observed in dry woods on slopes around Chapel Hill, always in the understory. The habit is small-tree to shrub-like. Size ranges from 8 to 12'(15') in height. National champion 16' by 16' in Buncombe, NC. The leaves remind of *S. obassia* and range from 2 1/2 to 7" long. The beautiful white, fragrant, 3/4 to 1" wide flowers occur in 7- to 12(20)-flowered, 4 to 8" long, nodding racemes in May–June. This would be a good choice for southern gardens but is not commonly available from nurseries. Not as "tough" as *S. obassia* and for that reason tends to labor in obscurity. Has flowered in the Georgia trials but is rather tatty by summer's end. Have attempted to root May cuttings from a local native population but with no success. Introduced 1765. Zone (6)7 to 9.

***Styrax obassia* Sieb. & Zucc. — Fragrant Snowbell**
(stī'raks ō-bās'ē-a)

LEAVES: Alternate, simple, suborbicular to broad-ovate, 3 to 8" long, from 2/3's to as wide, abruptly acuminate, usually rounded at the base, remotely denticulate above the middle and sometimes tricuspidate at apex, glabrous and dark green above, densely pubescent beneath; petiole—1/3 to 1" long, the base enclosing the bud.

BUDS: Scales enveloping rather than imbricate, tomentose, dirty gray-brown, usually 2 buds at a node, the larger 1/4 to 5/16" long, ovoid and probably floral; the other smaller, 1/8 to 3/16" long, appressed to the larger bud.

STEM: Stout, glabrous, lustrous reddish brown, exfoliating to expose greenish brown inner bark; pith—solid, green; second year smooth, lustrous brown; third year becoming gray-brown and developing prominent fissures.

BARK: Relatively smooth, gray to gray-brown, marked with shallow, vertical fissures; similar to bark of *S. japonicus*, very handsome.

Styrax obassia, Fragrant Snowbell, is a small tree or shrub which develops dense, ascending branches and can grow 20 to 30'. Plants are distinctly pyramidal-oval in youth but become more open and rounded with age. 50' high trees are known. The flowers are white, fragrant, borne in 4 to 8"(10") long, arching-drooping racemes in May–June (mid-April in Athens). Each bell-shaped flower about 1" long. The leaves are dark green and quite large and detract slightly from the quality and intensity of the flowers. The leaves do not generally develop a good fall color however, on occasion, the small tree in our garden turned romantic yellow. The fruit is a 3/4" long, ovoid, dry, pubescent drupe. This species is not considered as hardy as *S. japonicus* although I have observed them in the same collections where temperatures dropped as low as -25°F and both survived. I have noticed that it flowers ahead of *S. japonicus* opening its flowers in late May–early June at the Arnold while *S. japonicus* was in full flower around mid-June. Over the observational years, I have come to the conclusion that *S. obassia* is more cold hardy than *S. japonicus*. More stem damage is evident on *S. japonicus* than on *S. obassia* after a difficult winter. For the past 30 years, *S. obassia* has been a regular fixture in our garden and is one of my wife's and my favorite conversation pieces. Unfortunately, it leafs out early, about early April in Athens, and is injured 1 out of 3 to 4 years, the leaves being rendered potato-chippy and the flowers useless. New growth follows from latent buds and full foliage is realized by June. Also, in fall an early freeze

can render the leaves crispy gray-brown before their time. Architecturally, the smooth gray branches with numerous twists, turns and sinuations are handsome for winter effect. The flowers are also interesting as they appear to peek out from under the large leaves on slightly curve-shaped racemes that open from the base to the apex over a 2 to 3 week period. Ideally provide ample moisture and high organic matter soil in partial shade, although full sun is acceptable. The less stress the better for maximizing appearance through the summer months. Raulston reported root rot problems in heavy soils in Raleigh. Creech, *Amer. Nurseryman* 163(5):48–49 (1986), reported that *S. obassia* occurs widely in Northern Honshu and extends into Hokkaido, across the Sea of Japan into Korea and Manchuria. This indicates that *S. obassia* should be more cold hardy than *S. japonicus*. Native to Japan, Korea and Manchuria. Introduced 1879. Zone 5 to 8.

A close relative, ***Styrax hemsleyanus*** Diels, is similar to *S. obassia* except the leaves are not as pubescent and the darker buds are visible, not hidden under the petiole base as in *S. obassia*. Performed reasonably well in Georgia trials but labored in the heat and drought. A 35' high tree grew at Bodnant, June 24, 1999. Zone 6 to 7. Central and Western China. Introduced 1900 by E.H. Wilson.

ADDITIONAL NOTES: I have observed the species listed above and believe that *S. japonicus* is the most aesthetic; experiences with *S. americanus* and *S. japonicus* in my Georgia garden have been less than satisfactory. I had sited them in full sun and obviously partial shade and a cool, moist root run would have served better. At the Arnold Arboretum, *S. americanus* and *S. japonicus* make superb specimens. For additional information see Dirr, "The Exquisite Snowbells," *American Nurseryman* 147(2):7, 8, 87–90 (1978).

Since 1980, numerous plant collectors have ventured into China, Korea, and Japan. *Styrax* species in the United States have increased in numbers with their efforts. About 100 species are known with the greatest concentration in Asia. ***Styrax shiraianus*** Mak. from Japan came into my possession. Also, ***Styrax odoratissimus*** Chapm. ex Benth. a small tree with sweetly scented, numerous, white flowers is offered in American commerce. ***Styrax platanifolius*** subsp. ***youngiae*** (Cory) P.W. Fritsch is a small to medium-sized shrub from Texas and Mexico. Has been hardy in Raleigh, NC. J.C. Raulston was extremely interested in the genus and assembled about 21 taxa in Raleigh. See *Proc. Southern Nursery Assoc. Res. Conf.* 36:305–310 (1991) for excellent capsular treatment of over 30 species. Recently, late April 2007, bumped into ***Styrax wilsonii*** Rehd. which, in flower, appeared similar to *S. americanus*. Typically a shrub with smallish, 1/2 to 1" long, toothed- to 3-lobed-at-apex leaves, glaucous and pubescent below. Western China. Introduced 1908. Zone (6)7 to 8. Could not reconcile what I witnessed was, in fact, *S. wilsonii*.

Sycopsis sinensis Oliv. —Chinese Fighazel

(sī-cop'sis sī-nen'sis)

FAMILY: Hamamelidaceae

LEAVES: Alternate, simple, evergreen, elliptic-ovate to elliptic-lanceolate, 2 to 4" long, 1/3 to 1/2 as wide, acuminate, broad cuneate, entire or remotely toothed above the middle, leathery, lustrous dark green and glabrous above, pale green and glabrous or with scattered pubescence below; petiole—1/3" long, warty.

Sycopsis sinensis is a pretty, glossy-leaved evergreen shrub that grows 10 to 15' high and wide under cultivation. I have seen it used at Disney World, Orlando, FL in mass plantings and informal hedges. Tall, tight, tree-like form, oval in outline, with dense foliage, 15' high at Hillier in 1999. Apparently it is amenable to pruning and would make an excellent screen in warmer climates. The small, yellowish flowers have red anthers and are surrounded by dark reddish brown, tomentose bracts. Flowers open in February–March. Fruit is a 1/3" long, 2-valved, dehiscent, pubescent capsule. Any well-drained soil is acceptable and I have observed plants in full sun in Zone 9. For southern gardens this plant might be worth a longer look. Hardiness is somewhat suspect but plants in Savannah, GA have withstood 10°F with minimal injury. Also, a respectable specimen grows at the U.S. National Arboretum. This clone has experienced –10°F and survived.

A green-yellow variegated form grows at the Raulston, not very showy. An interesting intergeneric hybrid, **×*Sycoparrotia semidecidua*** Endress & Anliker, between *Parrotia persica* and *Sycopsis sinensis* is known. It is a rather loose, arching, semi-evergreen (has been evergreen in my garden), 10 to 15'(20') high shrub or tree with 1 to 5" long, 2" wide, lustrous dark green leaves that, although described as intermediate, tend toward the *Parrotia*

×*Sycoparrotia semidecidua*

parent. Depending on cold, leaves may hold or develop yellow coloration. Nothing spectacular and better termed winter leaf color. Flowers are attractive and occur in February–March along the length of the stems. Full flower on February 20 in Dirr garden. The color effect is reddish brown eventually yellow as stamens develop. Large, 30' high plant at Woodlanders, Aiken, SC, the trunk still smooth gray showing nothing akin to the exfoliating bark of *Parrotia persica*. Certainly not a plant for every garden but does have botanical and horticultural interest. Partial shade and well-drained soil appear ideal. Developed from seed around 1950 in the nursery of P. Schonholzer, Basel, Switzerland. Zone (6)7 to 9. 'Purple Haze' is listed in RHS Plant Finder 2008–2009; newly emerging leaves are bronze-purple, at maturity lustrous green. 'Variegata' has light yellow-green borders to the leaf, more evident in spring, pretty much lost later in season; in fact even new growth, May 12, 2005, requires close inspection to get one excited. *Sycopsis sinensis* is native to central and western China. Introduced 1901 by E.H. Wilson. Zone 7 to 9.

Symphoricarpos albus (L.) S.F. Blake — Common Snowberry (sim-fō-ri-kär'pos al'bus)

FAMILY: Caprifoliaceae

LEAVES: Opposite, simple, oval to elliptic-oblong, 3/4 to 2" long, obtuse, roundish, on shoots often sinuately lobed, dark almost blue-green above, pubescent beneath; petiole—1/8 to 1/4" long.

STEM: Slender, rounded, pubescent; pith—brownish, excavated.

SIZE: 3 to 6' by 3 to 6'.

HARDINESS: Zone 3 to 7.

HABIT: Bushy, rounded to broad rounded shrub with numerous ascending shoots, densely fine and twiggy; tends to sucker and colonize.

RATE: Fast.

TEXTURE: Medium in leaf; however, in winter extremely sorrowful; needs a brush.

LEAF COLOR: Bluish green in summer; no effective fall color.

FLOWERS: Perfect, pinkish, 1/4" long, June, borne in 1 1/2 to 1 3/4" long, terminal spikes on current season's growth, basically inconspicuous.

FRUIT: Berry-like drupe, globose, ovoid to lumpy, white, to 1/2" diameter, September through November; most ornamental asset of this shrub; fruit can persist into winter but is often discolored by a fungus.

CULTURE: Transplants easily, very tolerant of any soil; native on limestone and clay; full sun to medium (heavy) shade; suckers profusely and tends to spread extensively; prune in winter to early spring so current season's growth can produce flowers.

DISEASES AND INSECTS: Anthracnose (two genera affect the host; one causes a discoloration of the fruit, the other a spotting of the leaves), berry rot (fruits turn yellowish or brown and are affected by a soft, watery rot), leaf spots, powdery mildews, rusts, stem gall, aphids, snowberry clearwing, scale and glacial whitefly.

LANDSCAPE VALUE: Not a very valuable plant but fruit can be interesting; useful in shaded situations and for holding banks, cuts, fills; the hybrids and cultivars have greater landscape appeal.

CULTIVARS:

'Constance Spry'—Large, white fruit; listed in the English literature.

var. *laevigatus* (Fern.) S.F. Blake—Taller (6'), leaves larger (to 3" long) and broader, fruit larger and more abundant, vigorous grower; have seen *S. albus* var. *laevigatus* listed as *S. rivularis* Suksd.; the latter is now an invalid name; var. *laevigatus* is considered the western extension from Alaska to California.

'Turesson'—Nodding branches; listed in the English literature.

'Variegatus'—Slow-growing, to 4' high shrub with small, white-margined leaves.

PROPAGATION: Immersion in sulfuric acid for 40 to 60 minutes followed by warm and then cold stratification will assist in breaking seed dormancy; cuttings are extremely easy to root, softwood taken in June, July, August, rooted readily; the entire group roots easily from softwood cuttings.

ADDITIONAL NOTES: The *Symphoricarpos* have limited ornamental value but fruit and shade tolerance are definite assets. Should be used sparingly; however, the cultivar 'Hancock' deserves further use as well as the Doorenbos Group (formerly *S. xdoorenbosii* hybrids). Have observed *S. occidentalis* Hook., Wolfberry, at the Arnold Arboretum and in the Western United States where it is native. The bluish green, somewhat scalloped foliage and the white fruits are handsome. Fruits often discolor (brown) quickly after ripening.

NATIVE HABITAT: Nova Scotia to Alberta, south to Minnesota and Virginia. Introduced 1879.

RELATED SPECIES:

Symphoricarpos* × *chenaultii Rehd., (sim-fō-ri-kār'pos she-nō'ē-ī), Chenault Coralberry, is a cross between *S. microphyllus* × *S. orbiculatus*. The plant is a low-spreading, arching shrub growing about 3 to 6' high. Flowers are pink; fruit is pink or white and tinged pink. 'Hancock' is a beautiful low-growing type with small leaves and good ground cover possibilities, a 12-year-old plant may be 2' tall and 12' wide; have not seen mildew on this form; raised about 1940 at Hancock Nurseries, Cookville, Ontario, Canada. Witnessed a 4' tall plant at Wisley in 1999. Chenault Coralberry fruits differ from those of Indiancurrant Coralberry in that the side away from the sun is white. Zone 4 to 7. The fruit is more rose-red than pinkish as mentioned above but variation exists. The leaves are quite small, dark blue-green, ovate, 1" long and pubescent below. 'Brain De Soleil' (PP 18,567) is a yellow-orange-leaf branch sport of 'Hancock' discovered at Maine et Loire, France in 2003.

Doorenbos Group (also listed as *Symphoricarpos* × *doorenbosii* Krüssm.), are hybrids among *S. albus* var. *laevigatus*, *S. orbiculatus*, and *S. ×chenaultii*. Plants were raised by G.A. Doorenbos, The Hague, before 1940. 'Erect' is a vigorous, compact, upright form with rose-lilac fruits. 'Magic Berry' is a compact-spreading shrub with abundant rose-pink (rose-lilac) fruits; I saw this clone in Amsterdam and was impressed by the fruit display. 'Mother of Pearl' is vigorous, semi-pendulous, 5 to 6' high shrub with broad elliptic or obovate leaves and dense clusters of 1/2" wide, white, pink-cheeked fruits. 'Pink Magic', with pink-tinged flowers and polished, ivory-blushed-pink fruits, was listed by Heronswood; bears purplish pink fruits in great abundance along the length of the stems, fruits evident in October–November (November 4, 2006) and still present February 23, 2007; unfortunately, the leaves (fall) were smothered with mildew; what a disaster. 'White Hedge' grows 5' high, stiff and upright, and bears large, white fruits primarily in terminal clusters above the foliage. Their fruit effect justifies consideration for shady areas of the garden, but availability is limited in the United States. All should be hardy to –30°F and will probably prove adaptable to Zone 7. Cappiello reported that 'Mother of Pearl' was killed outright in Orono, ME. Newer cultivars have been introduced and I am not sure of affinity so will include them herein:

Amethyst™ ('Kordes')—Deep, vivid, purplish pink fruit; 3 to 5' high and wide plant; gray-green foliage; originated in Germany; Proven Winners® introduction; observed a fruiting plant on November 17, 2004 at the Raulston, the fruits almost white, a few pink touches here and there, certainly not as described under the original banner.

Bright Fantasy™ ('Bokrabright', PP 14,570)—Clear white fruits.

Charming Fantasy™ ('Kolcharm', PP 13,204)—Shell-pink fruits.

Magical Snowflake™ ('Kolmsno', PP 14,561)—Upright growth habit, freely branching; dark green leaves; good post-production longevity; primarily utilized for cut branches.

Magical Sweetheart™ ('Kolsweet', PP 13,206)—Habit similar to Magical Snowflake™; medium green leaves; large, light pink fruits; good post-production longevity.

Marleen® ('Ariso')—Rounded habit, 4' by 4'; pink flowers; large pink fruits in late summer; Pride of Place Plants introduction.

'Scarlet Pearl' (PP 13,244)—Deep pink fruits.

'Spun Sugar'—Gray-green leaves edged white; purple-red fruit in fall; Hines Nursery introduction.

Numerous Magical™ selections were named by Hans van Leyssen, Den Hout, Netherlands and assigned to the Kolster nursery. Counted 14 in one reference. All developed for the cut flower (branch) industry. Their everyday garden worthiness is unknown.

Symphoricarpos orbiculatus Moench — Indiancurrant Coralberry or Buckbrush
(sim-fō-ri-kār'pos ôr-bi-kū-lā'tus)

LEAVES: Opposite, simple, elliptic or ovate, 1/2 to 1 1/4" long, 1/4 to 3/4" wide, obtuse or acutish, rounded at base, dull dark green above, glaucous and pubescent beneath; petiole—1/12" long.

Symphoricarpos orbiculatus, Indiancurrant Coralberry or Buckbrush, grows 2 to 5' high by 4 to 8' wide and develops into a spreading, arching shrub. The foliage is a dull green (possibly blue-green) in summer and persists late in fall. I observed this species loaded with mildew growing next to *S. ×chenaultii* which had none. The flowers are yellowish white, flushed rose, borne in June or July,

in dense and short, axillary clusters and terminal spikes. The fruit is a purplish red, 1/6 to 1/4" diameter, berry-like drupe, maturing in October and persisting late into winter. 'Albovariegatus' ('Argenteovariegatus' and 'Taff's Silver Edge' all the same?) has rounded leaves with an irregular, white margin. 'Bowles Gold Variegated' has a wide, gold leaf margin. 'Central Avenue' bears brilliant burgundy fruits in fall. 'Hawkins' is a more compact form, 3' high, with dark green foliage tinted red in fall, coral red fruits. 'Leucocarpus' has white or whitish fruit. 'Variegatus' ('Foliis Variegatus') is a weak-growing, irregularly yellow-margined form, the leaves becoming creamy white-margined in full sun; I grew this for a number of years and was pleased with the performance; definitely more vigorous than given credit; now relegated to variegated plant heaven. New Jersey to Georgia, Kansas and Texas, west to South Dakota. Bonnie and I love southwest Virginia for scenery and literally bump into entire fields with *S. orbiculatus*. Almost a weed on the limestone soils. 1727. Zone 2 to 7(8).

Symplocos paniculata Miq. — Sapphireberry or Asiatic Sweetleaf

(sim-plō'kos pan-ik-ū-lā'ta)

FAMILY: Symplocaceae

LEAVES: Alternate, simple, elliptic or obovate to oblong-obovate, 1 1/2 to 3 1/2" long, 3/4 to 1 3/4" wide, acute or acuminate, broad-cuneate, finely serrate, dark green and glabrous above, conspicuously veined beneath and usually pubescent, rarely glabrous; petiole—1/8 to 1/3" long, hairy.

BUDS: Small, plump, broad-ovoid, imbricate, 1/16 to 1/8" long, gray-brown, sitting directly above raised, half-circle leaf scar.

STEM: Stout, grayish, glabrous or pubescent, vertical fissuring of epidermis; pith—brown, spongy.

BARK: On older plants develops gray flat ridges and darker fissures, becomes slightly stringy; reminds of the bark of *Lonicera maackii*.

SIZE: 10 to 20' high with a similar spread.

HARDINESS: Zone 4 to 8, has withstood -20 to -25°F and flowered normally.

HABIT: Large shrub or small, low-branched tree becoming wide-spreading at maturity; a particularly handsome specimen at the Arnold Arboretum was 20' high and 30' wide.

RATE: Slow.

TEXTURE: Medium.

BARK: Gray, ridged-and-furrowed, resembling that of *Lonicera maackii*.

LEAF COLOR: Dark green in summer; no appreciable fall color.

FLOWERS: Perfect or unisexual, 5-petaled, 30-stamened, filament white, anthers yellow, each flower about 1/2" diameter, creamy white, fragrant, flowers are borne in 2 to 3" long panicles in late May—early June on growth of previous season; full flower late April—early May, Chapel Hill, NC; the flower effect is much superior to honeysuckles.

FRUIT: Ellipsoidal, 1/3" long, one-seeded drupe that color-wise can be categorized as ultramarine, sapphire, bright turquoise-blue and lapis-lazuli blue, September-October and often stripped by the birds; the color is unique among fruiting shrubs; fruit production may fluctuate from plant to plant because of the nature of the flowers, some being perfect, others male or female; several shrubs should be planted to insure adequate cross-pollination and the best solution is to vegetatively propagate; individual plants are almost always self-incompatible.

CULTURE: Easily transplanted from a container or as a balled-and-burlapped specimen; light or heavy, well-drained soil is acceptable; pH 5 to 7; full sun to partial shade in South; best to prune during winter although some flower buds will be lost.

DISEASES AND INSECTS: None serious, have never seen a scratch on this shrub.

LANDSCAPE VALUE: Probably best used in the back of the shrub border, as an unpruned screen or as a small specimen tree; this is an excellent plant for attracting birds; specimens are long-lived and require essentially no maintenance; plant several seedlings or different clones to insure cross-pollination; had a lone plant in my Georgia garden that flowered well but set little fruit; another seedling is necessary for cross-pollination.

PROPAGATION: Softwood cuttings root readily and I have had 100% success with July cuttings, 1,000 ppm IBA-quick dip, peat:perlite, mist; cuttings should root in 6 to 8 weeks and should be hardened off in a cooler or cold frame, and transplanted when new growth occurs; over the years have successfully rooted this plant numerous times, yet have been unable to overwinter the cuttings. Seeds appear to be double dormant and require 3 to 4 months warm, followed by 3 months cold. In Mt. Airy, Cincinnati, OH, numerous stray seedlings are evident around several large shrubs.

ADDITIONAL NOTES: Certainly one of the handsomest of fruiting shrubs and should be used in every park, bird sanctuary and the like. A plant in full fruit is truly spectacular. See Dirr, "Sapphireberry has true blue fruit," *American Nurseryman* 150(12):42, 44, 46, 48 (1979). About 250 species (have seen references to 380 species) of evergreen and deciduous trees and shrubs primarily in warm temperate and tropical regions. *Symplocos tinctoria* is the only United States representative.

NATIVE HABITAT: Himalaya to China, Japan, Taiwan. Introduced 1875.

RELATED SPECIES:

***Symplocos tinctoria* (L.) L'Her.** — Horse-sugar
(sim-plō'kos tink-tō'ri-a)

LEAVES: Alternate, simple, elliptic to oblong-lanceolate, 3 to 6" long, half as wide, acute or acuminate, cuneate, entire or obscurely serrate, thickish, lustrous dark green above, paler and pubescent below, sweet taste is evident in old leaves.
STEM: Light gray-brown, pith chambered.

Symplocos tinctoria, Horse-sugar, is a semi-evergreen to deciduous shrub or small (15 to 25' high) tree that occurs in woods, swamps and bottomlands from Delaware to Florida and Texas. The national champion is 60' by 32' in southern Chesapeake, VA. The lustrous dark green leaves are attractive and to one degree or another may persist into spring. There were several colonies in the University's Botanical Garden that showed a distinct suckering tendency. The 1/3" diameter, cream-yellow, fragrant flowers occur in dense, axillary clusters on the previous season's growth during April–May before new leaves emerge. The fruits, which I have not seen on the Georgia plants, are orange or brown, 1/3 to 1/2" long, ellipsoidal drupes. Rather interesting native plant, probably best in a naturalized landscape. In Charleston, SC the plant grows in sandy soils as an understory component. The foliage is often lustrous dark green and certainly selections could be made for foliage, growth habit and possibly floral characteristics. See Weaver, *Arnoldia* 44:34–35 (1984) for a good overview. Grows in thin to dense woods, bluffs, sandy soils, stream borders, stable dunes. Plants in Charleston were evergreen; those in the Athens vicinity, with a few persistent leaves, largely deciduous. Witnessed in full flower in mid-March in sandy woods around Darian, GA. Cultivated 1780. Zone 7 to 9.

***Syringa meyeri* C.K. Schneid.** (in the trade often referred to as *S. palibiniana* Nak. or possibly *S. velutina* Komar.) — Meyer Lilac
(si-ring'ga mī'ēr-ī)

FAMILY: Oleaceae

LEAVES: Opposite, simple, 3/4 to 1 3/4" long, not quite as wide, elliptic-ovate to sometimes elliptic-obovate, acute or obtusish, entire, glabrous above, scarcely paler beneath and pubescent on the veins near base, with 2 to 3 pairs of veins from base nearly to apex, dark green, somewhat lustrous with a reddish purple rim around margin of young leaves; petiole—about 1/3" long.

SIZE: 4 to 8' high and 1 1/2 times that in spread.

HARDINESS: Zone 3 to 7; I have seen it growing at Callaway Gardens, Pine Mountain, GA.

HABIT: Small, dense, neat, broad-rounded, mounded shrub; excellent clean branch structure, one of the best lilacs for uniform, pristine outline in summer and winter.

RATE: Slow.

TEXTURE: Medium-fine in leaf; medium in winter.

LEAF COLOR: New leaves rimmed with a purplish margin, finally turning dark green; fall color is nonexistent.

FLOWERS: Violet-purple (I see pink in them but most of the botanical descriptions do not); each 1/2" long, 1/4" wide, flowers are densely packed in 4" long and 2 1/2" wide panicles, May, effective for 10 to 14 days, early April in Zone 7, fragrant but not the soft fragrance associated with Common Lilac; literally cover the entire plant and are spectacular; one of the best for flower effect if not adulterated by the vagaries of weather; flowers are formed on previous season's growth.

FRUIT: Capsule, warty, 1/2 to 3/4" long.

CULTURE: Does well in the Midwest and East, does not contract mildew like other species, requires little or no maintenance; possibly one of the easiest lilacs to grow, also suited to culture in the South; nifty study, *J. Environ. Hort.* 8(3):147–150 (1990), involving regeneration of 18 *Syringa* taxa by cutting all to 8" above ground, all regrew/regenerated at different rates, produced flowers and developed the typical form for each taxon; taxa included: *S. xchinensis*, Chinese Lilac; *S. xhenryi* C.K. Schneid., Henry Lilac; *S. xhyacinthiflora*, Early Flowering Lilac; *S. xjosiflexa*, Josiflexa Lilac; *S. josikaea*, Hungarian Lilac; *S. komarowii* C.K. Schneid., Komarof Lilac; *S. xlaciniata*, Feathered Persian Lilac; *S. meyeri*, Meyer Lilac; *S. microphylla*, Littleleaf Lilac; *S. xprestoniae*, Preston Lilac; *S. pubescens* Turcz., Hairy Lilac; *S. reflexa*, Nodding Lilac; *S. reticulata*, Japanese Tree Lilac; *S. reticulata* var. *mandschurica*, Amur Tree Lilac; *S. xskinneri* E. Skinner, Skinner Lilac; *S. sweginzowii*, Chengtu Lilac; *S. villosa*, Late Lilac; *S. vulgaris*, Common Lilac.

LANDSCAPE VALUE: Very handsome lilac, will start to flower when about one foot high; extremely floriferous; best used in shrub border with an evergreen background, flowers before leaves are fully developed; the flower buds emerge very early and can be injured by a late freeze.

CULTIVARS: Except for 'Palibin' the cultivars listed below are from the Fairytale® Series of compact lilacs bred by Neil Holland of Sheyenne Gardens, Hardwood, North Dakota and introduced by Bailey Nurseries; parentage is 'Palibin' × *S. pubescens* subsp. *microphylla* 'Superba'.

Fairy Dust® ('Baidust', PP 15,152)—Tawny pink buds open antique-pink, fragrant; compact habit, 4 to 6' by 4 to 6'; flowers about the same time as Tinkerbelle®.

'Palibin'—The compact form of the species that is prevalent in the trade; will grow 4 to 5' high, 5 to 7' wide; reddish purple buds open whitish pink, since there was significant confusion as to what constituted true *S. meyeri*, Dr. Peter Green, *Curtis's Botanical Magazine*, 183. Part III. New Series 116–120, provided a degree of order by providing the above name.

Prince Charming® ('Bailming', PP 15,349)—Rounded, 5 to 6' by 4 to 6'; wine red buds open to fragrant, single, lavender-pink flowers.

Sugar Plum Fairy® ('Bailsugar', PP 15,588)—Rounded, most compact in series, 4 to 5' by 4 to 5'; fragrant, single, rosy lilac flowers, will rebloom and has done so up to three times in a season.

Thumbelina® ('Baillina', PP 16,662)—Rounded, 5 to 6' by 5 to 6'; fragrant, medium pink buds open to single, light pink flowers, sweetest fragrance of the Fairytale® series.

Tinkerbelle® ('Balibelle', PP 12,294)—Upright 5 to 6' by 4 to 5'; wine red buds open to fragrant, single, pink flowers; small, dark green, mildew-resistant leaves.

PROPAGATION: Lilacs in general are not easy to root from cuttings and timing is critical; ideally softwood cuttings should be collected before end leaves mature, treat with 1,000 to 5,000 ppm IBA talc or quick dip, well-drained medium and mist; my successes with various *Syringa* species are minimal; Dirr and Heuser, 2006 offer a detailed discussion of the vagaries of lilac propagation. Seeds of most species should be provided 1 to 3 months cold, moist stratification.

ADDITIONAL NOTES: A good discussion of cultivated *Syringa* along with notes on introduction and identification was presented by Griffin and Maunder, *The Plantsman* 7(2): 90–113 (1985). Lilacs are overwhelming in sheer numbers, not necessarily quality attributes, and it is necessary to visit local gardens and survey the best. What grows in Boston, in all probability, has little opportunity for success in Atlanta. Also, Fiala's great reference on Lilacs by Timber Press is the best current reference. New reference in 2008, *Lilacs: A Gardener's Encyclopedia* by Fr. Fiala and Freek Vrugtman, Timber Press. If passionate, join the International Lilac Society, www.internationalilacsociety.org.

Worthwhile discussion by Jane Taylor, *The Plantsman* 11(4):225–240 (1990), of *Syringa* hybrids developed by Lemoine. Also includes Lemoine's contributions in *Philadelphus*, *Deutzia*, and *Weigela*. One of the great plant breeders of all time and the plants stand as testimonials to his understanding and manipulation of plant genetics.

NATIVE HABITAT: Hillier 2002 noted that the typical form is known only in cultivation but a wild variety from northern China was described. Northern China. Introduced 1908 and known only in cultivation.

RELATED SPECIES:

Syringa pubescens* subsp. *julianae (C.K. Schneid.) M.C. Chang & X.L. Chen, (formerly *S. julianae* C.K. Schneid.) (si-ring'ga pū-bes'en-z jū-lē-an-ā'ē), is a graceful, loose-arching shrub with oval, privet-like leaves, gray pubescent below. Pale lilac, fragrant flowers are borne in slender, upright panicles in May–June. My only introduction to the subspecies is 'Hers', essentially as described, which grew in the great garden of Dennis and Judy Mareb, Great Barrington, MA. This particular cultivar was loosely arching and totally un-lilac-like. In fact, I could not identify it. Typically 6 to 8' by 6 to 8'. 'Red Pixie' has dark reddish purple flowers that fade to pink; leaves resemble *S. meyeri*; branches do not weep like 'Hers'; considered a hybrid; seedling of 'Hers'; 4 to 6' by 4 to 6'. Species from central China. Zone 3 to 6. Introduced by E.H. Wilson about 1900.

Syringa pubescens* subsp. *microphylla (Diels) M.C. Chang & X.L. Chen (formerly *S. microphylla* Diels) — Littleleaf Lilac
(si-ring'ga pū-bes'enz mī-krō-fil'a)

LEAVES: Opposite, simple, orbicular-ovate to elliptic-ovate, 1/2 to 2" long, 1/3 to 1 1/4" wide, obtuse or abruptly acuminate, broad-cuneate to rounded at base, slightly pilose and medium green above, grayish green and pubescent beneath, at maturity only on the veins, ciliolate, or nearly glabrous; petiole—1/6 to 1/3" long; quite distinct from the previous and following species by virtue of leaf color and pubescence but often confused with those species.

Syringa pubescens subsp. *microphylla*, Littleleaf Lilac, is a very handsome, broad-spreading, dense shrub usually about 1 1/2 to 2 times as broad as tall, 6' by 9 to 12'. The medium green leaves are about one-half the size of those of *S. vulgaris*. Flowers are rosy lilac, fragrant, borne in 2 to 4" long, 1 1/2 to 2" wide panicles in May into early June and often flowering sporadically again in September. Makes a nice plant for the shrub border, in groupings, possibly a free-standing hedge. 'Superba' has single, deep pink (pink-red) flowers, grows twice as broad as tall and is quite floriferous. Another versatile, adaptable, heat tolerant, mildew resistant species that is worthy of consideration. Native to northern and western China. Introduced 1910. Zone 4 to 7(8).

Syringa pubescens* subsp. *patula (Palib.) M.C. Chang & X.L. Chen — Manchurian Lilac (previously *S. patula* (Palib.) Nak. and *S. velutina* Komar.)
(si-ring'ga pū-bes'enz pat'ū-la)

LEAVES: Opposite, simple, elliptic to ovate-oblong, larger than those of *S. meyeri* or *S. pubescens* subsp. *microphylla*, 2 to 5" long, 1/2 to 2" wide, acuminate, broad-cuneate or rounded at base, entire, dull dark green and slightly pubescent to glabrous above, densely pubescent beneath or pilose only on midrib or veins, leaf with undulating (wavy) margins and surface; petiole—1/4 to 1/2" long.

STEM: Purplish young shoots, slightly downy or glabrous at maturity.

Syringa pubescens subsp. *patula*, Manchurian Lilac, is frequently confused with *S. meyeri* and *S. pubescens* subsp. *microphylla* but is a more upright, vigorous (9') shrub. Panicles often in pairs from the terminal pair of buds of the previous season's shoots, each 4 to 6" long and rather thinly set with lilac-purple flowers of pleasing fragrance in May–June. 'Miss Kim' was once listed as growing 3' high and 3' wide with 3" long panicles of purple buds which open to fragrant icy blue flowers. I have seen this clone growing in the Holden Arboretum and, at that time, it was 6' high and 4 to 5' wide. I saw the parent plant at the Horticultural Farm at the University of New Hampshire and it was about 8 to 10' high and oval-rounded. It may develop a reasonably good reddish purple fall color. 'Miss Kim', touted as heat tolerant, will grow and flower in Zone 7 but is tatty by late summer–early fall, particularly the foliage. Have grown this cultivar in the Georgia trials and our Chapel Hill garden. Lovely in flower, about late April–early May (Athens), a degree disheveled later. 'Josee' offers lavender-pink, repeat flowers on a compact 4 to 6' by 4 to 6' shrub; hybrid origin. 'Karen' produces fragrant, single, pink flowers that mature white; habit upright like 'Miss Kim'; leaves rounded like *S. meyeri*; compact, 5' by 4'; Father Fiala introduction. Miss Susie™ ('KLMone') is a pink-flowering form of 'Miss Kim', 6 to 8' by 6 to 8', with burgundy fall color, introduced by Roy Klehm. The so called *Syringa palibiniana* Nak. as used in the nursery trade does not really exist. One is buying either *S. meyeri* or *S. pubescens* subsp. *patula* or, perhaps, subsp. *microphylla*. Have seen subsp. *patula* at Callaway Gardens, Pine Mountain, GA, doing reasonably well. Northern China, Korea. Cultivated 1902. Zone 4 to 7(8).

Syringa reticulata (Bl.) Hara (formerly *S. amurensis* Rupr. var. *japonica* (Maxim.) Franch. & Savat.) — Japanese Tree Lilac
(si-ring'ga re-tik-ū-lā'ta)

LEAVES: Opposite, simple, entire, broad-ovate to ovate, 2 to 5 1/2" long, about half as wide, acuminate, rounded or subcordate, dark green above, grayish green and reticulate beneath and glabrous or slightly pubescent; petiole—1/2 to 1" long.

BUDS: Sessile, subglobose, with 4 pairs of scales, end bud frequently absent, brownish.
STEM: Stout, shiny brown, heavily lenticelled resembling cherry bark, glabrous.

SIZE: 20 to 30' in height; 15 to 25' in spread.

HARDINESS: Zone 3 to 7, have not observed a plant in Zone 8.

HABIT: Large shrub or small tree with stiff, spreading branches developing a somewhat oval to rounded crown; with time branches and leaves become somewhat arching, the entire tree much more graceful.

RATE: Medium, 9 to 12' over a 6 to 8 year period.

TEXTURE: Medium in all seasons.

BARK: Cherry-like, reddish brown to brownish on young and old stems, marked with prominent horizontal lenticels, good feature to separate it from other lilacs; on old trunks gray, scaly.

LEAF COLOR: Dark green in summer; like most lilacs minimal fall color; leaves out early, often by late March in Zone 7; leaves about 1/3 full size, March 21, 2009 at Milliken Arboretum.

FLOWERS: Perfect, creamy white, fragrant, early to mid-June, effective for 2 weeks, borne in large terminal 6 to 12" long and 6 to 10" wide panicles, extremely showy in flower, odor somewhat akin to that of privet, petals turn brown with age and appear rather untidy toward the end of their tenure; a long pole pruner does wonders for the tree's appearance.

FRUIT: Warty, glabrous, scimitar-shaped, dehiscent, 3/4" long capsule, blunt at apex.

CULTURE: This discussion applies to the lilac species in general; transplant balled-and-burlapped or from a container, actually lilacs are easy to move; soil should be loose, well-drained and slightly acid although lilacs are pH adaptable; quite adaptable to limestone (high pH) soils; full sun for best flowering; pruning should be accomplished after flowering or if a plant is overgrown (applies to multi-stemmed clones) cut it to the ground for complete rejuvenation; should be good air movement; prefer cool summers.

DISEASES AND INSECTS: Bacterial blight, *Phytophthora* blight, leaf blights, leaf spots, powdery mildew (bad on Common Lilac, Persian Lilac), wilt, other minor pathological problems, ring spot virus, witches' broom, frost injury (in late spring the young leaves may be injured by near freezing temperatures), graft blight (occurs on lilacs grafted on privet), leaf roll necrosis (caused by various air pollutants), lilac borer, leopard moth borer, caterpillars, giant hornet, lilac leaf miner, scales and several other insects of negligible importance; it should be evident that lilacs require a certain degree of maintenance; I have seen the borer and scale insects decimate large shrubs and entire plantings.

LANDSCAPE VALUE: Possibly the most trouble-free lilac; excellent specimen tree, street tree, good in groups or near large buildings; one of my favorite lilacs; I believe there is a continued need for selection of superior flowering and foliage types within the species; have seen the species performing magnificently on the Nebraska campus at Lincoln as well as in Burlington, VT and throughout New England; I consider it the toughest of the lilacs but the flower fragrance is somewhat privet-like which turns many people off; is resistant to mildew, scale and borer, which is an unbridled recommendation; in the South, Zone 7 and higher, leaves emerge early and often desiccate or become necrotic by mid to late summer, not a good doer in the heat of a southern summer.

CULTIVARS:

subsp. *amurensis* (Rupr.) P.S. Green & M.C. Chang supersedes var. *mandschurica* (Maxim.) Hara.—The habit, shrubby, 6 to 8'(12') high; leaves smaller, more refined, taper-pointed than species; producing white flowers in May–June; develops peeling-exfoliating bark; northeast China, Siberia, Korea; introduced 1855.

'Chantilly Lace'—Margins on young leaves pale yellow, maturing to creamy yellow, margin width varying from 1/5 to 4/5", central portion of leaf blotched dark green with light green halo, leaves may burn in hot sunny locations; Introduced by Herrmann Nursery, Limehouse, Ontario.

'China Gold'—Described as more upright and narrow in habit than typical; young shoots reddish, young leaves light golden, turning pale yellow-green in summer; flower buds and open flowers more cream than pure white; 25-year-old parent tree was 25' high; Zone (3)4; from the late Father Fiala, Falconskeape Gardens, Medina, OH; raised from colchicine-treated seed in 1955, first flowered in 1986, see *HortScience* 26:476–477 (1991).

'Golden Eclipse' (PP 15,990)—Upright, compact selection, 18 to 24' by 8 to 14'; emerging leaves green with darker green center, margin eventually turns gold; field tested at Bailey's in Minnesota where foliage color was held in full sun; cream-white flowers in June; Bakker Nursery, Ontario, Canada introduction.

'Ivory Silk'—A 1973 selection by Sheridan Nursery, Ontario, Canada, that flowers at a young age and is a rather sturdy and compact, oval-rounded, dense form; deep green leaves; heavy-flowering; 20 to 25' by 15'; has been in commerce for about 35 years and still one of the best forms; ivory-white flowers fully expressed May 16, 2004 at the Raulston Arboretum.

'Regent'—An exceptionally vigorous upright form; Princeton Nursery introduction; utilized in Spartanburg, SC and it cooked in the heat.

Signature™ ('Sigzam')—Rounded panicles, flowers 1 to 2 weeks later than 'Ivory Silk'; inflorescences are smaller; oval habit, more compact than 'Ivory Silk'; Lake County Nursery introduction.

Snow Cap™ ('Elliott')—More compact than 'Ivory Silk', 15 to 20' high, 10 to 12' wide; dark green leaves; abundant flowers; Carlton Plants introduction.

Snow Dance™ ('Bailnce', PPAF)—Graceful, vase-shaped, spreading habit; dark green leaves; annual and abundant, fragrant white flowers in June (Minnesota); sterile and produces no fruits; 18' by 20'; selected by Rod Bailey, offered under First Editions™ brand by Bailey Nurseries.

'Summer Snow'—Offers compact rounded crown, profuse large panicles of fragrant, creamy white flowers, handsome glossy cherry-like bark; good small street or lawn tree, 20' high, 15' wide; a Schichtel Nursery introduction.

PROPAGATION: Seed dormancy is variable but cold stratification for 30 to 90 days at 34 to 41°F is recommended; I have attempted to grow this lilac from seed; however, all attempts met with failure; the seed, in all cases, was purchased and the origin was unknown. Cuttings which I collected in June rooted 90% when treated with 10,000 ppm (1%) IBA/50% alcohol and placed in sand under mist. Root formation was extremely profuse. Work in Canada indicated that early July, 8 to 10" long cuttings rooted 87% after treatment with 8,000 ppm IBA.

NATIVE HABITAT: Northern Japan. Introduced 1878.

RELATED SPECIES:

Syringa reticulata* subsp. *pekinensis (Rupr.) P.S. Green & M.C. Chang (formerly *Syringa pekinensis* Rupr.) — Pekin Lilac

(si-ring'ga re-tik-ū-lā'ta pē-kin-en'sis)

LEAVES: Opposite, simple, ovate to ovate-lanceolate, 2 to 4" long, 1 to 2" wide, acuminate, cuneate, dark green above, grayish green beneath and scarcely veined, quite glabrous; petiole—1/2 to 1" long.

Syringa reticulata subsp. *pekinensis*, Pekin Lilac, is somewhat similar to the above but smaller (15 to 20'), although not absolute as I have observed 30' high plants, with a more informal (multi-stemmed) habit and finer texture throughout. With only an exception or two, plants I've observed were multi-stemmed, upright arching, loose and open. Have seen good tree forms at Coker, Minnesota, Raulston, and Arnold Arboreta. The leaves and stems are smaller and finer. The flowers are yellowish white (creamy) and appear before *S. reticulata* in 3 to 6" long (often 2x this) panicles. Full flower, late June, at the Minnesota Landscape Arboretum. I have seen plantings in various arboreta where the two plant types were flowering at about the same time. The bark is often quite handsome and adds significantly to the plant's landscape assets. Bark may be similar to *S. reticulata* or on some trees exfoliate in rich brown flakes or sheets. I continue to witness new introductions with China Snow® ('Morton') the best because of the papery, exfoliating bark reminding of the best *Prunus serrula* bark. Also, large specimens at the Coker and Raulston Arboreta, Triangle area, NC point to increased heat tolerance over *S. reticulata*. Cultivars include: Beijing Gold® ('Zhang Zhiming') grows 20' by 20', produces yellowish flowers in June, vigorous, upright-spreading with arching branches, early leafing at Milliken Arboretum, March 21, 2009, same stage, about 1/3 full size, as China Snow®; China Snow® ('Morton') develops an upright, spreading outline, 20' by 20', dark green summer foliage, yellowish in fall, cream-white flowers and outstanding amber-cherry-red exfoliating bark, this appears the best of the lot, early leafing at Milliken Arboretum, March 21, 2009. In the last edition this was listed as Water Tower® ('Morton'). The name change reflects commercial expediency. Witnessed a great specimen in late October at the Chicago Botanic Garden with the bark as described herein. Copper Curls™ ('SunDak', PP 16,570) forms a rounded canopy with cream-white flowers, 12 to 14 days after *S. vulgaris*; summer foliage is shiny mid green; the bark peels, curls, flakes in coppery-orange colors; introduced by Dr. Dale Herman, NDSU. 'Pendula' has graceful, arching (drooping) branches. Select trees fall into this category. Summer Charm® ('DTR124', PP 8,951) is upright-spreading, 20' by 15', with lustrous dark green leaves, cream-white panicles, overall finer texture than *S. reticulata*, bark exfoliating in amber curls not to the degree of China Snow® but still effective; introduced by the late Bill Wandell. 'Yellow Fragrance' is listed in RHS Plant Finder 2008–2009 and various European references but without a technical description. Northern China. Introduced 1881. Zone 4 to 7.

Syringa villosa Vahl — Late Lilac

(si-ring'ga vil-lō'sa)

LEAVES: Opposite, simple, broad-elliptic to oblong, 2 to 6" long, 1 to 2 1/2" wide, entire, acute at ends, dull dark green above, glaucescent beneath and usually pubescent near the midrib, rarely glabrous, veins impressed creating a pleated appearance; petiole—1/4 to 1 1/4" long.

SIZE: 6 to 10' high and 4 to 10' wide.

HARDINESS: Zone 3 to 7; have not observed in Zone 7.

HABIT: Bushy shrub of dense rounded habit with erect or ascending, stout, stiff branches.

RATE: Slow to medium.

TEXTURE: Medium in leaf and winter.

LEAF COLOR: Medium to dull dark green in summer.

FLOWERS: Rosy lilac to white, not as fragrant as *S. vulgaris*, with a curious odor similar to privet; mid to late May possibly into early June; borne in dense, pyramidal, 4 to 8" long panicles, forms a true terminal bud and 3 panicles often occur at the end of the shoot, flowers are borne on the current season's growth flush rather than last season's wood like *S. vulgaris*.

FRUIT: Capsule, 1/2" long.

CULTURE: See under *S. reticulata*.

DISEASES AND INSECTS: See under *S. reticulata*.

LANDSCAPE VALUE: Nice lilac for the shrub border; performed well in Midwest and East, seldom used in contemporary gardens.

NATIVE HABITAT: China. Introduced 1882.

CULTIVARS: The Preston Lilacs (*Syringa* × *prestoniae* McKelv.) are the result of crosses between *S. villosa* and *S. komarowii* subsp. *reflexa*. Additional species were utilized. They are extremely hardy (Zone 3) and possess many of the morphological features of *S. villosa*. Developed by Isabella Preston of Ottawa in 1920's and later. Cultivars continue to be developed; however, somewhere along the line there needs to be a stopping point for the glut becomes mind-boggling. Krüssmann listed 43 cultivars.

'Alexander's Pink'—Large, pink flowers; later than *S. vulgaris*; 6 to 9'.

'Agnes Smith'—Single, white, fragrant flowers; 6 to 8' by 6 to 8'; bred by Dr. Owen Rogers, University of New Hampshire.

'Audrey'—Light magenta-pink outside, almost white within, in 9" long, dense, conical panicles.

'Bellicent'—Pink

'Coral'—Single, light pink flowers, considered best pink; compact habit.

'Desdemona'—Single, purplish flowers.

'Donald Wyman'—Deepest pink to almost reddish flowers with buds and flowers the same color, 6" by 4" panicles, opening after *S. vulgaris* types; 8 to 10'; among the best of the Prestons.

'Elinor'—Dark purplish red in bud, opening to pale lavender, panicles erect.

'Guinevere'—Purple

'Hiawatha'—Single, red-purple opens to pink, good mildew resistance and foliage.

'Isabella'—Single, pinkish lilac flowers in large (1' long, 8" wide), pyramidal panicles.

'James MacFarlane'—Single, bright pink, light fragrance, June; vigorous, 8 to 10' high; one of the more common commercial forms; introduced by University of New Hampshire.

'Jessica'—Single violet flowers, 7" long, 5" wide panicles.

'Juliet'—Lilac-pink flowers.

'Kim'—Lavender-purple flowers, large panicles.

'Lynette'—Pink

'Minuet'—Light purple buds, light lavender flowers; large, dark green leaves; 6 to 8' high, composite of *S. josikaea*, subsp. *reflexa*, and *S. villosa*.

'Miss Canada'—Deep reddish buds, bright rose-pink flowers; vigorous grower; late-flowering; 6 to 8' high.

'Nocturne'—Deep violet purple, opening to lilac pink; good mildew resistant foliage; approximately 6' high.

'Patience'—Single lilac flowers.

'Redwine'—Single magenta flowers, considered darkest red form, probably more deep red in bud, opening pink, slight fragrance, late-flowering; 8 to 10'.

'Royalty'—Violet-purple flowers; handsome deep green foliage; 8 to 10'.

'Virgilia'—Deep lilac magenta in bud, opening pale lilac; compact habit.

'W.T. Macoun'—Lilac pink, large panicles.

PROPAGATION: See *S. meyeri*.

RELATED SPECIES:

Syringa emodi Wall. ex D. Don — Himalayan Lilac
(si-ring'ga ē-mō'dē)

Syringa emodi, Himalayan Lilac, is a large shrub with 4 to 8" long, dark green leaves, pale below; flowers pale lilac in bud, opening white, off fragrance, June. 'Aurea' has soft yellow leaves, best out of hot sun. While 'Elegantissima' ('Aureovariegata') bears large cream-yellow margined leaves with an irregular green-spotted center; striking in May–June, diminishing thereafter. Western Himalaya. Introduced 1838. Zone 6.

Syringa josikaea Jacq. f. ex Rchb. — Hungarian Lilac
(si-ring'ga jos-ik'ē-a)

LEAVES: Opposite, simple, broad-elliptic to elliptic oblong, 2 to 5" long, acute to acuminate, broad cuneate to rounded, ciliolate, entire, lustrous dark green above, glaucescent (whitish) below, sparingly hairy on veins or glabrous; petiole—about 1/3" long.

Syringa josikaea, Hungarian Lilac, is a 8 to 10' high, 8 to 12' wide, spreading, arching, multi-stemmed shrub that offers slightly fragrant, lilac-violet flowers in 4 to 7"(8") long, narrow panicles from late May into June. The leaves, habit and flowers remind of *S. villosa* but the color is usually deeper at least on plants I have seen. The loose panicles are handsome for late season effect. Has been used as a parent in the development of many late-flowering hybrids. Several selections including: 'Emerald' a medium-sized, compact shrub, 5 to 7' high, bright emerald green foliage, abundant dark lilac-pink flowers; 'Eximia' with light red to pink flowers; 'H. Zabel' with red fading to white flowers; 'Pallida' with pale violet flowers; 'Rosea' with pink flowers; and 'Rubra' with violet, red-tinted flowers. Central and eastern Europe. Introduced about 1830. Zone 5 to 7.

Syringa komarowii C.K. Schneid. subsp. ***reflexa*** (C.K. Schneid.) P.S. Green & M.C. Chang (formerly *S. reflexa* C.K. Schneid.) — Nodding Lilac
(si-ring'ga kō-ma-rō'ē-ī rē-flek'sa)

LEAVES: Opposite, simple, oval-oblong to oblong-lanceolate, 3 to 6"(8") long, half as wide, acuminate, cuneate, entire, dark green and glabrous above, villous on veins beneath and paler; petiole—1/2" long.

Syringa komarowii subsp. *reflexa*, Nodding Lilac, is a large 10 to 12' high and wide, stout-stemmed shrub with handsome foliage and 6 to 10" long, 1 1/2 to 4" wide, cylindrical or narrowly pyramidal panicles of purplish pink flowers that age pink with a white interior. Flowers are packed in a series of whorls along the length of the terminal, leafy, arching to pendulous panicle. I cannot pick up any fragrance of consequence. A parent of *S. ×prestoniae* and other late-flowering hybrids. For the lilac collector a worthwhile addition; for the gardener with space for one lilac, forget it. Central China. Introduced 1904 by E.H. Wilson. Zone 5 to 7.

Syringa sweginzowii Koehne & Lingl. — Chengtu Lilac
(si-ring'ga sweg-in-zō'ē-ī)

LEAVES: Opposite, simple, oblong or ovate, 2 to 4" long, 1 to 2" wide, abruptly acuminate, broad-cuneate to rounded, thinnish, entire, dark green and glabrous above, light green below and pilose pubescent on veins; petiole—1/4 to 1/2" long.

Syringa sweginzowii, Chengtu Lilac, is another of the late-flowering species that offers 6 to 8" long, fragrant panicles of rosy lilac, fading to flesh pink. The panicles occur at the end of the shoot with a few lateral ones developing further down the stem. The inflorescence is extremely loose and the flowers tend to hang and do not always present themselves in the most aesthetic manner. The habit is elegantly upright with landscape size approximately 10 to 12' by 10 to 12'. With subsp. *reflexa*, it resulted in the hybrid, ***Syringa ×swegiflexa*** Hesse. 'Fountain' produces nodding pale pink panicles in June. Northwestern China. Introduced 1914. Zone 5 to 6.

ADDITIONAL NOTES: Despite the lack of overwhelming fragrance, this group of lilacs deserves landscape consideration because of lateness and quantity of flowers. All are quickly recognizable by the impressed veins, rather loose inflorescences, late flowers, and inflorescences that appear at the terminus on the new growth of the season. All can be separated from each other by floral characteristics which, for example, come down to anthers not protruding from the corolla in *S. sweginzowii*, while those of *S. villosa* do. ***Syringa wolfii*** C.K. Schneid., Manchurian Lilac, is also included here as it is later than *S. vulgaris* with lavender flowers in up to 12" long panicles, on a large >10' high shrub, possibly more heat tolerant than *S. vulgaris* types. Northeast China, Korea. Cultivated 1910. Zone 4 to 7.

Syringa vulgaris L. — Common Lilac

(si-ring'ga vul-gā'ris)

LEAVES: Opposite, simple, ovate or broad-ovate, 2 to 5" long, 3/4's to as wide, acuminate, truncate or subcordate to broad-cuneate, entire, dark green almost bluish green, glabrous; petiole—3/4 to 1 1/4" long.

BUDS: Usually at end of stem, referred to by author as double terminal buds, 1/4 to 1/3" long, ovoid, plump, somewhat 4-sided, imbricate with 3 to 4 pairs of reddish brown scales; vegetative—smaller, 1/16 to 1/8" long, reddish brown, perhaps with only 2 pairs of visible scales.

STEM: Stout, angled, appearing 4-sided on first year stems, lustrous brown, glabrous, small raised lenticels, leaf scars raised, crescent-shaped; pith—solid, white.

SIZE: 8 to 15' in height (to 20') with a spread of 6 to 12'(15').

HARDINESS: Zone 3 to 7.

HABIT: Upright leggy shrub of irregular outline but usually devoid of lower branches after a time and forming a cloud-like head of foliage; suckers, forming rather imposing thickets; visited McLaughlin Garden, Paris, ME in October 2006 and was somewhat overwhelmed by the Houdini-like escapism of the species as the 'collection' of Common Lilac had meshed into a continuum of large and small stems/trunks, virtually monoculturing parts of the garden.

RATE: Medium.

TEXTURE: Medium to coarse in leaf depending on age and size of plant; coarse in winter.

FLOWERS: Lilac, extremely fragrant, early to mid-May (early April, Athens); borne in 4 to 8" long panicles, usually in pairs from the terminal buds; late-April at Swarthmore College; mid-May in Boston, Lilac Sunday is the great celebration of Syringaism at the Arnold Arboretum.

FRUIT: Smooth, 5/8" long, beaked dehiscent capsule.

CULTURE: Best soil is one close to neutral and supplemented with peat or leaf mold; old flowers should be cut off as soon as flowers fade; I am continually astonished at the resiliency of the species and its cultivars as I travel throughout the Midwest and particularly Northeast; in cities, towns, farmsteads, old abandoned homes, the lilac resides, seemingly oblivious to the transgressions of mankind.

DISEASES AND INSECTS: Unfortunately, many; see *S. reticulata*.

LANDSCAPE VALUE: Flowers of only value, probably best reserved for the shrub border or in groupings; considerable nostalgia attached to this shrub, often associated with Grandmother or Mom; my Mom would always pick large bouquets for the house and the fragrance literally permeated every room; I have tried to convince myself to plant one but in Zone 7 to 8 the plant is not prosperous, lacks vigor and does not flower reliably from year to year; breeders have a golden (lilac) opportunity if heat tolerance, low chill, could be integrated along with superb fragrance and myriad colors.

CULTIVARS: There are numerous clones (a 1990 publication, *American Horticulturist* 69(4):34–38, said 2,000 clones). Donald Wyman has a valuable list in his *Shrubs and Vines for American Gardens* based on observations of the lilac collection at the Arnold Arboretum. Also Krüssmann, *Manual of Cultivated Broadleaved Trees and Shrubs III* and Bean present extensive lists of cultivars. A Timber Press (2002) book on lilacs by Father Fiala, *Lilacs: The Genus Syringa*, is another worthy reference. Revision, 2008, by Fiala and Vrugtman is excellent. Noted that Lemoine Nursery, Nancy, France hybridized and introduced over 200 lilacs in late 19th through first half of 20th century. An interesting historical perspective is provided by Torer, *Horticulture* 61(5):25 (1983). My treatment is gleaned from many sources including: Rogers, *American Horticulturist* 57(2):13–17 (1978). This list resulted from a survey conducted by Mr. Frank Niedz in 1970 to determine the most popular types. Also, John H. Alexander, III, and the Arnold Arboretum permitted me to use a list of lilacs, "Fifty of the best lilacs for the gardens of New England", that appeared in *Arnoldia* 49(2):2–7 (1989). Hillier, 2002, presents single and double selections, about 52 in total. RHS Plant Finder 2008–2009 lists only 37 cultivars.

'Aino'—Single, fragrant, violet-blue, 4/5 to 1" diameter, in 8 to 10" long panicles; foliage dark green, disease resistant; 7 to 10' high, moderate suckering; *HortScience* 26(5):476 (1991).

'Alvin R. Grant'—Single, red-purple in bud, opening purple; *HortScience* 31(3):327–328 (1996).

'Aucubaefolia'—Double blue flowers; gold and green leaves.

'Bernard Slavin'—Flowers single with some radial doubling, buds grayed yellow opening to white, fragrant; *HortScience* 32(4):587–588 (1997).

'Bishop McQuaid'—Flowers single with radial doubling, buds purple-violet opening to purple-violet, very fragrant; *HortScience* 32(4):587–588 (1997).

'Bridal Memories'—Shrub of globose habit, dense foliage, single, creamy white, cup-shaped, 3/4" diameter flowers, flowers heavily in alternate years, lightly in off years; *HortScience* 29(9):972 (1994).

- 'Clyde Heard'—Single, medium red-purple in bud, purple when open, fading to pale red-purple.
 'Comtesse d'Harcourt'—Single, pure white, *HortScience* 31(3):327–328 (1996).
 'Elsa Maasik'—Single, fragrant, deeper purple, 3/4 to 7/8" wide, in 6" long panicles; dark green, disease resistant foliage; 7' high shrub, moderate suckering; grown from open-pollinated seed of 'Ludwig Spaeth', *HortScience* 26(5):476 (1991).
 'Frederick Douglass'—Flowers single with radial doubling, buds purple-violet opening to blue-violet, fragrant; *HortScience* 32(4):587–588 (1997).
 'Independence'—Flowers single, buds gray-orange opening to yellow-white, slightly fragrant; *HortScience* 32(4):587–588 (1997).
 'Martha Stewart'—Single, purple in bud, opening violet-blue; *HortScience* 31(3):327–328 (1996).
 'McMaster Centennial'—A large, vigorous shrub, white double flowers; hybrid of 'Primrose' and 'St. Joan'.
 'New Patriot Variegated-Lilac' (PP 17,110)—Cream-white variegation covers 10 to 100% of leaves on upper and lower surfaces; variegation subsides as leaves mature; flowers are light violet-blue; grows 8 to 10' by 4 to 6'; slow growing; discovered in 1985 in an old farmstead in Mitchell, SD by Jimmy Krsnak.
 'Prairie Petite'—Light pink, fades to lavender, parent plant was 3.25' by 3.8' after 25 years; *HortScience* 31(1):166 (1996).
 'Prince Wolkonsky'—Double, red-purple in bud, pink-lilac when open; *HortScience* 31(3):327–328 (1996).
 'Princesse Sturdza'—Single, dark pink in bud, pink-lilac when open; *HortScience* 31(3):327–328 (1996).
 'Silver King'—Single, silver-lavender flowers; listed in Briggs 2008–2009 catalog.
 'Tiiana'—Single, pink, fragrant, 4/5" wide, in up to 14" long, 4" wide panicles; dark green, disease resistant foliage; 10' high shrub, suckering moderately; *HortScience* 26(5):476 (1991).

MR. FRANK NIEDZ'S LIST

Color	Double	Single
White	'Casmier Pierre' (2007) 'Ellen Willmott' 'Edith Cavell' 'Mme. Lemoine' (vigorous)	'Aloise' 'Florence Stepman' 'Jan Van Tol' (fairly resistant to mildew) 'Marie Fincar' (2007) 'Mont Blanc' 'Rochester' (slow-growing) 'Slatter's Elegance' (2007) 'Vestale'
Violet	'Maréchal Lannes' 'Violetta'	'Cavour' 'De Miribel'
Blue	'Ami Schott' 'Nadezhda' 'Olivier De Serres' 'Prés. Grévy'	'Decaisne' 'Firmament' 'President Lincoln'
Lilac	'Alphonse Lavallée' 'Henri Martin' 'Léon Gambetta' 'Victor Lemoine'	'Christophe Columb' 'Jacques Callott'
Pink	'Belle De Nancy' 'Edward J. Gardner' 'Fantasy' 'Katherine Havemeyer' (mildew resistant, good season-long foliage) 'Mme. Antoine Buchner' 'Montaigne' 'William Robinson'	'Lucie Baltet' 'Macrostachya' 'Maiden's Blush'
Magenta	'Charles Joly' (fairly resistant to mildew, good foliage) 'Paul Thirion' 'Prés. Poincaire'	'Capitaine Baltet' 'Clyde Heard' 'Congo' 'Mme F. Morel'
Purple	'Adelaide Dunbar' (fairly resistant to mildew, good foliage) 'Paul Hariot'	'Agincourt Beauty' (2007) 'Hulda' 'Ludwig Spaeth' 'Night' 'Monge' 'Mrs. W.E. Marshall'

+ indicates a high degree of fragrance

* indicates an early-blooming hybrid

TEN FAVORITE UNCOMMON LILACS (from Alexander's Article)

The "best fifty" list includes only cultivars of *Syringa vulgaris* and the early-flowering *S. xhyacinthiflora* because they have the general appearance of the traditional or common lilac. Hybrids and selections of the species listed below have leaves, flowers and fragrance that are different, and offer adventurous gardeners the opportunity to break with tradition.

Syringa xlaciniata

S. meyeri

S. meyeri 'Palibin'

S. pekinensis

S. xprestoniae 'Agnes Smith'

S. xprestoniae 'Miss Canada'

S. pubescens

S. pubescens subsp. *microphylla* 'Superba'

S. pubescens subsp. *patula* 'Miss Kim'

S. reticulata

HEAT TOLERANT, LOW CHILL CULTIVARS

The Descanso hybrids were developed in Southern California for good flower production in mild winter environments. To my knowledge, none has proven well-adapted to lower Zone 7 and 8 in the Southeast.

'Angel White'—Single white flowers in generous quantities; described as flowering well in warm climates.

'Blue Boy'—Blue flowers.

Blue Skies® ('Monore', PP 6,877)—Lavender-blue, single flowers; dark blue-green leaves; 8 to 10' high; low winter chill; not absolutely sure about Descanso origin.

'California Rose'—Single, clear pink flowers, early flowering.

'Chiffon'—Lavender flowers.

'Dark Knight'—Single purple flowers, minimal chill requirements so should be suitable for warmer climates.

'Forrest Kresser Smith' ('Mrs. Forrest K. Smith')—Single lavender flowers; selected for low winter chill requirements.

'Lavender Lady'—Lavender-purple, single, fragrant flowers; open growth habit; result of cross between *S. vulgaris* × *S. xlaciniata*; heat tolerance imparted by the latter parent.

'Sylvan Beauty'—Rose-lavender flowers.

FATHER FIALA'S LILACS

The following cultivars were selected for color, size, form, fragrance, habit of growth and disease resistance.

Please see Fiala's *Lilacs: The Genus Syringa*, Timber Press, 2002 and 2008, for additional details.

White

'Avalanche'—Large white, single flowers, fine lingering fragrance; rounded to upright habit, about 9' high; *S. vulgaris* type, 'Flora' × 'Carley'.

'Fiala's Remembrance' ('Father John Fiala', 'Father John', 'Fiala Remembrance')—Yellow in bud, cream-white when open, double, large petals; 8' to 10' by 8' to 10'; named in memoriam for Father Fiala who produced a modern generation of lilacs.

Bicolor

'Albert F. Holden'—Deep violet, single flowers with a silvery blush on the reverse of the petals, good fragrance, large loose-open, somewhat reflexed panicles; dark green foliage, mildew resistant; moderately rounded 8 to 10' by 10'; *S. vulgaris* type.

Blue

'Blanche Sweet'—Ethyl blue buds open to whitish blue petals tinged with pink, fine fragrance; good foliage; upright to 10'; a *S. xhyacinthiflora* selection, mentioned under *S. xhyacinthiflora* also.

'Little Boy Blue' ('Wonder Blue', 'Wonderblue' in *HortScience* 24(3):435 (1988))—Sky blue flowers of good fragrance on a compact rounded 4 to 5' high shrub; dark green foliage; *S. vulgaris* type.

'Wedgewood Blue'—Lilac-pink buds open to the blue background of English Wedgewood pottery, excellent fragrance, large somewhat wisteria-like panicles; excellent mildew resistance; lower growing to 6' high 6 to 8' wide; *S. vulgaris* type.

Pink

'Atheline Wilbur'—Deep rose-lavender buds open to double, orchid, rose and violet flowers; 7 to 10' by 7 to 10'; *S. vulgaris* type.

'Edward J. Gardner'—Dark rose-pink buds open to double pink flowers, colors softening as the flower ages.

'Lark Song'—Large, single, pink flowers and minimal fruits, extremely floriferous; 8 to 10' by 6 to 8'.

'Letha E. House'—Single, pale lilac with hint of rose-pink, curved petals with light lavender-pink undersides, very fragrant; 8 to 10' by 8 to 10'; *S. vulgaris* type.

'Marie Francis'—True pink, almost 'Shrimp Pink', single, very fragrant; smallish in habit to 5' high, 5' wide; *S. vulgaris* type.

Magenta and Purple

'Arch McKean'—Bright reddish purple, individual flowers, 4/5 to 1 1/5" wide, in large upright panicles, heavy-flowering, moderate fragrance; dark green leaves; practically non-suckering, 8' high; *S. vulgaris* type.

'Yankee Doodle'—Deepest and darkest purple, 1 to 1 1/5" diameter individual flowers in 8" long panicles, profuse-flowering; upright habit to 8'; *S. vulgaris* type, 'Prodige' × 'Rochester'.

S. pubescens subsp. *julianae* 'George Eastman'—Rich wine-red buds open to deep cerise-pink flowers, color is the same on inside and outside of the petals; a compact 5' high plant with horizontally spreading branches.

LATVIAN CULTIVARS

'Daudzpusīgais Zemzaris'—Single, purple in bud opening purple.

'Dobeles Sapņotājis'—Double, buds purple-violet opening purple-violet.

'Esības Prieks'—Single, buds purple opening violet, fading to red-purple.

'Gaistošais Sāpnis'—Single, buds violet opening violet with silvery white markings.

'Gaiziņkalns'—Double, buds purple, opening purple, fading to red.

'Māte Ede /U/pītis'—Single, buds white opening white.

'Pērļu Zvejnieks'—Single, buds white opening white.

'TTT'—Single, buds violet opening purple-violet.

'Vēstule Solveigai'—Single, buds purple, opening purple, fading to violet.

The above are detailed more fully in HortScience 31(3):327–328 (1996).

PROPAGATION: If only a plant or two are needed simply divide and replant sucker(s); for commercial considerations see *S. meyeri*; tissue culture has been successful with this species. See McCulloch, *Proc. Intl. Plant Prop. Soc.* 39:105–108 (1989), for a good paper on tissue culture propagation of French hybrid lilacs and respectable literature citations on *Syringa* vegetative propagation.

NATIVE HABITAT: Southern Europe. Cultivated 1563.

RELATED SPECIES:

***Syringa ×chinensis* Willd.** — Chinese or Rouen Lilac
(si-ring'ga chi-nen' sis)

LEAVES: Opposite, simple, ovate-lanceolate, 1 1/2 to 3" long, to 1 1/4" wide, acuminate, cuneate or rounded, entire, medium to dark green, glabrous; petiole—1/3 to 1/2" long.

BUDS: Smaller and more refined than those of *S. vulgaris*.

Syringa ×chinensis, also listed as *S. rothomagenensis* Hort., is a hybrid between *S. persica* and *S. vulgaris*.

The shrub is graceful, broad-spreading, round-topped, with arching branches, more delicate and more

profuse in flower than *S. vulgaris*. Grows 8 to 15' tall and as wide.

Flowers are purple-lilac, fragrant, mid-May, borne in large and loose, 4 to 6"

long panicles from the upper nodes producing an elongated, arching, compound

panicle that results in a shroud of color. Have seen excellent plantings in Midwest. One

of the more handsome hybrid lilacs and often spoken of as the first hybrid lilac, originated as

a chance seedling at Rouen, France, 1777. Midway in leaf size and habit between Persian and Common

Lilac. Can become ratty looking like *S. vulgaris* and proper pruning techniques are a must. 'Alba' has light

pink, almost white flowers, actually off-white as I viewed them at Longstock, May 3, 1999; 'Lilac Sunday' is

a fine-textured, 10 to 12' by 10 to 12' shrub with pale purple flowers in small panicles along the length of the

branches, observed the parent plant, quite striking, appeared more lavender-pink, bred by Jack Alexander,

introduced by the Arnold Arboretum; and 'Saugeana' has lilac-red flowers and is more colorful than the

species. The latter is available in commerce. Zone 3 to 7. Variable mildew susceptibility.

***Syringa ×hyacinthiflora* Rehd.** — Early Flowering Lilac
(si-ring'ga hī-a-sin-thi-flō'ra)

Syringa ×hyacinthiflora is the species name for *S. oblata* and *S. vulgaris* hybrids. They were first raised by Lemoine in 1876 but have since been produced by Clarke of San Jose, CA, Dr. Frank Skinner of Dropmore, Manitoba and Elizabeth Preston at the Dominion Experiment Station, Ottawa. They are extremely hardy and flower before the *S. vulgaris* types. The leaves may turn reddish purple in fall. In general they grow to be large shrubs 8 to 10' high and wide (approaching 10 to 12' high and wide). Suitable for Zone 3 to possibly 7; better in cold climates. Considered quite resistant to leaf curl necrosis.

Many cultivars including:

- 'Anabel'—Early-flowering, double, pink, opening to soft white; 10' by 10'; rated excellent by Father Fiala.
- 'Arvid Williams'—Single, fragrant, lilac flowers, 1 1/4 to 1 1/2" wide, lobes recurved, inflorescences large; dark green foliage, disease resistant; 10 to 12' high, practically sucker-free; selected from seedlings grown from open-pollinated seed of 'Clarke's Giant'.
- 'Asessippi'—Single lavender flowers.
- 'Blanche Sweet'—Blue buds opening to whitish blue petals tinged with pink; Father Fiala introduction and rated excellent via his high standards.
- 'California Rose'—Single, clear pink flowers.
- 'Dr. Chadwick'—Single, blue, fragrant flowers; more compact to 8'.
- 'Esther Staley'—Red buds opening to large, single, pink flowers.
- 'Ethel Webster'—Coral pink, late; vigorous grower.
- 'Evangeline'—Light purple, fragrant, double flowers; mildew resistant; 10' by 10'.
- 'Excel'—Single, lilac-lavender (pink), fragrant flowers; relatively low chilling requirement; may prove better in South.
- 'Fantasy'—Fragrant, double, medium to deep purple flowers; 10 to 12' by 10 to 12'; developed by W.E. Clarke.
- 'Luo Lan-Zi'—Red-purple buds opening to blue-purple, double flowers.
- 'Maiden's Blush' ('Maiden Blush')—Pink to lavender-pink, fragrant flowers; excellent foliage turns burgundy in fall; 10 to 12'.
- 'Minnehaha'—Single, bishop's-purple flowers.
- 'Mt. Baker'—White, single, fragrant flowers; mildew resistant; 10 to 12' by 10 to 12'.
- 'Pocahontas'—Deep maroon-purple buds open to deep violet, fragrant, single flowers; 10 to 12'.
- 'Purple Glory'—Fragrant bluish purple flowers with deep green foliage.
- 'Royal Purple'—Deep royal-purple, early, double flowers; 10' by 10'.
- 'Sister Justena'—Single, white flowers.
- 'Swarthmore'—Lilac-purple, fully double flowers, reliable flowering; extremely hardy.
- 'Vaiga'—Single, pink to grayish white, fragrant, 1 to 1 1/4" diameter, large panicles; good green, disease resistant foliage; 7' high; moderate suckering; from open-pollinated 'Esther Staley'.
- 'Vesper Song'—Single, violet flowers; rounded habit, 10' by 10'; rated excellent by Father Fiala.
- 'Xiang Xue'—Double, white, fragrant flowers.
- 'Zi Yun'—Blue-purple buds opening to pink-purple flowers, corolla tube blue-purple.

***Syringa ×laciniata* Mill. — Cutleaf Lilac**
(si-ring'ga lā-sin-ē-ā'ta)

LEAVES: Opposite, simple, all or partly 3- to 9-lobed, 1 to 2 1/2" long, 1/2 to 3/4 as wide, blue-green, glabrous, very interesting and different leaf texture for a lilac; first leaves always lobed, later often not.

Syringa ×laciniata is a somewhat confused entity and at one time was listed as a variety of *S. ×persica*, maybe *S. protolaciniata* × *S. vulgaris*. The habit is low, dense, rounded-mounded and 6 to 8' high. With age, plants form colonies of a suckering nature. The small, pale lilac, fragrant flowers are borne in 3" long, loose panicles all along the stems in May. The lacy, fine-textured foliage is an unusual asset and quite striking when one considers the usual foliage complement of most *Syringa*. Hardy to at least Zone 4 as I have seen a thriving specimen in the Wisconsin Landscape Arboretum. It is one of the best lilacs for Zone 7(8) conditions and is frequently encountered in Athens and Atlanta, GA where it flowers in late March—early April. Displays excellent heat tolerance and will provide reliable flower in partial shade. Leaves are highly mildew resistant. Considered native to Turkestan and China. This form is largely sterile while another introduction, *S. protolaciniata* P.S. Green & M.C. Chang, is fertile. See *Kew Magazine* 6(3):116–124 (1989). Also, Vrugtman lists *S. protolaciniata* 'Kabul' that was introduced to Kew Gardens from gardens in Kabul, Afghanistan and erroneously named *S. afghanica*. The corolla lobes are longer (about 1/3") than the original introduction from China. A great lilac for Zone 7 and is relatively common in Athens. I have yet to witness fruits. Perhaps crosses to *S. pubescens* subsp. *patula* 'Miss Kim', assuming viable pollen, would lead to a new group of *relatively* heat-tolerant lilacs.

***Syringa oblata* Lindl. — Early Lilac**
(si-ring'ga ob-lā'ta)

LEAVES: Opposite, simple, orbicular-ovate to reniform, often broader than long, 2 to 4" broad, to 3" long, abruptly acuminate, cordate to subcordate, entire, glabrous, dark green, almost bluish green, emerging leaves bronze-tinted; petiole—3/4 to 1" long.

Syringa oblata is a large (10 to 12') shrub or small tree related to *Syringa vulgaris*. The young leaves are often bronzish and change to dark green in summer followed by muted reddish to reddish purple tones in fall. The pale to purple-lilac flowers occur in rather broad, 2 to 5" long panicles from the upper-most nodes of the previous year's wood in April–May, usually opening 7 to 10 days ahead of *S. vulgaris*, typically opening in late March–early April, Athens. This is a rather coarse lilac but is valuable for breeding work as well as the rather handsome fall color. Northern China. Introduced 1856. Zone 3 to 6. Subspecies *dilatata* (Nak.) P.S. Green & M.C. Chang is more common and tends to be smaller, shrubbier, with longer leaves and a longer, more slender corolla tube than the species. Full flower March 24, 2009 at Raulston Arboretum, quite fragrant and showy. 'Frank Meyer', almost side-by-side, was just pushing forth leaves. I had the subspecies in my Illinois garden and have seen it at the Arnold and University of Maine where the bronzy red to purple fall color was quite beautiful. It has proven reliable in Raleigh, NC, with early and profuse-flowering every year. Alba Group houses white flowered forms where 'Frank Meyer' and 'Betsy Ross' are slotted. The former is a robust, 10' high and wide shrub with early, white, fragrant flowers in loose panicles; the latter with sweet, glistening white, fragrant flowers in tighter panicles. 'Betsy Ross' is a U.S. National Arboretum release but has not proven well-adapted to Athens conditions. Leaves out early with emerging leaves evident in late March; leaves starting to discolor in July. Resulted from a cross made in 1977 by Dr. Egolf using *S. oblata* collected in China as male parent times an unidentified *Syringa* from Highland Park, Rochester. Much better than *S. vulgaris* white cultivars for the South. Released in 2000 by the USNA. 'Cheyenne' produces pink buds that open to single blue flowers; excellent bronze to burgundy-red fall color. 'Declaration' produces fragrant reddish purple flowers in up to 15" long panicles. The original 25-year-old parent plant was 8' high with an open, upright growth habit. Recommend for Zone 6 and cooler. 'Old Glory', with fragrant, bluish purple flowers forms a rounded habit about 10' by 10' in 25 years. Foliage displays good tolerance to *Cercospora* blight and *Pseudomonas syringae* in warmer climates. USNA introduction along with 'Declaration' and 'Betsy Ross'. 'Wan Hua-zi' has single, purple-pink flowers about 15 days later than *S. oblata*, tolerant of summer heat and humidity as well as to winter cold and aridity; see *HortScience* 32(4):587–588 (1997). See *Hortscience* 43:544–545 (2008) for 'Betsy Ross', 'Declaration', and 'Old Glory'. Korea. Introduced 1917. Zone 3 to 6.

Syringa xpersica L. — Persian Lilac
(si-ring'ga pēr'si-ka)

LEAVES: Opposite, simple, lanceolate or ovate-lanceolate, (rarely 3-lobed), 1 to 2 1/2" long, 1/3 to 1/2"(3/4") wide, acuminate, cuneate, entire, dark green above, glabrous, often infested with mildew to a degree that the leaves assume a whitish cast; petiole—1/3" long.

Syringa xpersica is a graceful shrub with upright, arching, slender branches reaching 4 to 8' in height and spreading 5 to 10'.

The foliage is dark green and may contract mildew. Flowers are pale lilac, fragrant, mid-May (has opened from early to late April, Athens), borne profusely in 2 to 3" long and wide panicles from the upper nodes of the previous season's growth. A nice small lilac with a mass of flower when properly grown, good plant for the shrub border. Cultivated since time immemorial. Introduced 1614. Zone 3 to 7. May be a hybrid between *S. laciniata* and *S. vulgaris* since it is almost completely sterile and probably has not been found wild in any country. 'Alba' is a white-flowered form; 'Rosea' and 'Rubra' with light to dark pink flowers, respectively.

ADDITIONAL NOTES: Five of the finest lilac collections I have observed are located at the Arnold Arboretum; Royal Botanic Garden, Hamilton, Ontario, Canada; Swarthmore College; Highland Park, Rochester, NY; and the Minnesota Landscape Arboretum. Species approach 20 or more and are not the easiest taxa to separate by vegetative characteristics. Great tirades in the literature discuss the need for near neutral to neutral (sweet) soils for best growth. Perhaps, but in the acidic soils of the Northeast, numerous specimens could attest to the opposite. Simply food for thought. You may read the literature, plants generally do not. Tremendous interest in heat tolerant lilacs. To my knowledge there is no such thing for Zone 8 and 9. Most *S. vulgaris* clones languish in Zone 7. I am not sure every plant has to grow everywhere! International Lilac Society, www.internationallilacsociety.org, is a society for like-minded, fragrant people.

Taiwania cryptomerioides Hayata — Taiwania or Coffin Tree

(tī-wan'ē-a krip-tō-mē-ri-oy'dēs)

FAMILY: Cupressaceae, also placed in Taxodiaceae

LEAVES: Alternate, 1/3 to 1/2" long, sickle-shaped, extremely sharp-pointed, blue green, spiraling and fully clothing the stem.

Taiwania cryptomerioides, Taiwania or Coffin Tree, first came into my horticultural purview when visiting Callaway Gardens in 1979. This first meeting produced a never-forgotten first encounter of the prickly kind. The sharp-pointed needles are forever embedded. New growth is light blue-green and contrasts handsomely with the darker blue-green mature needles. Habit is quite beautiful, especially young trees, softly pyramidal-conical, the branches almost layered upon each other in graceful descending fashion. In the wild, listed as reaching 150' and greater. The largest tree observed in the Southeast was about 30'. The Raulston Arboretum and Atlanta Botanical Garden have respectable specimens that have withstood the recent heat and drought. Male and female cones occur on the same tree. The female cones cylindrical in outline and about 1/2" long. Most literature ascribes moist, well-drained soil and a protected site for best performance. Will *never* become truly commercial but worthwhile for the collector. *Taiwania flousiana* Gaussen is occasionally encountered and is quite similar to *T. cryptomerioides*. The needles are less prickly, but I don't feel much difference. Also considered hardier than *T. cryptomerioides* but recent literature lumps it with *T. cryptomerioides*. Southwestern and central China, Myanmar. Zone 7, 8 to 9 on West Coast. *Taiwania cryptomerioides* is found in Taiwan. Zone 7, 8 to 9 on West Coast. Introduced 1920 by E.H. Wilson. Might mention that in 1995, I photographed a beautiful specimen at UBC Botanical Garden, Vancouver. The tertiary branches hanging like blue curtains. UBC reported wild-collected material from three sites in Taiwan that for over 20 years never suffered frost damage. These trees now range from 30 to 40' high and have yet to produce female cones.

Tamarix ramosissima Ledeb. (formerly listed as *T. pentandra* Pall.) — Five-stamen Tamarix or Tamarisk

(tam'a-riks ram-ō-sis'i-ma)

FAMILY: Tamaricaceae

LEAVES: Alternate, simple, lanceolate to ovate, 1/8" long, acute, glaucous, small, usually scale-like, bright green, similar to juniper foliage.

BUDS: Small, sessile, rounded, compressed against twig, solitary or quickly becoming concentrically multiple, with about 3 exposed scales.

STEM: Slender, elongated, rounded; pith—small, rounded, continuous.

SIZE: 10 to 15' high, usually less in spread, have observed 20 to 25' high specimens along North Carolina and Georgia coasts.

HARDINESS: Zone 3 to 8; the hardiest species of *Tamarix*; Cappiello mentioned some tip dieback at Orono, ME.

HABIT: Usually a wild growing, very loose, open shrub; can be attractive with its fine-textured foliage, but definitely needs to be hidden when defoliated.

RATE: Fast.

TEXTURE: Fine in foliage; needs to be disguised in winter (coarse).

LEAF COLOR: Light green, scale-like; creating a feathery appearance; some forms and species are glaucous green, blue-green to bluish.

FLOWERS: Perfect, rosy pink, 5-petaled, 5-sepaled, borne in dense or slender, 1 to 3" long racemes which form large, terminal panicles, June–July; quite attractive, the entire flowering shoot may approximate 3' in

length; normally in full flower by early to mid-April in Athens; flowering on May 1, 1998 at Biltmore Gardens, Asheville, NC; flowers on new growth of the season.

FRUIT: Capsule, inconsequential.

CULTURE: Root systems are usually very sparse and, for this reason, care should be exercised in planting; container-grown plants are the best bet; prefer acid, well-drained, low fertility soil; full sun; not really particular as to soil and can grow in sand; ideal for seashore plantings as they are fantastically salt tolerant; prune back this species in early spring since it flowers on new growth; I have observed heavy flowering on plants that were pruned to the ground the previous winter; however, from the early flowering date in the South, it is obvious that flowers arose from previous years buds; apparently the plant can go both ways which is somewhat unusual; have observed 25' high plants growing in pure sand less than 100 yards from the Atlantic Ocean on Georgia's St. Simons Island; indeed saline and dry soil tolerant.

DISEASES AND INSECTS: Cankers, powdery mildew, root rot, wood rot, and scales.

LANDSCAPE VALUE: Interesting for foliage effect as well as flowers but its uses are limited; perhaps best reserved for saline environments where it does amazingly well; have seen it used at Cantigny Gardens, Wheaton, IL where it had been treated like an herbaceous perennial to stimulate vegetative growth; for textural quality it is beautiful when handled this way; the flowers may last 4 to 6 weeks but show their age toward the end of the cycle; a particularly fine specimen resides at the Bridge of Flowers, Shelburne Falls, MA and flowers in mid to late July.

CULTIVARS:

'Cheyenne Red'—Deeper pink flowers than the species.

'Pink Cascade'—Slightly richer pink flowers than 'Rosea' and is quite vigorous.

'Rosea'—Rosy pink flowers, each 1/8" across, arranged in slender, variable length (1 to 5" long) racemes, flowers occur late and may develop in July–August in the North; considered one of the hardiest cultivars; ideally cut back in late winter and a 6 to 10' tall plant will bear profuse flowers in mid to late summer.

'Rubra'—Deeper pink flowers than the species; a branch sport of 'Rosea'.

'Summer Glow'—Dense, feathery, blue-tinged foliage; rangy, splaying, irregular habit; bright rose-pink flowers; 10'(15') full flower early June, Spring Grove, Cincinnati, mid-July, Minnesota Landscape Arboretum.

PROPAGATION: Fresh seeds usually germinate within 24 hours after imbibing water; no pretreatment is necessary; softwood cuttings, placed in peat:perlite under mist root easily; the rooting may be sparse and the roots coarse and somewhat difficult to handle; hardwood cuttings can also be rooted.

ADDITIONAL NOTES: This genus does not require high fertility soils, and I have noticed decline in container-grown specimens under high nutritional status. The plants also become more open and leggy than normal when grown under high fertility. This is a genus which has a distinct place when salt presents a cultural problem. The entire genus is rather taxonomically similar and from a landscape viewpoint there is little to differentiate the species, unless one considers the type of wood upon which the flowers are borne. In August, several students and I were hiking through Hidden Lake Gardens, Tipton, MI and came upon a 25' high and 25' wide, flowering specimen of *T. ramosissima*, or so I spouted until my graduate student read the label . . . *T. africana* Poir., . . . as I said, not the easiest plants to separate . . . ahem! Indeed, my continued literature searches indicate the Hidden Lake Gardens species was not *T. africana*.

Other species that appear in gardens and literature include: *Tamarix chinensis* Lour. (previous year's wood), *Tamarix gallica* L. (current year's wood), and *Tamarix tetrandra* Pall. ex M. Bieb. (previous year's wood). Some indication that *T. chinensis* may be the most common form in cultivation, also in Southeast. National champion is 45' by 50' in Albuquerque, NM. I have read that *T. chinensis* is synonymous with *T. ramosissima*; GRIN treats them as a separate species, which makes sense since they flower on old and new growth, respectively. Approximately 50 species are described from western Europe and the Mediterranean to eastern Asia and India. I suspect the ranges overlap and like our native deciduous eastern United States azaleas they are difficult to differentiate.

The deciduous, Asiatic *Tamarix* species have invaded and replaced most of the native vegetation on over 1,000,000 acres of wildlife and agricultural land in riparian ecosystems of the western United States. Numerous research papers on control strategies for eliminating *Tamarix* species in the western states have been published.

NATIVE HABITAT: Southeastern Europe to central Asia where it usually occurs on saline soils. Cultivated 1883.

RELATED SPECIES:

Tamarix parviflora DC., (tam'a-riks pār-vi-flō'ra), Small-flowered Tamarix, grows 12 to 15' high, flowers on previous year's growth and should be pruned immediately after flowering. The 4-petaled, 4-sepaled flowers are light pink and usually develop in late May through early June. Considered the most easily recognized because of floral parts in 4's, rather than 5's in all other species. Native to southeastern Europe. Cultivated 1853. Zone 4 to 8.

Taxodium distichum (L.) Rich. var. *imbricarium* (Nutt.) H.B. Croom (formerly *Taxodium ascendens* Brongn.) — Pondcypress (Deciduous), also called Pond Baldcypress
(taks-ō'di-um dis'ti-kum im-bri-cār'ē-um)

FAMILY: Cupressaceae

IDENTIFICATION CHARACTERISTICS: Similar to *T. distichum* (q.v.) except bark is light brown and deeply furrowed; deciduous branchlets erect; leaves appressed or incurved, awl-shaped, 3/8" long, bright green, rich brown in autumn.

SIZE: 70 to 80' in height, probably 15 to 20' wide; national champion 100' by 10' in Pierce, GA.

HARDINESS: Zone (4)5 to 9(10 and 11).

HABIT: Narrowly conical or columnar with spreading branches and erect branchlets; a deciduous conifer.

RATE: Slow to medium (18' in 20 years); sufficient evidence to indicate that with ample moisture and fertility, 2' of growth per year in the early years is possible.

TEXTURE: Fine in foliage; medium in winter.

LEAF COLOR: Bright green changing to rich brown (orangish brown) in autumn; late leafing, as late as late May—early June in the Midwest; fall color has also been described as fox red, perhaps through the eyes of a fox.

FLOWERS: Monoecious; male flowers ovoid, forming terminal and drooping panicles; female flowers scattered near the ends of branches of the previous year, sub-globose; male flowers appear as slender, pendulous catkins (4 to 5" long, branched, spikose panicle), often more prevalent in the upper reaches of the tree, March–April.

FRUIT: Cones short-stalked, globose or ovoid, 1/2 to 1 1/4" across, purplish and resinous when young, ripening the first year and turning brown.

CULTURE: Nurserymen mentioned that the tap root makes this and *T. distichum* difficult to transplant; however, suspect root pruning at an early age would alleviate the problem; have seen far too many successfully transplanted specimens; adaptable, prefers moist, acid soils; performs well on upland soils; full sun and open areas, extremely wind firm; have used this and the species in great quantities in my consulting work and have never lost a tree; often grown in containers and quite easy to transplant.

DISEASES AND INSECTS: Mites and gall, more problematic on *T. distichum*.

LANDSCAPE VALUE: Specimen for parks, large areas, wet and dry places; I used to look at this species as totally secondary to *T. distichum* but have questioned my conventional wisdom in recent years; have seen groves, groupings, isolated specimens and leave with strong positive impressions; tree is decidedly columnar compared to *T. distichum* with scaffold (secondary branches originating at right angles to central leader); also have not noticed the gall on this species which is common on *T. distichum*; the common species on the Western side of the Okeefeenokey Swamp and a magnificent site to behold; Mike Buffin, former curator at Hillier and I toured the swamp in late January, the alligators sluggish (good) and sunning themselves on the banks, the water brown-black, the *Pieris phillyreifolia* (Hook.) DC, with its evergreen leaves, growing under and through the bark, vine-like in habit; the same species forming a small shrub with large leaves on terrestrial sites in the park.

CULTIVARS:

'Carolyn'—Rapid growth, uniformity in branching, pyramidal habit; a form of var. *imbricarium* introduced by John Malone, Summer Shade Nursery, GA, and named after his lovely wife.

Debonair®—('Morris', PPAF)—Soft, pyramidal selection of the native Pondcypress; medium green foliage turns bronze in autumn; more open and feathery than 'Prairie Sentinel'; withstood –28°F; evaluated for 37 years by Mr. Earl Cully before release; Heritage® Trees, Inc. introduction.

'Homer'—Bright green summer foliage; needles longer and densely set, curled, feather-like, russet-gold fall color; introduced by John Malone, Summer Shade Nursery, GA.

'Nutans'—Branches short, horizontal, some ascending parallel with the trunk; branchlets crowded, closely set, more or less pendulous.

'Prairie Sentinel'—An Earl Cully, Jacksonville, IL introduction; very tall in relation to width, 60' tall and 10' wide with very soft, fine-textured foliage; does well on upland soil and on very moist sites; Mr. Cully mentioned that the selection was not particularly cold hardy, but it has withstood –24°F at Bernheim Arboretum; the late Mr. Buddy Hubbuch, Horticulturist, Bernheim, planted this, 'Shawnee Brave' and 'Monarch of Illinois' in a large planting by the entrance side of the lake; I have observed it in winter, summer and fall . . . truly beautiful beyond words.

PROPAGATION: *Taxodium* seeds exhibit an apparent internal dormancy which can be overcome by 90 days of cold stratification; softwood cuttings have been rooted but success is variable and, doubtfully, commercially viable; hardwood cuttings have been used in England; grafting is the most reliable method for reproducing the cultivars, with bench grafting using 2- to 3-year-old seedlings, whip-and-tongue graft, and allow to heal at 55 to 60°F; see *The Plant Propagator* 9(1):11 (1962) and *Proc. Intl. Plant Prop. Soc.* 17:376 (1967).

- ADDITIONAL NOTES:** The late Dr. Wilbur Duncan noted that hybrids exist between this and *T. distichum*. Morphologically, the two taxa are quite unique. The “knees” supposedly do not form to the degree they do on *T. distichum*.
- NATIVE HABITAT:** Virginia to Florida and Louisiana, on more upland areas, i.e., around ponds rather than in them, although the two species occur in mixed company. Certainly in the water in the Okefeenokee. Cultivated 1789.

Taxodium distichum (L.) Rich. — Common Baldcypress (Deciduous)

(taks-ō'di-um dis'ti-kum)

- LEAVES:** Spirally arranged on the branchlets, 2-ranked on the deciduous shoots (branchlets), linear-lanceolate, apiculate, 1/3 to 3/4" long, 1/16 to 1/12" wide, bright yellow-green in spring, soft sage green in summer, rich orange to pumpkin brown in autumn.
- BUDS:** Alternate, near tip of stem rounded, with overlapping, sharp-pointed scales; smaller lateral buds also present, and from them leafy, budless branches (branchlets) arise which fall in autumn.
- STEM:** Of two kinds: later branchlets green, deciduous; young branchlets green, becoming brown the first winter.
- SIZE:** 50 to 70' high by 20 to 30' wide, can grow to 100' and more; co-national champions are 96' by 74' in Cat Island, LA and 82' by 65' in Holmes, MS; over 60' high tree in Morton Arboretum.
- HARDINESS:** Zone 4 to 11; Baldcypress has been planted far north of its natural range; there are specimens in Minnesota, southern Canada and a few old trees in Syracuse, NY; some of these trees have withstood temperatures of -20 to -30°F; Cappiello reported outright kill in Orono, ME.
- HABIT:** A lofty, deciduous conifer of slender, pyramidal habit, almost columnar in youth, with a stout, straight trunk buttressed at the base and short, horizontal branches, ascending at the ends, the lateral branchlets pendulous; sometimes becoming irregular, flat-topped and picturesque in old age.
- RATE:** Medium, 50 to 70' high in 30 to 50 years; amazing growth rate in Wichita, KS tests where it averaged 2'7.4" per year over a 9-year period.
- TEXTURE:** Medium-fine in leaf, medium in winter.
- BARK:** Rather attractive reddish brown, fibrous bark; the trunk becoming strongly buttressed especially in wet areas; I have observed specimens in the Coastal Plain of Georgia growing in wet areas that were magnificent; there is something hauntingly beautiful about a “grove” of Baldcypress; it should be mentioned that the “cypress knees” occur only near water or in exceedingly moist soils; I have not seen them on trees planted under normal conditions in cultivation; it has been shown that the “knees” are not necessary for gaseous exchange.
- LEAF COLOR:** Bright yellow-green in spring; it darkens in summer to a soft sage green; in autumn it becomes a russet, soft brown to a mellow orangish brown, fall color occurs about mid-November with some needles still present in early December, Zone 7; some needle injury after 26°F freeze over Easter Weekend, April 6–7, 2007.
- FLOWERS:** Monoecious, staminate in drooping, 4 to 5" long panicles; March–April; pistillate cones are subglobose, comprising several spirally arranged peltate scales, each bearing 2 erect, basal ovules.
- FRUIT:** Cones globular or obovoid, short-stalked, approximately 1/2 to 1"(1 1/2") across, green to purple and resinous when young; brown at maturity, mature in one year; seed triangular, to 1/2" long.
- CULTURE:** Transplants readily balled-and-burlapped as a small, root-pruned, nursery-grown plant; see comment under *T. distichum* var. *imbricarium*; makes it best growth on deep, fine, sandy loams with plenty of moisture in the surface layers and moderately good drainage; in the wild it is seldom found on such places and occurs primarily in permanent swamps where it forms pure stands; very adaptable tree to wet, dry and well-drained soil conditions; requires a sunny location; soils should be acid for chlorosis will occur on high pH soils; several trees on the Illinois campus were almost golden yellow and when treated with a trunk injection of ferric ammonium citrate they greened up within a month, however, treatments often have to be repeated; exceptionally wind firm and even winds of hurricane force rarely overturn them.
- DISEASES AND INSECTS:** Twig blight, small annual cankers caused by *Seiridium* were reported on landscape plants in Kansas, see *Plant Disease* 75(2):138–140 (1991), wood decay, cypress moth, fruit tree leafroller (*Archips argyrospilus*) reached outbreak densities in Louisiana, gypsy moth larvae feeding was reported in Maryland, spider mites, and a gall forming mite.
- LANDSCAPE VALUE:** A stately tree, a decided accent of texture and form; in parks or large estates it makes a distinctive specimen; good for wet areas; possibly a worthwhile highway plant or street tree; have seen used in groupings and groves around lakes and the effect is spectacular; interestingly the knees form in the shallow water at lake's edge and seldom on the land side; have planted extensively at the Milliken

Arboretum, Spartanburg, SC in the water, on the shore and on upland sites, all have prospered; over an 18-year period, *T. distichum* was one of the most highly rated trees (out of 200) in the Auburn University test, see *J. Arboriculture* 21(3):118–121 (1995) for specifics; also, Nash and Graves, *J. Amer. Soc. Hort. Science* 118(6):845–850 (1993), showed *T. distichum* one of the most photosynthetically active species during flooding.

CULTIVARS:

'Apache Chief'—Wider, beautiful; from Klehm Nursery, Illinois.

Autumn Gold™ ('Sofine', PP 13,431)—Relatively compact-pyramidal selection with sage-green foliage, rust-orange fall color, have seen the plant in October at PDSI/Flowerwood, Loxley, AL; excellent habit and southern growers mentioned it was a good form.

'Cascade Falls' (PP12,296)—Almost passed out when I first learned about this weeping form from New Zealand, introduced by Cedar Lodge Nursery, brought to the United States by Larry Stanley, Stanley & Sons Nursery, Boring, OR; wants to grow as a groundcover and requires staking initially, appears to outgrow this tendency and produce upright-arching branches; a large, 20' high plant in Coach Vincent Dooley's garden, Athens, is now (2009) a magnificent specimen.

Contorted Form—Stems contorted, thicker than usual, leaves more evergreen; discovered by Michael Richard, Live Oak Gardens, New Iberia, CA; Michael sent me a photograph in 2001, quite striking.

'Falling Waters'—Another weeper but it develops a leader, the secondary branches cascading; have only observed small plants and they perform as described; I believe this came originally from Germany.

'Fastigiata'—Columnar form, supposedly more upright and narrow than the species; listed by Stanley & Sons Nursery, Boring, OR.

Heritage® ('Nelson', PP 12,502)—Distinct broad pyramidal habit of growth; dark green foliage; high resistance to insect pests, particularly twig gall and eriophyid mite; cold hardy, strong branches, and rapid growth; selection from about 20,000 seedlings from southern Illinois source, evaluated since 1978; survived –28°F; more loose, open and softly textured than Shawnee Brave®, developed and patented by Earl Cully, Jacksonville, IL; Heritage® Trees, Inc. introduction.

'Hursley Park'—Described as a dwarf, dense shrub that originated on a tree at Hursley Park, Hampshire, England.

'Monarch of Illinois'—Truly a handsome specimen; wide-spreading, the parent tree had a limb spread of 65' and a height of 85'; this type of growth habit is unusual for this species; my observations indicate this form is not as desirable as 'Shawnee Brave' because of squattier growth and greater mite susceptibility.

'Pendens'—Pyramidal form, branches nearly horizontal, nodding at the tips, branchlets drooping; have seen photos of this clone and the form represented was broad pyramidal with distinct semi-arching branches.

'Peve Minaret'—Tight, upright, dense habit, possibly 10' by 3 to 3 1/2'; needles closely spaced along stems creating different texture; surreal pygmy-forest effect; large fattened trunk for such a tiny tree; branches feather-like, upswept, producing a tight cone; a plant in the Dirr Chapel Hill garden is certainly eye-catching.

'Peve Minaret Yellow'—Yellowish needles but more open in habit and simply not as attractive as 'Peve Minaret'.

'Secrest'—A "witches' broom" of the species; discovered in the Secrest Arboretum, Wooster, OH; has golden fall color; grows 3 to 6" a year, matures 1' by 4'; abysmally ugly.

Shawnee Brave® ('Michelson')—Form with narrow pyramidal habit; parent tree was 75' tall and 18' across; has street tree and single specimen possibilities; 20' high trees in Spring Grove that were beautiful; foliage deep sage green and mite resistant; utilized to line a road at Milliken Research Corporation, Spartanburg, SC, the original 12' trees now 30', tight pyramidal, forming a beautiful allée; an Earl Cully introduction.

Witch's Broom Selections—I have seen many dwarf types, primarily derived from witch's brooms; 'Cave Hill', 'Hursley Park', 'Little Leaf', 'Little Twister', 'Schloss Herten' and 'Secrest' fall in this milieu; Pat McCracken, Zebulon, NC amazes me with his collection of all things *Taxodium*; see www.mccrackennursery.com.

PROPAGATION: As previously discussed under *T. distichum* var. *imbricarium*. I have rooted cuttings with 30 to 40% success using very soft growth, 1,000 ppm IBA, peat:perlite, mist. Solid case for juvenility in *New Forests* 8(4):381–386 (1994) where cuttings of 1- or 25- to 50-year-old trees were untreated or treated with 1,000 ppm IBA. Rooting was 75% for IBA-treated 1-year-old trees; 12% for 25- to 50-year-old trees. *Tree Planters Notes* 44(3):125–127 (1993) reported 58% rooting of 23-year-old clones.

ADDITIONAL NOTES: Years past, I journeyed to Germany and visited gardens and parks with the denominator being *Taxodium distichum* in common use. Many trees were easily 50 to 60' high and a match for plants in the wild. The Germans are great at reproducing habitat gardens and *T. distichum* was used with other plants of wet soil or geographical affinity. In fact, as I write this, the wonderful *Planten und Blumen* in Hamburg comes to mind with a tremendous number of *T. distichum* reflecting a southeastern habitat.

Interestingly, the plant is usually columnar to pyramidal without great variation but I have seen trees with broad-spreading canopies. Note the dimensions of the national champion. Many years past I walked the Kansas State University campus with Dr. Steve Still and could not reconcile the broad-spreading habit. Also, this is often the common habit in swamps along I-95 through coastal Georgia, the plants often draped with Spanish moss. Amazing plants in San Antonio, TX along the River Walk, some 100' high. Common in Houston, TX and obviously growing with abandon.

NATIVE HABITAT: Delaware to Florida, west to southern Indiana, Illinois, Missouri, Arkansas, Louisiana, and Texas. Introduced 1640.

RELATED SPECIES:

Taxodium mucronatum Ten., (taks-ō'di-um mū-krō-nū'tum), Mexican Baldcypress, occasionally surfaces in southeastern gardens but is definitely inferior to the previous species. I have observed cold damage on the specimen at Raleigh, NC and suspect it does not shut down (harden) early in fall and/or initiates cambial activity too early in spring and is injured by late fall or early spring freezes, respectively. Technically evergreen to semi-evergreen, but deciduous in Raleigh. On December 19 some leaves were green, others brown; all leaves had abscised on *T. distichum* var. *imbricarium* and *T. distichum*. Appears wider spreading at an early age, i.e., more bushy. National champion is 68' by 99' in Cameron County, TX. Article in *Arnoldia* 57(4):2-11 (1998) discusses "The Ancient Giant of Oaxaca," the tree some 130' high with 200' trunk circumference. Mexico. Zone 8 to 10. Dr. David Creech, Stephen F. Austin University, traveled to China and witnessed hybrids of *T. mucronatum* and *T. distichum*, considered more high pH/alkaline-soil-tolerant than the latter. Dave gave me a small rooted cutting that in the Georgia trials grew 18' by 6 to 8' with a 6" trunk diameter in 5 years. Definitely shows hybrid vigor. I believe this is designated 'Nanjing Beauty'.

Taxus L. — Yew

FAMILY: Taxaceae

Taxus includes the highest quality needle-type evergreens in landscape use. The quality characteristics include slow to medium growth rate, resistance to insects and diseases, excellent year-round color, wide variations in form, compact growth habit, winter hardiness, and ease of propagation. *Taxus canadensis* Marsh., *Taxus floridana* Nutt. ex Chapm., and *Taxus brevifolia* Nutt. are native to this country, however, the important ornamental cultivars are found in the species *T. cuspidata* and *T. xmedia* with a few excellent types in the species *T. baccata*. Many of the *T. baccata* types are tender and may be damaged or discolor during winter in colder areas. In addition to the factors mentioned above, the colorful red seed is an effective ornamental feature on some cultivars. Literature has it that Robin Hood made his bows from the yew tree. Yew wood is beautifully grained and I purchased a chair fashioned from English yew that is too beautiful to sit in.

Unfortunately, the nomenclature of *Taxus* is as confused as any genus. This has come about because of the lack of distinguishing features between cultivars, and the indiscriminate naming of cultivars. This problem is particularly serious in the *T. cuspidata* and *T. xmedia* types, whereas the naming of *T. baccata* types, which have been under cultivation for hundreds of years, is less confused. A collection of *Taxus* was begun at the Ohio Agricultural Research and Development Center in Wooster in 1942. This collection, containing over 100 cultivars, is the largest in the world and is intended to serve as a base for selecting outstanding forms which, after positive identification, are being disseminated throughout the world.

The various taxonomic treatments list 3 to 10 species worldwide and hint at the ambiguity in separating them into discrete phenotypic (and genetic) entities. I have, along with my former graduate student, now Dr. Donglin Zhang, accumulated *T. floridana* Chapm., Florida Yew; *T. globosa* Schltldl., Mexican Yew; *T. sumatrana* (Miq.) de Laub.; *T. wallichiana* var. *chinensis* (Pilger) Florin, Chinese Yew; and *T. wallichiana* var. *mairei* (Lemée & Lév.) L.K. Fu and Nan Li with the hope of unearthing a heat tolerant species. Dr. Raulston showed that *T. wallichiana* var. *chinensis* was well-adapted in Raleigh and this is true in Athens. Does discolor in full sun, particularly in winter. Small plants in the Morton Arboretum have been severely browsed by deer. Gigantic var. *mairei* at Sarah P. Duke Gardens now 20' high and 20' wide with lustrous dark green needles. Certainly no consistency in the nomenclature of these species.

One of the looming problems for *Taxus* in the contemporary landscape is DEER susceptibility. My travels through the Midwest and East have provided endless evidence for the seriousness of deer browsing. Morton Arboretum noted that deer browse to the point of killing the plants with no harm to the deer. The Horticultural Research Institute awarded significant money to the University of Rhode Island to develop methods to reduce deer feeding on landscape plants. See discussion under *Taxus baccata* ADDITIONAL NOTES.

MORPHOLOGICAL CHARACTERISTICS

Evergreen trees and shrubs with reddish to brown bark and spreading and ascending branches. Branchlets are green. Leaves are glossy or dull dark green above, lighter green below, flat and needle-like, abruptly pointed or tapering and acute. *Taxus baccata* types usually have sickle-shaped leaves. Leaves are arranged radially or in a flat plane. Winter buds are small and scaly. With rare exceptions, plants are dioecious with the *male flowers globose* and the *female flowers appearing as small stalked conical buds*. The seeds are brown and nut-like, covered by an attractive fleshy, red aril, ripening the first year; cotyledons 2. If one is interested in securing "fruiting" plants, the morphological differences italicized above are worth remembering.

GROWTH CHARACTERISTICS

Wide variation in habit, size, growth rate, and textural effects occurs. Practically all cultivars are compact and retain a dense character with age without extensive pruning. In addition to overall form, line and textural effects vary because of differences in branching habit and degree of compactness. Foliage color is essentially dark green with some variations to lighter greens and a few cultivars with yellow foliage. *Taxus* retain high quality characteristics indefinitely and, under good conditions, will continue to increase in value with age.

CULTURE

Taxus are most effectively moved balled-and-burlapped and can be planted in spring or fall with good success. Some growers are producing container yews and this represents an alternate choice to balled-and-burlapped specimens. However, most yews are field-grown, then dug and placed in containers for ease of handling during the marketing process. Yews require a fertile soil, sufficient moisture, and *excellent* drainage. Anything less than *excellent* drainage results in growth reductions or death of yews. Yews do equally well in sun or shade but should be kept out of sweeping winds. Often, in winter, the needles will brown or yellow because of desiccation. All, except some of the *T. baccata* cultivars, are reliably hardy in the Midwest and Northeast. Very few yews are used in Minnesota and areas with similar low temperatures. Conversely, yews are seldom used in the southern states for they do not tolerate the extreme heat. Several garden designers have reported success in the Atlanta area but for large scale corporate landscapes, the plant should not be used. One species, *Taxus floridana*, Florida Yew, occurs in a narrow area along the Apalachicola River in northwestern Florida. It becomes almost tree-like and may grow 20 to 24' high. The national champion is 22' by 23' in Liberty County, FL. There is a fine specimen at the Biltmore Estate, Asheville, NC and the Atlanta Botanical Garden.

Many of the cultivars are naturally compact and symmetrical and relatively little corrective pruning is necessary. *Taxus* can be pruned severely and it is possible to maintain plants at determined sizes and shapes by frequent pruning or shearing. This is particularly advantageous in the culture of formal *Taxus* hedges or screens where early spring pruning followed by removal of "feather growth" in the summer will maintain the desired form. Although it is common practice to shear *Taxus* into tight, formally shaped plants, more interesting and attractive plants will result from pruning rather than shearing to retain the natural habit and appearance of the cultivar. The tight pruning results in the formation of green meatballs, cubes, rectangles, and other odd shapes. Overgrown plants have been pruned 12 to 24" from ground and developed new shoots and filled in quite well. Plants have been pruned for over a thousand years. Witnessed a 24" diameter trunk cut to about 3' of the ground with numerous shoots covering the entire surface.

DISEASES AND INSECTS

Needle blight, twig blight, *Phytophthora cinnamomi* root rot, *P. ramorum* on container-grown English Yew in England, other fungus diseases, twig browning, black vine weevil, strawberry root weevil, taxus mealybug, grape mealybug, scales, ants, termites, nematodes, and yew big bud mite on *T. brevifolia*.

PROPAGATION

Although *Taxus cuspidata* 'Capitata' is usually propagated from seed, all other cultivars are propagated by cuttings taken in the late summer through winter and rooted in cold frames and greenhouses. Specific recommendations are listed under *T. canadensis*. Many great recipes in *Proc. Intl. Plant Prop. Soc.* See Dirr and Heuser (2006) for detailed synopsis. With interest in Taxol production, tissue culture has entered the fray and *HortScience* 29(6):695–697 (1994) reported on success with in vitro culture of embryos of *Taxus* species.

LANDSCAPE VALUE

Probably the only negative comment one can apply to yews is that they are overused. The fact that they serve as deer candy is another negative. Their ubiquitous landscape uses make them a favorite choice of designers. They appear, almost to the point of monotony, in hedges, foundations, groupings, broad masses, and as facer plants.

The moderate growth rate, uniform habit, high quality appearance, and maintenance-free aspect result in *Taxus* being classed as the best shrubby, needle type evergreen for landscape use. However, it should be emphasized that *T. baccata*, *T. cuspidata*, and *T. xmedia* can grow 40 to 50' in height. Proper pruning does wonders to keep the plants in bounds.

Taxus baccata L. — English Yew (Common Yew)

(taks'us ba-kā'ta)

LEAVES: Spirally arranged, spreading all around in erect shoots but appearing more or less 2-ranked on horizontal shoots or on plants grown in shade, linear, 1/2 to 1 1/4" long, 1/16 to 1/4" wide, convex and shining dark, almost black-green on the upper surface, with recurved margins and a prominent midrib, paler and yellowish green beneath with ill-defined lines of stomata, gradually tapering at the apex to a horny point.

STEM: Branchlets surrounded at the base by brownish scales, greenish.

SIZE: 30 to 60' high by 15 to 25' spread; 50' plant at Hillier, 1999; magnificent old plant at Tintinhull; usually smaller; tremendous number of clones all varying in size and shape; large plants up to 85' high and 8 1/4' in girth have been recorded.

HARDINESS: Zone (5)6 to 7; hardiness dependant on genotype with 'Repandens' one of the hardiest.

HABIT: Tree or shrub-like, wide-spreading and densely branched; broad-rounded, or shrubby; indescribably beautiful in the best forms with a dense, dark, somber pyramidal outline and often a massive, fluted, rich reddish brown trunk; I have seen nothing in the States to match the splendid old trees in England; often church yards house the most magnificent specimens; the many cultivars offer a multitude of shapes from wide-spreading to distinctly columnar; wonderful collection at Bedgebury Pinetum, Kent.

RATE: Slow.

TEXTURE: Medium.

BARK: Reddish brown, furrowed, thin, scaly, flaky; often fluted on old trunks.

LEAF COLOR: Dark green and lustrous above.

FLOWERS: Usually dioecious, male strobili stalked, globose, arising from the axils of the leaves on the undersides of the branchlets of the previous year, each consisting of 6 to 14 stamens with short filaments; female strobili solitary, green, from the leaf axils, usually opening in March–April.

FRUIT: Seeds solitary, bi-, seldom tri-, or quadrangular, slightly compressed, 1/4" long, 1/5" broad, olive-brown; aril roundish, red.

CULTURE: Does well on calcareous soils as well as acid soils; prefers a moist, well-drained, sandy loam; see under culture in the introductory remarks; sun or shade, in fact, extraordinary shade adaptability.

DISEASES AND INSECTS: *Taxus* mealybug, black vine weevil, *Taxus* scale, yew-gall midge.

LANDSCAPE VALUE: Useful in gardens and parks, in shade, for undergrowth, hedges, screens and foundation plantings; used extensively for topiary work in England; not outstandingly hardy in Zone 5 and inferior to *T. xmedia* and *T. cuspidata* types for that reason.

CULTIVARS: Den Ouden and Boom list over 100 cultivars of this species. Hillier, 2002, describes 31 cultivars. RHS Plant Finder 2008–2009 lists 51 cultivars as commercially available. Bitner (2007) describes 19 cultivars. Apparently cultivated in England for over 1000 years and numerous selections have been made. The following might be considered among the best.

'Adpressa'—Wide-spreading, dense habit; dark green needles only 1/4 to 1/2" long, 1/10" wide, abruptly pointed at apex; will make a large shrub or small tree; plants as large as 30' high are known; female; several 'Adpressa' variations are known including: 'Aurea', 'Erecta', 'Pyramidalis', and 'Variegata'.

'Adpressa Fowle' (Midget Boxleaf English Yew)—Handsome, compact form rather stiffly branched but clothed with short, heavy-textured, lustrous black green needles; grows slowly; introduced by Weston Nurseries, Hopkinton, MA; original plant 7 1/2' high and 16' wide.

Aurea Group (f. *aurea* Carr.)—Several different yellow-foliaged types are included here; the few I have seen are golden in the new growth which eventually fades to green; 'Elegantissima' and 'Summergold', the latter low-growing, broad-spreading, belong here.

'Cheshuntensis'—Narrow columnar with small blue-green needles; faster and hardier than the Irish Yew; female; listed in 1988 Weston Nurseries catalog, not in 1989; raised from seed of 'Fastigiata' by R. Paul, Chestnut, England about 1857.

'Dovastoniana'—Tree form (may be shrub-like), usually short-trunked, widely spreading branches, pendulous branchlets, blackish green needles; apparently becomes immense with age for the original plant measured in 1929 was 56' wide and 12' in trunk circumference; a male but on occasion a branch produces seeds, have seen reference to this as a female; handsome specimen at Edinburgh Botanic Garden; 'Dovastonii Aurea' with yellow shoot tips is known, male.

'Fastigiata' ('Stricta') (Irish Yew)—This is one of the most fascinating of all yews and certainly one of the most common especially in European countries; it is fastigate with all branches rigidly upright; needles blackish green above, streaked with dull green and a narrow shining midrib beneath; generally 15 to 30' high, 4 to 8' wide; have seen it used at Filoli Gardens, California where it is a fine biological accent to the formal architecture of the house; it is a female but male flowers may occur on isolated branches; several cultivars have been raised from seed of this form; 'Fastigiata' occurred (was discovered) sometime around 1780 in Ireland.

'Fastigiata Aurea' ('Stricta Aurea')—Similar in habit but with golden foliage on the young shoots of the season; several selections have been made.

'Lutea' ('Fructuluteo', 'Xanthocarpa')—Arils are yellow-red, otherwise similar to the species; first noted about 1817.

'Nana'—Dwarf form not exceeding 3'; pyramidal; needles smaller and darker green than species.

'Pygmaea'—Dwarf form to 15" high, wide, dense habit; needles less than 1/2" long, radially arranged.

'Repandens'—Dwarf, wide-spreading form with the tips of the branches pendulous; sickle-shaped needles shining dark green above, dull green below; probably the hardiest form of English Yew (Zone 5); widely used in the United States with some of the finest plants located at Longwood Gardens; may grow 2 to 4'(6') high and 12 to 15' across; I have seen plants considerably larger than this; excellent landscape plant; known before 1887; female.

'Standishii'—Somewhat similar to Irish Yew but slower growing and smaller in size; needles yellow, crowded; considered the best golden yew for small gardens; female.

'Summergold'—Foliage predominantly golden in summer, even in sun; semi-prostrate habit; raised from seed in Holland; looks like a golden 'Repandens'; see comment under Aurea Group.

'Washingtonii'—Open, loose form; branchlets yellowish green, leaves tinted a rich gold, finally yellow-green; female; wide-spreading form, 5 to 6' high.

PROPAGATION: Most clonal selections of yews are propagated by cuttings, which root easily but slowly. Seedling propagation is little used, owing to the variation appearing in the progeny, the complicated seed dormancy conditions, and the slow growth of the seedlings. Polish work showed that seeds collected between August 20 to September 10, aril removed, stored at 41 to 47°F for an entire season germinated the best. Side or side-veneer grafting is practiced for those few cultivars which are especially difficult to start by cuttings.

ADDITIONAL NOTES: Yews are among the most toxic of plants. They appear to be poisonous all seasons of the year. The toxic principal is taxine. Foliage, bark, or seeds, whether dry or green, are toxic to people and to all classes of livestock. The fleshy red arils are not poisonous as the toxic principal is contained in the hard part of the seed. This is not digested and is passed so no harm is done. I had a veterinarian in one of my off-campus courses and while discussing yews he mentioned he had seen cows who had died from eating yew foliage and the amount removed from their stomach was very small in relation to their total body weight.

Yew has received notoriety as a source of taxol, a chemical used to treat ovarian cancer. Initially, the bark of the West Coast species, *Taxus brevifolia* Nutt., Pacific Yew, was utilized as the source. *American Forests* 102(3):28 (1996) discusses Pacific Yew and its emergence as a poster child for the conservation of biodiversity. The message is that every plant, no matter how seemingly insignificant, may hold the cure for one of the world's significant diseases. The national champion *T. brevifolia* is 54' high by 30' wide in Mineral, WA. Foliage of *Taxus* species also produces the chemical and there is variation in concentration among cultivars with 'Nigra' and 'Hicksii' among the highest. See *J. Environ. Hort.* 10(4):187–191 (1992) for concentrations of taxol from the leaves of 14 *Taxus* taxa.

Yew is among the most ancient of trees with estimates of Scottish and English specimens in the 3,000- to possibly greater than 4,000-year-old range. A 4,000-year-old tree was discovered in a churchyard in Llangernyw, Wales. The tree's circumference was 47'. At Dundonnell, Scotland in the garden of the late Mr. Alan Rogers, I experienced a plus 3,000-year-old *T. baccata*. Our garden tour group huddled under its magnificent canopy on that bright sunny day in the West Highlands. For a brief moment one could imagine the gathering of the clans, the wailing of the bag pipes, and the call to battle. Actually sounds like a typical tour, only the call was, "Load the coach!"

Good article in *J. Arnold Arboretum* 71:69–91 (1990) that treats the genera of Taxaceae in the southeastern United States. *Torreya taxifolia*, *Taxus canadensis*, and *T. floridana* are discussed.

NATIVE HABITAT: Europe, northern Africa, southwestern Asia. Cultivated since ancient times.

Taxus canadensis Marsh. — Canadian Yew

(taks'us kan-a-den'sis)

LEAVES: Densely set, in 2 ranks, 1/2 to 3/4" long, 1/16 to 1/12" wide, apex abruptly short-pointed, with a slightly raised midrib above and below, glossy dark green above, paler green beneath, needles with 2 blue-green stomatal bands below, assuming a reddish tint in winter, short-stalked.

SIZE: 3 to 6' high by 6 to 8' broad, often twice as wide as high at maturity.

HARDINESS: Zone 2 to 6.

HABIT: Often prostrate, loose, straggling; leaders prostrate and rooting in the ground; very straggly shrub compared to other yew types.

RATE: Slow.

TEXTURE: Medium.

LEAF COLOR: Glossy dark green assuming a reddish tint in winter, almost reddish brown not unlike the worst Andorra juniper color.

FLOWERS: Self fertility occurs in this species; also monoecious, as bagging studies showed both male and female stobiles present with 99% of male on current growth, greater than 33% of female on two year or older, see *Bulletin Torrey Botanical Club* 120(2):115–120 (1993); also, additional discussion of monoecy in same journal 123(1):7–15 (1996).

FRUIT: Seeds broader than high; aril light red.

CULTURE: Transplant balled-and-burlapped; moist, sandy loam; will not tolerate heat and drought; requires winter shade, actually best green color in shade.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Suitable as a ground cover but only for underplanting in cool, shaded situations; the hardiest of the yews; probably the least desirable of the yews for landscape purposes.

CULTIVARS:

‘Stricta’ (‘Pyramidalis’)—Branches stiffly upright yet the plant is wider than high at maturity; bronze-red-purple in winter.

PROPAGATION: Yew seeds are slow to germinate, natural germination not taking place until the second year. Seeds have a strong but variable dormancy that can be broken by warm plus cold stratification. One recommendation is to hold the seeds for 90 to 120 days at 60°F followed by 60 to 120 days at 36 to 41°F. Another recommendation specifies prechilling the seed for 270 days at 36 to 41°F. Vrablic and Shugert, *Proc. Intl. Plant Prop. Soc.* 43:467–468 (1993) discusses sexual propagation (seed) of *T. c.* ‘Capitata’. Their summary reads as follows:

- seed shipped direct from Japan.
- seed stratified for 12 months in sand, outside.
- seed sown, ground beds, in poly houses covered from November to May, saran covered June to October, held for 3 years (3-0).
- seedlings transplanted for 3 years (3-3).
- transplants to the field for 4 to 7 years (10 to 13 years from seed).
- no top pruning as a seedling or transplant, field-grown plants pruned by hand annually during the first 2 weeks of August.

Most yews root readily from cuttings and the recommended practice is to procure wood from October through January. The cuttings are treated with a hormone dip or powder (IBA, 5,000 to 10,000 ppm talc or quick dip) and placed in sand or sand:peat. Misting is used although I have placed flats of yew cuttings under the bench, watering them only when other plants needed water and had excellent success. Rooting time is rather long and 2 to 3 months would probably represent an average time span from sticking to rooting.

NATIVE HABITAT: Newfoundland to Virginia, Tennessee, Iowa and Manitoba. Introduced 1800. I have found it growing out of sandstone cliffs in deep shade in Turkey Run State Park, Marshall, Indiana. In the Midwest, this is probably its southernmost location.

Taxus cuspidata Sieb. & Zucc. — Japanese Yew

(taks'us kus-pi-dā'ta)

LEAVES: Short-stalked, mostly not distinctly 2-ranked, upright and irregularly V-shaped, straight or slightly curved, slightly leathery, apex rather abruptly sharp-pointed, 1/2 to 1" long, 1/12 to 1/8" wide, dull to dark lustrous green above, paler beneath with 2 yellowish green bands.

BUDS: Ovoid-oblong, chestnut brown, composed of overlapping, concave, ovate scales more or less keeled on the back.

SEEDS: Ovoid, about 1/3" long, hard, aril red.

SIZE: 10 to 40' with an equal or greater spread; usually smaller depending on cultivar; see cultivar list for specifics; in native haunts it may grow 40 to 50' high.

HARDINESS: Zone 4 to 7; the hardiest and most adaptable species for the upper Midwest.

HABIT: Crown erect or flattened, broad or narrow, of irregular habit and spreading or upright-spreading branches; can be grown as a tree or multi-stemmed shrub.

RATE: Slow.

TEXTURE: Medium.

BARK: On old tree-like specimens is a handsome reddish brown, exfoliating in scales or longer strips.

LEAF COLOR: Dark lustrous green above, yellowish green beneath.

FLOWERS: Dioecious, see *T. baccata* for description.

FRUIT: Seeds ovoid, about 1/3" long by 1/6" broad, compressed, aril red.

CULTURE: Transplants well balled-and-burlapped; the roots of the yews are rather thick but abundant and a large mass of roots is normally present around the base of young plants which allows for successful transplanting; prefers a moist, sandy loam although adaptable, must be well-drained; shade or sun; superior to other conifers in shade; sun and wind may cause needles to turn yellowish brown; furthermore, it endures the dust and smoke of city atmospheres surprisingly well and withstands any amount of pruning.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Excellent for many purposes: foundation plantings, hedges, topiary, screens, bonsai, masses, groupings, bank covers.

CULTIVARS:

'Aurescens'—Low, compact, slow-growing form, 1' by 3'; may reach 3' high at maturity; leaves of the current year's growth deep yellow, changing gradually to green; male.

'Capitata'—Usually a pyramidal form, can be maintained in a tightly pruned form, however, will grow 40 to 50'; a common form in cultivation and certainly a functional landscape plant.

Captain™—Uniform, fast-growing; clone of 'Capitata' with improved winter foliage color; Studebaker Nursery introduction.

'Cross Spreading'—A form selected by Cross Nurseries, Lakeville, MN that is highly resistant to winter burn; grows 3 to 4' high and 8 to 10' wide.

'Dark Green Spreader'—Compact habit, spreading, 4 to 5' high, 6 to 8' wide; dark green needles; supposedly hardier and with less foliage discoloration in winter; maybe a *T. ×media* type.

'Densa'—Low shrub form, two times as broad as tall with extremely dark green leaves; 40-year-old specimen is 4' by 8'; female; one of the best dwarf forms.

Emerald Spreader™ ('Monloo', PP 10,335)—Low, flat-topped, wide-spreading habit, 30" by 10' in 20 years; lustrous dark green needles; some red-ariled seeds are produced; considered hardier than *Taxus baccata* 'Repandens', to Zone 4; handsome form with soft foliage presence; observed plants in Raleigh, NC area that, when installed in heavy soils, declined rapidly.

'Expansa'—According to Wyman a name applied to many *Taxus cuspidata* seedlings with a vase-shaped habit; this form has an open center, loose foliage and branches at a 45 to 60° angle from the base; about 1 1/2 to 2 times as broad as high; male and female clones available.

'F. & F. Compacta'—Rounded spreader, 4' by 8 to 9'; offered by Angelica Nurseries, Kennedyville, MD.

Golden Jewel™—New foliage bright gold when emerging, holding with inner needles contrasting green, color is retained through summer; 10 to 15' by 5 to 6'; Klyn Nurseries introduction.

Golden Treasure™—Bright golden needles, best color in sun; spreading habit, 3 to 5' by 5 to 6'; Klyn Nurseries introduction.

'Green Wave' (PP 2,052)—Dark green foliage and low-mounded, spreading habit with distinctive, graceful, arching branches; considered a good substitute for *T. baccata* 'Repandens'; 3 to 4' by 6 to 8'; offered by Angelica Nurseries.

'Intermedia'—Dwarf, round, compact, slow-growing form; leaves densely set; resembles 'Nana' with the same heavy, plump, dark green leaves; starts growth earlier in the season and grows faster.

'Jeffrey's Pyramidal'—Heavy fruiting, pyramidal form.

'Klehm's Spreader'—Spreading habit, 4 to 6' by 6 to 9'; dark green and resistant to winter burning; selected by Roy Klehm in South Barrington, IL; female.

'Nana' (var. *nana* hort. ex Rehder)—Slow-growing form with spreading branches; needles radially arranged; twice as wide as high; excellent fruiting form; in Minnesota has shown some resistance to winter burn; 6 to 8' high plant at Hillier; listed as male.

North Coast™ ('Nocozam')—Low, broad, flat-topped habit, 3 to 4' by 6 to 8'; lustrous dark olive-green needles; selected for winter hardiness (Zone 4) and drought tolerance; Lake County Nursery introduction.

'Pyramidalis'—Pyramidal form with dark green leaves; introduced by Hill's, Dundee, IL.

'Thayerae'—Slow-growing, wide-spreading form (8' high, twice as wide) with branches at a 30° angle with ground and forming a flat-topped head, centers are full; some consider this a *T. ×media* type; raised in Massachusetts around 1916–1917.

'Winston Peters'—Lower, broader, faster growing than 'Densiformis' with lighter shiny green needles; supposedly with excellent root system and quite easy to transplant.

PROPAGATION: Cuttings of most clones will root readily. *Taxus cuspidata* var. *capitata* is often grown from seed as it comes fairly true-to-type. Cuttings from *capitata* should be collected from vertical terminal growth as laterally spreading cuttings will develop into spreading types.

ADDITIONAL NOTES: The new growth on *Taxus* is a lovely soft yellow-green which develops in May and is effective for about one month. The emphasis on well-drained soil cannot be stressed enough. *Taxus* does not tolerate "wet feet" for any period of time. Even if they do not die, the growth is often reduced. About the best advice is to plant high if the soil is hopelessly wet and use raised beds. Pruning can be accomplished about any time but early in the growing season is often recommended. Hard, close pruning is not recommended as this results in the formation of a shell of foliage and a very formal appearance. The best way is to hand prune removing the longest growth every other year and thus creating an "unpruned" effect.

NATIVE HABITAT: Japan, Korea, Manchuria. Introduced 1853.

Taxus ×media Rehd. (*T. cuspidata* × *T. baccata*) — Anglojap Yew

(taks'us mē'di-a)

Similar to *T. cuspidata* in many respects, however, differing in olive color of the branchlets which do not change to brown the second year, the blunt bud scales and the distinct two-ranked leaves.

SIZE: Variable, 2 to 3' high to 20' high; every cultivar is different.

HARDINESS: Zone 4 to 7.

HABIT: Broad-pyramidal, medium-sized large shrub to small tree, of spreading habit often with a central leader.

Actually, it is very difficult to ascertain the exact habit and size of the Anglojap types since they are hybrids and the growth characters they exhibit are variable. I have seen the excellent *Taxus* collection at Wooster, OH, and it is here that growth differences are very evident. The plants have not been pruned and have developed naturally. It is extremely difficult to identify *Taxus* by needle characteristics and when they have been pruned into little squares, balls and hedges in the landscape, there is no hope. Often nurseries sell *Taxus* "spreaders" which could be about anything.

RATE: Slow.

TEXTURE: Medium.

LEAF COLOR: Similar to *T. cuspidata*; dark green, often lustrous above, lighter green beneath.

FLOWERS: Dioecious, see under *T. baccata*.

FRUIT: Fleshy, red aril covers hard, brown seed.

CULTURE: Transplants well balled-and-burlapped; prefers a moist, sandy, acid to neutral loam; must be well-drained; shade or sun.

DISEASES AND INSECTS: See culture sheet.

LANDSCAPE VALUE: Depending on the cultivar, may be used for hedges, screens, foundations, and mass plantings.

CULTIVARS:

'Amherst'—Slow-growing, dense, compact form; 12-year-old specimen is 6' by 9'; male.

'Andersonii'—Spreading type to 4 to 5' high; deep green foliage; excellent winter color; considered Zone 4 hardy.

'Angelica'—A slow, low-growing form, 3 to 4' by 6 to 8'; good dark green needles; considered extremely hardy.

'Anthony Wayne'—Wild columnar form with light green new shoots; 10 to 12' by 8'; relatively fast growing; female; landscape effect is similar to 'Hatfield' but growth is faster; from Hess Nursery, NJ; an old cultivar.

'Beanpole'—Narrow columnar form, dwarf; slow-growing, can reach 8 to 10' high; female; Vermeulen Nursery introduction.

'Berg'—Spreading habit, 4 to 5' by 6 to 9'; dark green needles, non-burning strain; female; selected by Bergman Nursery, Quincy, IL.

'Berryhillii'—A female clone; dense growing spreading type, 20-year-old plant is 5' by 9'; resembles *T. cuspidata* 'Nana'; high resistance to winter burning.

'Bonny Green Mound'—Small, dense globe; extremely tight habit; bright green needles; 3 to 5' by 3 to 5'; listed by the late Roslyn Nursery.

'Brownii'—Male clone with a densely rounded habit; foliage dark green; 9' by 12' after 15 to 20 years; easily pruned and can be maintained at any height; common form in Midwest; have seen it listed as female but have not observed fruit set.

'Chadwickii'—Low-growing, compact spreader with handsome lustrous dark green foliage that holds up well in winter; 2 to 4' by 4 to 6'; named after Dr. L.C. Chadwick, one of my mentors at The Ohio State University.

'Citation'—Compact, bushy upright form, 8 to 10' by 5 to 6'; not unlike an intermediate between 'Hatfieldii' and 'Hicksii'.

'Deerfield'—Broad mound; dark green foliage, does not discolor significantly in winter, leaf out later; supposedly increased heat tolerance and better root system.

'Densiformis'—Dense, shrub-like form, twice as wide as high; needles bright green, first year branchlets greenish brown in winter; 3 to 4' high, 4 to 6' wide; Angelica Nurseries lists this as a female clone.

'Densiformis Imp'—Spreading habit, 3 to 4' by 4 to 8', rapid growing; feathery light green foliage; is this the same as 'Densi-Gem'?

'Densi-Gem'—Spreading form; faster growing than 'Densiformis' with a fluffy fuller appearance; 4 to 6' high.

Erie Shores™ ('Ershzam')—Low-spreading, 2' by 4 to 5'; black-green needles; good winter hardiness, Zone 4; Lake County Nursery introduction.

'Everlow'—A dark green-needed, low-growing spreader; resistant to wind desiccation; may be a good substitute for *T. baccata* 'Repandens' in colder climates; 1 1/2'(3 to 4') by 4 to 5'.

- 'Flemer'—Good dark green needles, color holds well in winter; similar to 'Sebian' but with full center, more dense and compact; female form; 6' by 10' in 20 years.
- 'Flushing'—Slender, narrow columnar, stately form with thickish, lustrous dark green needles and red seeds; grows 12 to 15' high, 3' wide.
- 'Grandifolia'—Only observed in a photo but mid-columnar, extremely uniform, dense, dark green needles.
- 'Halloran'—Broad, compact form; branches erect, sprays erect; leaves densely set, dark green; 6' by 6' in 20 years.
- 'Hatfieldii'—Dense, broad pyramidal form; leaves dark green; 20-year-old plant is 12' by 10'; an excellent clone; predominantly male; I witnessed a 30' high, 20' wide specimen on the grounds of Chateau Sur Mer, Newport, RI; apparently this cultivar was in common use when many of the Newport mansions were being constructed.
- 'Hicksii'—Male and female clones; columnar in habit; needles lustrous dark green above, lighter green beneath; similar to the Irish Yew but more hardy; 20' high after 15 to 20 years; 10 to 12' by 5 to 7'; raised at former Parsons Nursery, Flushing, NY; selected and introduced by Henry Hicks; fairly narrow in youth becoming fatter with age.
- 'Kelsey'—Erect, dense, compact form taller than broad; free-fruited female form; very dark green needles; 20-year-old plant is 12' by 9'.
- 'Kobelli'—Upright spreading to mounded, 4 to 5' by 5 to 6'; dark green needles.
- 'L. C. Bobbink'—Fine-textured, glossy dark green needles, color holds well in winter; globe- to mound-shaped; 6' high, 6 to 8' wide; female.
- Legislator™ ('Leyzam')—Spreading 4' by 8'; dark green needles; Lake County Nursery introduction.
- Margarita™ ('Geers', PP 16,049)—Cool lime green needles, does not burn or turn off color like yellow-needle types; 4 to 5' high; discovered in the Netherlands.
- 'Meadowbrook'—Columnar growth habit and fine needle texture; 4' by 18" in 10 years; found on an estate on Long Island, NY.
- 'Moon'—Upright-rounded habit; branches and shoots ascending; shiny dark green needles, densely arranged; 10 to 12' by 10 to 12'.
- 'Old Westbury'—Handsome form with deep green needle color; narrow upright column; branches tight and compact.
- Representative™ ('Repzam')—Broad-columnar, 10' by 6'; black-green needles year round; Lake County Nursery introduction.
- 'Runyan'—Handsome spreading form 4 to 5' by 6 to 9' with lustrous dark green needles; good winter hardiness; popular in Ohio, lower Midwest; from Spring Grove, Cincinnati.
- 'Sebian'—Straight dark green needles; intermediate compact spreading form with flat top; good winter hardiness (Zone 4); 6' by 12' in 20 years; male.
- Senator™ ('Senzam')—Pyramidal form, 20' by 4 to 5'; glossy dark green needles; Lake County Nursery introduction.
- 'Sentinalis'—Very narrow form; female; 10-year-old plant is 8' by 2'.
- 'Stoveken'—Excellent broad columnar form; densely set dark green needles; male; 20-year-old specimen is 12' by 6'; 20' in 30 years.
- 'Tauntonii' ('Taunton')—Spreading form about 3 to 4' high, 5 to 8' wide; most interesting because it is about the only *T. xmedia* type to show resistance to winter burn in Minnesota; on the other side of the ledger, it is the only *T. xmedia* type performing well in the heat of Zone 7.
- 'Vermeulen'—Slow-growing, rounded type; female; 20-year-old plant is 8' by 9'.
- 'Viridis'—Slow-growing narrow columnar form; foliage lighter green than typical, new growth bright yellow-green, needles twisted; 10 to 12' by 1 to 2'.
- 'Wardii'—Wide-spreading, flat topped, dense form; foliage dark green; female; 20-year-old plant is 6' by 19', range is 5 to 8' by 15 to 20'.

PROPAGATION: Propagate vegetatively (cuttings) to maintain trueness-to-type.

ADDITIONAL NOTES: A hybrid species first raised by T.D. Hatfield of the Hunnewell Pinetum, Wellesley, MA about 1900. Since that time numerous selections have been made and often it is difficult to tell if one is looking at a *T. cuspidata*, *T. baccata*, or *T. xmedia* type. Unfortunately, nurserymen have confounded the issue by indiscriminately naming and introducing clones which they thought were better. When one sees a whole nursery block of a certain yew next to another block, specific differences are noticeable such as foliage color, needle density, and habit, however, once they have been massacred in the landscape by the hedge shears (worst landscape tool ever invented), there is no effective way to distinguish between and among different clones.

"A Study of the Genus *Taxus*" was available from the OARDC, Wooster, OH, as Research Bulletin 1086. The publication contains a wealth of information on the *Taxus* collection at Wooster, early history of yews, the development of the Hatfield yews, morphology, sex and fruiting characteristics, propagation, culture, and an extensive treatment of *Taxus* species, clones, and cultivars. Written by Drs. R.A. Keen and L.C. Chadwick it should prove invaluable for anyone interested in this most important group of landscape evergreens. Anyone interested in hardiness evaluations should consult *Nursery Notes* Vol. II (4), July—

August (1978). The Ohio State University. Drs. Chadwick and Smith performed a genuine service by evaluating the extensive *Taxus* collection after the devastating winters of 1976–77, 77–78.

Certainly could use heat-tolerant yews in Zones 7 and 8 of the Southeast. *T. wallichiana* var. *chinensis* et al. were mentioned in the *Taxus* introduction. The original plant that Dr. Raulston promoted was almost like *T. cuspidata* 'Capitata'. Subsequent plants from cuttings that I and others tested resulted in spreading shrubs. Several 5 to 6' high, 8' wide plants grew in the Georgia trials and were shown to every visitor. I can't remember a single person asking for cuttings. At the Sarah P. Duke Gardens, a 20' by 20' *T. wallichiana* var. *mairei* with dark green needles thrives and impresses. *Taxus floridana* that should offer great heat tolerance has never impressed because of loose habit and foliage discoloration in winter. My thinking is that *Cephalotaxus* times *Taxus* hybrids might be deer resistant and heat tolerant. A promising (?) undertaking for a young plant breeder!

Ternstroemia gymnanthera (Wright & Arn.) Bedd. (usually sold as *Cleyera japonica* Thunb.)

— Japanese Ternstroemia, Japanese Cleyera

(tĕrn-strō'mi-a jim-nan'thĕr-a)

FAMILY: Ternstroemiaceae, also placed in Theaceae; *Cleyera* and *Eurya* follow the same family treatment.

LEAVES: Alternate, simple, evergreen, leathery, narrow-oblong to ovate-oblong, 2 1/2 to 4" long, 1/2 to 1 1/2" wide, bluntly pointed at the apex, narrowly wedged-shaped at the base, entire, glabrous, lustrous deep green above, paler beneath; petioles—about 3/4" long, stout, red or reddish purple in color; leaves appear whorled at end of stem.

SIZE: 8 to 10' high, 5 to 6' wide; may grow 15 to 20' high; can be maintained at a 4 to 6' height indefinitely with proper pruning.

HARDINESS: Zones 7 to 9 and into 10; severely injured at –3°F; many old 10 to 15' high plants on the Georgia campus were killed to the ground; Raulston reported the loss of two 25-year-old specimens after –6 to –8°F in January 1985.

HABIT: Distinctly upright-oval to oval-rounded, densely branched evergreen shrub; may be grown as a small tree but most plants I have seen were shrub-like; open-grown specimens are quite artistic.

RATE: Slow.

TEXTURE: Medium.

LEAF COLOR: Emerging leaves bronze to red, changing to lustrous dark (midnight) green at maturity, and may develop a rich reddish bronze color in winter; leaves tend to be clustered at the end of the branch resulting in a whorled or tufted appearance; considerable variation in new leaf color since plants are most often seed-grown.

FLOWERS: Perfect, 5-petaled, white to yellowish white, 1/2" across, borne 1 to 3 together from the leaf axils on the previous year's wood, or on short spurs, pedicels reflexed, about 1/2" long, petals fleshy, May–June.

FRUIT: Egg-shaped, 1/2" diameter, 1" long, green to red berry that ripens in September.

CULTURE: Container-grown and easily transplanted; prefers moist, well-drained soils; appears to do best in shade or partial shade on east or north side of structures; acceptable in full sun but is prone to greater winter leaf discoloration; responds well to pruning; a pruning study of container-grown plants showed that pruning in late February (Mississippi) produced superior plants; essentially intolerant of wet, poorly drained soils.

DISEASES AND INSECTS: None serious although leaf spot is becoming more prevalent; caused by *Cercospora* species; respectable evaluation paper, *Bulletin* 666, Alabama Agr. Expt. Stat. (2007) evaluated 6 taxa.

LANDSCAPE VALUE: Good accent plant, can be used for screens and hedges; foliage is attractive; best used in shady situations, although sun is acceptable; a group of these plants sited in full sun on the Georgia campus is yellow-green, purple-green, and green in the winter; the plant is grown from seed and variation results; observed seedling blocks in nursery production with every imaginable color to the new growth from green, yellow, gold, bronze to purplish red.

CULTIVARS: Abundant interest in superior selections since the demise of *Photinia* × *fraseri*; Greenleaf Nurseries, Tallequah, OK, Wight Nurseries, Cairo, GA, and PSDI/Flowerwood Nurseries, Loxley, AL have introduced new selections.

Big Foot™ ('Sotall', PP 13,680)—Larger leaves; quite vigorous, upright habit, 6 to 8' by 4 to 8'; tested a plant for several years and though acceptable not that unique from general species; PSDI/Flowerwood introduction; *Cercospora* susceptible.

Bronze Beauty™ ('Conthery', PP 11,735)—New growth beautiful bronze, small leaves; compact habit; PSDI/Flowerwood introduction; *Cercospora* susceptible, significant winter leaf discoloration.

'Burgundy'—Selection that has burgundy new growth, fall and winter color; selected by Tom Dodd, Jr.

'Burnished Gold'—A yellow-gold-bronze foliage form that is bright yellow-gold, almost yellow-bronze, in spring and summer; the foliage color diminishing with the heat of summer; plant habit akin to species; good vigor; introduced by the J.C. Raulston Arboretum.

'Clemson'—Burgundy new growth; good screen; offered by Ted Stephens.

Copper Crown® ('Grewad', PP 10,521)—Possesses a full, self-branching, regular growth habit; burgundy new foliage in spring; burgundy color in new growth is present on any new growth occurring during cool weather; this uniform, self branching variety is an improvement over the irregular growth rate and forms of seedling populations; slight *Cercospora* susceptibility.

'Dodd Littleleaf'—A diminutive leaf form, about 1/4 to 1/3 those of the species; upright habit to 6', relatively dense in branching and foliage; a plant in the Dirr garden was quite content; introduced by Tom Dodd, Jr.; the story goes that Mr. Dodd took seed of *T. gymnanthera* to Emory University and had them irradiated, four seedlings exhibited dwarf characteristics, one with smaller light green leaves and a smattering of variegation was named 'Emory'.

Jade Tiara® ('Grevan', PP 10,522)—An improved selection with compact, uniform growth and full, self-branching habit; leaves are smaller and branching is denser than typical; symmetrical mound of dense semi-glossy foliage.

'Grimes'—Variegated leaf form, introduced by Tom Dodd, Jr., Semmes, AL.

LeAnn™ ('Contherann', PP 11,737)—Upright shrub 10 to 12' by 6 to 7'; orange-red new leaves; PSDI/Flowerwood introduction; highly resistant to *Cercospora*.

'Lynn Lowrey'—A dwarf selection with smaller leaves.

'Phyllis Ann'—Small, deep green leaves; resistant to shot-hole fungus; selected by Jim Scoggins, Wight Nurseries, now a division of Monrovia.

Regal™ ('Conthera', PP 10,811)—Bright red new growth, rich dark green at maturity; 8 to 10' by 6 to 8'; PSDI/Flowerwood introduction; *Cercospora* susceptible.

'Ruby Deluxe'—Compact habit; new growth vivid burgundy; Live Oak Gardens introduction.

Sovereign® ('Greyou')—Full, uniform, self-branching habit; uniformity of growth is the real improvement over the typical seedling populations which are variable in growth and form.

'Variegata' ('Tricolor')—A beautiful but perhaps excessively gaudy cultivar; the dark green leaves are marbled gray and possess a creamy white to yellowish margin that turns to rose-pink with the advent of cold weather; not as vigorous as the species.

PROPAGATION: Cuttings collected late in summer or fall can be rooted; seed collected in fall and planted germinates readily the following spring; seeds are the primary method of propagation; have seen whole nursery blocks in Mobile, AL and the variation was maddening.

ADDITIONAL NOTES: Totally confused in the nursery trade. What is called *Cleyera japonica* is actually *Ternstroemia gymnanthera*. The differences between the two species reside in various minute floral characters. Easiest way to separate is the way leaves are borne: *Ternstroemia*—pseudo-whorls like *Pieris*; *Cleyera*—alternate and widely spaced to end of stem.

NATIVE HABITAT: Japan, Korea, Taiwan, China, India, Borneo.

RELATED SPECIES:

***Cleyera japonica* Thunb. — Japanese Cleyera**
(klē-ēr'a ja-pon'i-ka)

LEAVES: Alternate, simple, evergreen, ovate, 1 to 3" long, 3/4 to 1 1/4" wide, twisted acuminate tip, cuneate, entire, lustrous dark green and glabrous above, veins scarcely evident, dull olive-green and glabrous below; petiole—1/4" long.

BUDS: Terminal—1/2" long, red, twisted, and pointed, 2 visible scales; slight crook; laterals—1/8" long, reddish brown, borne at 45° to stem.

STEM: Green, slender, glabrous, becoming grayish brown with maturity; pith white, solid, small.

Cleyera japonica, Japanese Cleyera, is an upright, broadleaf evergreen shrub or small tree growing 10 to 15' high. The new growth is often bronze or reddish (not to the degree of *Ternstroemia gymnanthera*) maturing to lustrous medium to dark green. Leaves typically do not discolor (stay green)

in full sun during winter. However, three seedling plants in our Chapel Hill garden developed varying shades of red-purple in winter. Plants on the Georgia campus remained green. About 340 miles northeast may be the catalyst for coloration. Might add that leaf spot has occurred in both locations, a red spotting of the foliage, appearing similar to *Entomosporium* infection. The cream-white, perfect flowers occur 1 to 5 in the leaf axils and are followed by globose, indehiscent, shiny black fruit. Although little known and almost totally confused in American horticulture, the plant has possibilities. Hardiness is greater than literature ascribes, at least to Zone 6. It grows in sun or shade. Several variegated cultivars include: 'Fortunei' (listed as *C. fortunei* Hook. f. 'Variegata') with thinner, bright green leaves variegated cream, golden yellow, and rose on margins; and 'Tricolor' with bronze-purple new growth, changing to cream-yellow margins with gray-green center, and in cold weather rose-pink. I have observed both. The latter is louder, although considered the same by Hillier, 2002. 'Fortunei' and 'Tricolor' were offered as different entities in RHS Plant Finder 2008–2009. Caution, wear your sunglasses! Approximately 17 *Cleyera* species are acknowledged with *C. japonica* the only cold hardy, garden worthy form. Native to Japan, Korea, China, Taiwan. Cultivated 1870. Zone 6 to 8(9). Cleaned seeds germinated 3 weeks after sowing. Seedlings were quite uniform, almost appearing apomictic. Plants grow extremely fast and fill a 3-gallon container in a single season. Cuttings, firm, May–July into fall, root easily.

Eurya japonica Thunb., (ū'ri-a ja-pon'i-ka), and ***Eurya emarginata*** (Thunb.) Mak., (ū'ria ē-mār-ji-nā'ta), are the only two representatives of this rather large (about 70 species) genus that I encounter in gardens. The former has larger, handsome, bluntly serrate, lustrous dark green leaves, about 1 1/4 to 3 1/4" long, 1/2 to 1 1/4" wide; 1/4" diameter, white, dioecious, axillary, somewhat odd fragrance flowers as early as late February–early March; flowers occur on lower side of shoots, almost hidden; and 1/5" diameter, purplish black, globose fruits. 'Winter Wine' was introduced by the U.S. National Arboretum. It is smaller, slower growing, more spreading, with burgundy winter foliage. The species can grow to 30' high; typically smaller in the garden, range of 4' by 6'. The latter species is more common (still scarce) with small, 1 to 1 1/2" long, 1/2" wide, lustrous dark green, crenate-serrate, obovate, obtuse to emarginated at apex leaves. Flowers are blackish, malodorous and fruits are 1/5" diameter, glabrous, purple-black, globose. *Eurya emarginata* is at best hardy to Zone 7; *E. japonica* best in Zone 8 and higher. Neither species will make the horticultural hit parade. It has taken me almost a career to learn these two species and I still am tentative about identification. *Eurya emarginata* is native to coastal southern Japan, *E. japonica* to Japan, Korea, Taiwan. Noted a variegated form at Hillier, the leaves with a thin, dark green margin and gray-green center. Ted Stephens offers this as 'Moutiers' (formerly 'Green Thinly Margined'). He also offers 'Meadow Snow' with a tantalizing array of white-splashed leaves.

Eurya japonica

Eurya emarginata

Tetracentron sinense Oliv.

(tet-ra-sen'tron sī-nen'sē)

FAMILY: Tetracentraceae

LEAVES: Alternate, simple, 3 to 5" long, 1/2 to 3/4's as wide, ovate to elliptic-ovate, acuminate, subcordate or rounded, serrulate with obtuse teeth, 5 to 7 palmate veins, new growth bronze, dark green at maturity.

BUDS: Slender, pointed, with 2 outer scales.

STEM: Dark brown, glabrous, with light lenticels.

Tetracentron sinense is a small, round-headed tree not unlike *Cercidiphyllum* in leaf characteristics. It is essentially unknown in eastern gardens and probably best reserved for the Pacific Northwest. Garden size approximates 30', although the species is listed to 100' in the wild. There are worthy specimens at Edinburgh Botanic Garden and Mt. Stewart, Northern Ireland. Bark on the Edinburgh tree was gray-brown, with rounded mosaics. Difficult to describe, once observed, never forgotten. The perfect, yellowish flowers occur in 4 to 6" long spikes in June–July. Fruit is a 4-celled, deeply lobed, dehiscent capsule. Probably best in light shade and a moist, woodland type soil. I acquired several seedlings and, unfortunately, they were not adaptable to Zone 7 heat and drought. Certainly worthy of trial wherever adventuresome gardeners roam. Central and western China. Found on moist slopes and bottomlands. Asian Ambrosia beetle has damaged trees at one nursery in the Atlanta area. Introduced 1901. Zone 6 to 7.

Tetradium daniellii (Benn.) T.G. Hartley (formerly *Euodia daniellii* (Benn.) Hemsl.) — Korean Tetradium
(tet-ra'di-um dan-i-el'ē-ī)

FAMILY: Rutaceae

LEAVES: Opposite, pinnately compound, 9 to 15" long, leaflets (5)7 to 11, ovate to oblong-ovate, 2 to 5" long, acuminate with obtusish point, rounded at base, sometimes broad-cuneate or subcordate, finely crenulate, lustrous dark green above and glabrous, pubescent below on the midrib and in the axils of the veins; petiole—1 1/2 to 2 1/2" long.

BUDS: Solitary, sessile, ovoid, 1 pair of rather indistinct scales, terminal—puberulent, gray-brown; exposed and visible; differing from *Phellodendron* where the buds are hidden by the petiole base.

STEM: Round or somewhat 4-angled or wrinkled; leaf scars—broadly crescent-shaped, low; 3 bundle traces; pith—moderate, somewhat angular, firm, continuous.

SIZE: Will probably grow 25 to 30' high under landscape conditions but can reach 50'; the spread is equal to or greater than the height.

HARDINESS: Zone (4)5 to 8; I have seen specimens at the Morton Arboretum, Lisle, IL, which showed good vigor and abundant fruit; reports from the Morton indicated dieback and decline possibly owing to disease; Cappiello reported tip injury in Orono, ME; Hayman reported 80% dieback at -24°F at Bernheim Arboretum during the January 1994 freeze; also a reasonably thrifty plant on the Georgia campus.

RATE: Medium to fast, especially in youth; seedlings which I grew in containers reached 5 to 6' in a single growing season.

TEXTURE: Medium in leaf and in winter.

BARK: Older stems and branches develop a smooth gray appearance which is interrupted at irregular intervals by raised lenticels; reminds of beech bark.

LEAF COLOR: Lustrous dark green in summer; the foliage is quite free of pests and diseases and looks as good in August as it did when first maturing in May; fall color is of no consequence as the leaves usually drop green or yellowish green.

FLOWERS: Small, white, borne in 4 to 6" broad, flattish corymbs on current season's growth in June, July–August; the flowers are borne in great quantities and provide quite a show when few other plants are in flower; bees love them; in full flower late July, Boston.

FRUIT: Capsule, composed of 4 to 5 carpels which split from the top; red to black in color and effective in late August through November; the fruits are effective from an ornamental standpoint; seeds are lustrous brownish black, about the size of buckshot.

CULTURE: Easy to transplant; seems to prefer a well-drained, moist, fertile soil; pH adaptable; full sun; may be a bit tender when young and should be well-sited and mulched; one authority noted that any soil is acceptable for culturing this plant; has performed reasonably well in the Georgia test plots.

DISEASES AND INSECTS: None of any consequence.

LANDSCAPE VALUE: A very interesting tree, but unfortunately little known and used; a lovely small tree which can be used in the small landscape; excellent summer foliage, flower, and fruit characteristics make this tree worthy of additional use; Wyman noted that the wood is comparatively weak and splits easily and the tree is short-lived (15 to 40 years); I have observed numerous *Tetradiums* throughout the Midwest, East, and South and have not noticed any serious structural problems; this tree might warrant a close look especially for urban areas; old venerable specimens, possibly from Wilson collections, that I suspect are ±100-years-old reside in the Arnold Arboretum.

PROPAGATION: Seeds which were sent from the Morris Arboretum, Philadelphia, PA were direct sowed and germinated almost 100 percent.

NATIVE HABITAT: Northern China, Korea. Introduced by E.H. Wilson in 1905.

RELATED SPECIES:

Tetradium hupehensis, (tet-ra'di-um hū-pe-en'sis), Hupeh Tetradium, formerly *Euodia hupehensis* Dode is closely allied to *T. daniellii* and may be an ecotype. Supposedly it differs in larger stalked leaflets and the longer beak of the fruit, but according to W.J. Bean the characters are not reliable. *Tetradium hupehensis* can grow to 60' and may be slightly less hardy than *T. daniellii*. Native to central China. Introduced 1907. Zone 5 to 8. Current literature merges *T. hupehensis* with *T. daniellii*, the correct name being *Tetradium*

daniellii. I suspect it will take a long time before the new name change is accepted. In fact, few everyday gardeners have heard of *Tetradium*. RHS Plant Finder 2008–2009 uses the Hupehense Group as the taxonomic umbrella.

ADDITIONAL NOTES: The *Tetradiums* are closely allied to *Phellodendron* but differ in the buds which are exposed in the leaf axils rather than covered by the base of the petiole as in *Phellodendron*. The former name *Evodia* is often written *Euodia* and this was the original spelling as rendered by the Forsters who founded the genus in 1776. Nine species are included in the genus but I have only observed the two taxa described herein and can never assert positive identification.

A few final thoughts concerning a rather handsome group of trees. More adaptable than given credit. Large trees at the Arnold provide inspiration and hope. A single seedling in my Georgia test plots grew over 10' in 3 years. No flowers, but it persisted in the intense summer heat.

*Tetradium
hupehensis*
(leaflet)

Teucrium chamaedrys L. — Wall Germander

(tū'kri-um kam-ē'dris)

FAMILY: Lamiaceae

LEAVES: Opposite, simple, evergreen, ovate to oblong-ovate, 1/4 to 1" long, 1/2 as wide, acute, broad-cuneate, serrate or almost lobed, dark green and pubescent on both surfaces.

Teucrium chamaedrys is best classified as an evergreen subshrub of mounded habit growing about 12 to 15" high. The dark green leaves are present throughout the year. The rose-purple flowers (June–September) are borne in whorls of 4 from the axils of the uppermost leaves and form a 2 to 5" long raceme. They are reasonably showy but are not the principal reason for growing the plant. The species is best used as edging material or a low hedge. It also fits nicely into a rock garden. I have grown the species in Illinois and Georgia with mixed success. In Urbana, IL the extreme cold killed it to the snowline but it did come back. In Georgia it performed more satisfactorily. Easily rooted from softwood cuttings in June provided there is not excessive moisture. 'Nanum' supposedly grows only 8" high or less, spreads 2 to 3', and flowers heavily. 'Variegatum' with cream-colored leaves is known. 'Rose Carpet' and 'Summer Sunshine' are listed. Central and southern Europe, northern Africa, western Asia. Cultivated 1750. Zone 5 to 8(9).

RELATED SPECIES

***Teucrium fruticans* L.**, (tū'kri-um frū'ti-kanz), Shrubby Germander, was first introduced to me in a hotel garden near Blarney Castle, Ireland. The leaves and stems with white tomentum and pale blue flowers in terminal racemes made for an exquisite sight. Although beautiful, I thought it a humidity meltdown candidate in the Southeast. However, a 3 1/2' by 5' plant has thrived in the University's Botanic Garden for many years. Requires sun and well-drained soil. Keep the fertility minimal. Might make a choice container plant. Zone 7, 8 to 10 on West Coast. Southern Europe, North Africa. Introduced 1714.

Thuja L. — Arborvitae

FAMILY: Cupressaceae

The genus *Thuja* constitutes a major group of small to medium (some large) size evergreens used extensively in landscape plantings, especially in the Midwest, East and West. Many cultivars of different form, size, and with varied foliage color are available. Five species in cultivation are native in North America and Eastern Asia. *Thuja orientalis* (*Platyclusus orientalis*) is the least hardy (not totally accurate) of the species and is used extensively in the Southeast, Southwest and West. Some cultivars of *T. occidentalis* are of good quality, however, many types have a tendency to discolor in the winter, with center foliage browning in the fall. *Thuja plicata* and *T. standishii* have the best foliage characteristics of the species. *Thuja koraiensis* is not common in cultivation, but had proven hardy in the lower Midwest and adaptable in Zone 7. *Thuja occidentalis* and *T. plicata* are important timber trees, the wood being used extensively for shingles, shakes, siding, and poles. Some indication that *T. plicata* and hybrids with *T. occidentalis* and *T. standishii* may prove excellent for South, Midwest, and East, as well as West. Arborvitae are not considered to be of the highest quality because of winter discoloration, loss of foliage, and a thin and "ratty" appearance with age. Because of this, many types tend to decrease rather than increase in value, especially in congested planting sites. *Thuja occidentalis* cultivars 'Emerald' ('Smaragd'), 'Nigra', and 'Techny' are very valuable for they maintain good green foliage color in all seasons. The hybrid 'Green Giant' has become a popular choice in recent years. Many new forms in the marketplace; this edition treats 27 new cultivars not included in the 1997 edition.

MORPHOLOGICAL CHARACTERISTICS

Evergreen small trees and shrubs with thin, scaly bark and spreading or erect branches. Juvenile leaves are needle-like and the mature foliage scale-like and imbricate in four rows with glands sometimes on the back. The lateral leaves nearly cover the facial ones with branchlets flattened in one plane. Flowers are monoecious with male types yellow and female types rounded and forming a rounded cone. Cones solitary, ovoid or oblong; scales 8 to 12, with a thickened apical ridge or process, the 2 or 3 middle pairs fertile; seeds 2 to 3 beneath each scale, thick, wing broad or thick, or seeds wingless; cotyledons 2.

GROWTH CHARACTERISTICS

Arborvitae are usually dense, pyramidal trees but vary from narrow- to broad-pyramidal. Numerous cultivars have been selected from *T. occidentalis*, *T. orientalis*, and *T. plicata* and many are available in the trade. Cultivars range from dwarf, round, globe, to narrow-upright types with foliage colors of yellow, bluish, and various shades of green. *American Conifer Society Journal* 14(4):146–151 (1997) reported 105 cultivars of *T. occidentalis*, 36 of *T. orientalis* and 17 of *T. plicata*. I know these numbers are low and in *Nursery Management and Production* 14(4):14–15, 71–73 (1998) I describe 36 cultivars of *T. plicata*.

CULTURE

Arborvitae should be planted in fertile, moist, well-drained soils, although in the wild the species may be found on wet and dry soils; however, maximum growth is not realized on these sites. They are easily transplanted balled-and-burlapped or as container grown plants about any time of year. Arborvitae perform best in full sun, although light shade is acceptable. In heavy shade plants become loose, open, and lose their dense constitution. *Thuja plicata* appears more shade tolerant than *T. occidentalis* or *T. orientalis*. The characteristic winter browning of *T. occidentalis* and cultivars results in an unsightly plant. *Thuja orientalis* also suffers from low temperature stresses and probably should be avoided in Zone 5 gardens although it is frequently offered. Pruning can be accomplished prior to growth in the spring and in summer. Usually extensive pruning is not necessary and if heavy pruning is practiced the result is similar to that achieved with tightly pruned yews.

DISEASES AND INSECTS

Leaf blight, juniper blight caused by *Phomopsis*, *Cercospora*, and *Kabatina*, tip blight, canker (*Seiridium* spp.), arborvitae aphid, cedar tree canker, arborvitae leaf miner, mealybug, scales, bagworms, spider mites, Northern cedar bark beetle.

Physiological Diseases:

Leaf browning and shedding—inner leaves may drop in the fall.

Winter browning—caused by rapid temperature changes, desiccation of needles caused by sun and wind.

Deicing salt injury—primarily from spray along highways; symptoms include browning of foliage on side toward highway as well as stunted growth.

In general, arborvitae exhibit few serious insect and disease problems.

PROPAGATION

Seeds do not usually require a stratification period although selected seed lots have exhibited dormancy. I germinated a large population of seedlings of *T. orientalis* by simply sowing after collection. Stratification in a moist medium at 34 to 41°F for 40 to 60 days will stimulate prompt germination. Cuttings are taken in late summer through early winter. See specific recommendations under the species descriptions. Cultivars are also rooted from cuttings. Our standard procedure is December through March cuttings, 3,000 to 5,000 ppm KIBA, 3 perlite:1 peat, mist, 70°F bottom heat with superlative results. Cuttings can be rooted anytime the wood is firm. Cold stimulates faster, more uniform rooting, hence the logic in winter cuttings.

LANDSCAPE USE

Arborvitae have received wide acceptance in landscaping and are commonly used in foundations and as screens, windbreaks, groupings, accent plants, or hedges. They make excellent tall hedges and screens and, to a degree, have become stereotyped in these roles. The yellow-foliaged forms should be used with discretion for they detract from surrounding plantings. Arborvitae will always be popular landscape plants but some of the new cultivars should be used in preference to seedling-grown material and rag-tag older cultivars.

Thuja occidentalis L. — Eastern Arborvitae, American Arborvitae, White Cedar

(thū'ya ok-si-den-tā'lis)

LEAVES: Scale-like, about 1/12" long, abruptly pointed, those on the main axis conspicuously glandular; on the branchlets sometimes inconspicuously so, bright green above, pale green below, emitting a tansy-like odor when bruised.

BRANCHLETS: Alternate, compressed, flat; sprays horizontal, laterally compressed; 3 to 4 times divided.

CONES: Oblong, 1/3 to 1/2" long, yellowish and erect when young, brown and pendent when mature at the end of the first summer, scales 8 to 10, usually 4 fertile, with a minute mucro at apex; differs from *T. orientalis* which has a distinct spine-like hook on the back of each cone scale near the apex.

SIZE: 40 to 60' high, usually less, by 10 to 15' spread; realistically under cultivation 20 to 30' is more accurate; national champion is 76' by 42' in Alleghany, VA.

HARDINESS: Zone 3 to 7, but not vigorous in the South.

HABIT: A dense, often broad-pyramidal tree with short, ascending branches to the ground which end in flat, spreading, horizontal sprays; usually there is one trunk but multiple trunks do occur; this is a good feature for separating this species from *T. orientalis* which develops many leaders and takes on a more dense, bushy appearance with the sprays borne in strong, vertical planes.

RATE: Slow to medium.

TEXTURE: Medium-fine.

BARK: Grayish brown to reddish brown; the native stands I examined were grayish brown, 1/4 to 1/3" thick, fibrous, forming a more or less close network of connecting ridges and shallow furrows, grayish on the surface.

LEAF COLOR: Flat bright green in summer changing to yellow-brown-green in winter, at times terrifically ugly in winter.

FLOWERS: Monoecious, terminal, solitary.

FRUIT: Cones oblong, 1/3 to 1/2" long, light brown; scales 8 to 10, usually 4 fertile, with a minute mucro at apex; seeds 1/8" long, compressed; wing round the seed, narrow, emarginate.

CULTURE: Readily transplanted from containers or balled-and-burlapped if root pruned; should be grown in areas with considerable atmospheric moisture as well as soil moisture; requires a deep, well-drained soil; thrives in marshy loam; observed plants growing in the Orono Bog, more on hummocks rather than in standing water, 1,600-year-old plant grew in limestone formations in Natural Bridge, VA; full sun; tolerant of pruning; susceptible to strong wind, snow, or ice damage; very tolerant of limestone soils; in spite of the absolute admonitions about this species and the cultivars, it will, once established, take considerable heat and drought; all over Cadillac Mountain, Maine, growing in rock crevices and exposed outcrops; large trees in the limestone soils of Natural Bridge, VA, in the cooler ravines.

DISEASES AND INSECTS: Subject to bagworm, heart rot, leaf miner, spider mites, and deer browsing; see culture sheet.

LANDSCAPE VALUE: Useful as a specimen or accent, good for hedges, shelter-belts, and commonly used as a foundation plant; at times over-used in landscape plantings; 'Emerald', 'Nigra', and 'Techny' are excellent for cold climates; many Februaries past, Dr. Harold Pellett, University of Minnesota, and I were walking around the Minnesota Landscape Arboretum, near the visitor's center, surrounded by snow, were several Techny arborvitae that were still a good dark green color even with the reflected light from the snow, wind, and cold; interestingly, on the ride from the Minnesota airport I was thinking how ugly the yellow-brown arborvitae looked in many of the home landscapes; moral: plant the superior cultivars. Want to re-emphasize the tremendous susceptibility to deer browsing.

CULTIVARS: Many, and I become confused trying to separate the various forms. I suspect there are 80 to 100 cultivars, some of worth, about 90% deserving of trash heap status. *American Conifer Society Journal* 14(4):146–151 (1997) reported 105 cultivars; Hillier, 2002, listed 40 cultivars. I used the literature, nursery catalogs and my eyes in assembling this list. I counted 28 yellow, cream, or otherwise variegated cultivars in van Gelderen and van Hoey Smith's *Conifers*. Bitner (2007) describes and/or illustrates 86 cultivars in *Conifers for Gardens*. RHS Plant Finder 2008–2009 lists 59 that are commercially available. Many of the smaller forms are collector's items or suitable for small-scale landscapes or rock garden situations. Occasionally, I read the literature and see mention of shade tolerance. I don't believe it for a minute and neither does the plant for with time this species becomes thin, open, and generally ratty. Allen Coombes, Hillier, showed me a hybrid between *T. occidentalis* and *T. plicata* 'Aurea Spicata'.

'Aurea'—Broad conical shrub with golden yellow leaves; 2 1/2 to 3' by 2 1/2 to 3'.

'Boisbrained'—Dark green foliage; compact elliptical habit to 10'; listed as winter "burn" resistant; from W.H. Perron, Canada.

'Boothii'—Dwarf, globular, dense; foliage bright green; broader than tall, flat-topped at maturity; 6 to 10' high; named in 1874.

'Brabant'—Spire-like growth; medium green foliage; more resistant to winter discoloration; supposedly quite shade tolerant; 12 to 15'.

'Brandon'—Soft green foliage; resistant to winter burn; narrow cone, 12 to 15'.

'Canadian Green'—Good globose-rounded form with better bright green foliage color than the old standard 'Woodwardii'; listed as 3' high; Zone 3.

'Chalet'—Lime green foliage; similar to Techny; from W.H. Perron.

'Columbia'—Slender column, 15 to 30' high; silver-white variegated tips to the light green leaves, becomes more pronounced in cold weather.

- 'Congabe' (PP 19,009)—Branch sport of 'Rheingold' with red-tipped foliage coloration when grown in full sun, rounded growth habit; discovered by Gabriel Cesarini in Denton, MD; possibly will be given a trade name as the plant was assigned to Conard-Pyle.
- 'Danica'—Dwarf form, 1 to 1 1/2' high; glossy emerald green foliage; has been likened to a dwarf 'Emerald'; from A.R. Jensen, Denmark.
- 'Degroot's Spire'—Narrow columnar form with rich green, twisted foliage like 'Spiralis'; bronzes in cold weather; 6 to 12' by 3 to 5'.
- 'Douglasii Aurea'—Pyramidal, slender, 30 to 45' tall, branchlets spreading; sprays yellow, grading to yellowish green at base; leaves golden yellow, bronzed in winter; developed by D. Hill Nursery Co., Dundee, IL before 1923.
- 'Elegantissima'—Narrow pyramidal form, broadening with age, with dark green foliage that is tipped yellow which turns bronze during winter; 10 to 15' high, 4 to 5' wide; old cultivar.
- 'Ellwangeriana'—Juvenile form; conical, sometimes broad-pyramidal; 6 to 9' tall; leaves on developed branches and branchlets scale-like, other leaves linear, spreading, acicular; a golden needled, slow-growing form is known ('Ellwangeriana Aurea').
- 'Emerald' ('Smaragd')—Saw many years past at Iseli Nursery, Boring, OR and realized it had potential; many nurserymen are growing it; narrow compact pyramidal form; 10 to 15' by 3 to 4', 20' by 3' plant at Hillier in 2006; bright lustrous emerald green foliage in more or less vertical sprays, does not discolor in winter like many forms; also displays excellent heat tolerance; cold hardy to at least -40°F; introduced in 1950; from Poulsen, Denmark; there is also a gold-marked variegated sport of 'Emerald'.
- 'Ericoides'—Juvenile form; dwarf, compact, rounded; 3' tall and wide; leaves linear, spreading in pairs, flat, apex sharp-pointed, yellowish green in summer, brownish in winter.
- 'Filiformis'—Weeping habit to the dense branches that hold loose tufts of long, thread-like, drooping branchlets, new growth bright green, changing to dark green; 6' by 3 1/2'.
- 'Globosa'—Dwarf, globular; 4.5 to 6' high and wide; leaves green, slightly grayish green in winter.
- 'Golden Globe'—Golden yellow foliage; broad globe-shaped habit; supposedly non-burning; sport of 'Woodwardii'; 2 to 3' high and wide.
- 'Golden Tuffet'—Mounded habit, 4' by 6'; golden orange thread-like foliage.
- Goldy™ ('4EVER', PP 19,267)—Upright habit, light green leaves that turn yellow below 41°F, sheds few leaves; sport of *T. plicata* 'Martin' discovered in Netherlands in 2002.
- 'Hetz Midget'—A dense, globe-shaped form that doubtfully will ever grow more than 3 to 4' high; it has a fine rich green foliage and is quite an attractive selection; originated about 1928 as a chance seedling at Fairview Nurseries.
- 'Hetz Wintergreen'—See 'Wintergreen'.
- 'Holmstrup'—Compact, slow-growing, narrow pyramidal form with bright green, tight, bunchy, vertically arranged foliage; holds good foliage color in winter in Georgia; 5' by 2', eventually to 10' high; good for low hedges; have seen abundant cones on relatively young plants; has performed well in the University's Botanical Garden trials; introduced by A.M. Jensen, Holmstrup, Denmark; there is a yellow-foliaged sport, 'Holmstrup Yellow', that appeared to withstand the Zone 7 heat and was bright golden yellow on March 9, 2007 at the Raulston.
- 'Linesville'—A compact dwarfish globe, 2 to 3' high and wide; sage-green needles.
- 'Little Gem'—Dwarf, globose, dense form; broader than tall, 3' high and 4.5 to 6' in diameter; leaves dark green, slightly brown in winter.
- 'Little Giant'—Slow-growing, globe-shaped, small form (1 1/2 to 2' by 1 1/2 to 2') with rich green foliage.
- 'Lutea'—Pyramidal, narrow, 30 to 36' high; sprays and leaves golden yellow, light yellowish green on underside of branchlets; old name was 'George Peabody'; developed before 1873 in Geneva, NY; still one of the best yellow forms.
- 'Malonyana'—Quite a remarkable telephone pole, first observed at Apple Court in Hampshire; dense dark green foliage; columnar, eye-stopping rigidity; cuttings were collected by Mark Griffith and it is in production in the United States; do not know ultimate size as have observed only 10 to 12' high plants; literature states 30 to 40'; to 60' according to Bitner.
- 'Micky' ('Micki')—Narrow conical, slow-growing, 2 1/2 to 3'; fine-textured dark green adult foliage.
- Mr. Bowling Ball® ('Bobazam')—Soft, finely-textured, sage-green needles are feathery in texture; 2 to 3' by 2 to 3'; Lake County Nursery introduction.
- 'Nigra'—Pyramidal form with good dark green foliage persisting through the winter; 20 to 30' high, 4 to 5' wide, possible to 10' wide.
- 'Ohlendorffii' ('Ohlendorffii')—Juvenile foliage form; broad-mounded habit; 2 to 3' by 4'.
- Patriot™ ('KLMeighteen')—Upright, uniform habit; 20' by 5'; medium green winter color; Roy Klehm selection.
- 'Pendula'—An attractive small pyramidal form with rather open ascending-arching branches and pendulous branchlets; a first class plant for accent use; ±15' high; requires staking; held green color at Sarah P. Duke as witnessed on February 17, 2005; developed before 1862 in the Standish Nursery, England.

- 'Pygmy Globe'—Dwarf, globe-shaped form; bright green foliage; 2 to 4' by 2 to 4'; listed by Bailey Nurseries.
- 'Pyramidalis'—Narrow pyramidal, formal in outline with bright green, soft-textured foliage, susceptible to winter burn; 20 to 30' by 5 to 8'; a catchall term?
- 'Rheingold'—A slow-growing, ovoid or conical shrub; 4 to 5' high by 3 to 4' wide; the foliage primarily adult and rich deep gold; it is quite similar to 'Ellwangeriana Aurea' except smaller in stature; no doubt propagated from the juvenile shoots of that form; turns copper to brownish yellow in winter.
- 'Rosenthalii'—Pyramidal, compact, slow-growing; 9 to 15' high, 2 to 3' wide; leaves shining dark green; good hedge form; one reference said no more than 6 to 9' in 50 years.
- 'Sherwood Forest'—According to Raulston, a variegated form, light green with cream-white markings in summer, golden markings in winter; vigorous and fast-growing, to 10'.
- 'Sherwood Moss'—Dwarf, cone-shaped; green juvenile foliage bronzing in winter; 4 to 6' high.
- 'Snowtip'—Dark green foliage with cream-white tips; best color in late summer–fall; pyramidal habit, 8 to 10' by 3 to 4'.
- 'Spiralis'—Narrow pyramidal, slender, 30 to 45' high; branches short; branchlets spirally arranged; sprays somewhat fernleaf-shaped; leaves dark green.
- 'Sudworth Pumila'—Irregular outline with green, gold-tipped foliage, quite similar to 'Lutea'; has performed well in Zone 7 for over 20 years; holds color in heat better than most other *T. occidentalis* types; 6 to 10' high 4 to 5' wide.
- 'Sunkist'—Good yellow foliage on tips/borders of sprays on a broad pyramidal plant, 10 to 15' high by 4 to 5'.
- Technito® ('BaliJohn', PP 15,850)—Compact pyramidal form, more dense than 'Techny'; appears slower growing; retains dark green color; 6' by 2 1/2'; have seen in Minnesota in Bailey's production and evaluation areas; Bailey Nursery introduction.
- 'Techny' ('Mission')—Broad-based, pyramidal form to 10 to 15' (25'); excellent dark green foliage year-round; good hedge plant; slow-growing; probably the best form for northern gardens; extremely popular; discovered in Mission Gardens, Techny, IL.
- Techny Gold™ ('Walter Brown', PP 16,280)—Witnessed at Raulston as 'Emerald Variegated'; foliage sprays tipped yellowish but not very impressive; heat may play a role in diminishing yellow intensity; have seen photos and plant appears quite attractive; listed as "burn resistant showy gold foliage", maybe in Zones 4 and 5.
- 'Teddy'—A fuzz ball 12 to 15" high with juvenile foliage; have seen in Europe and not sure about identity; looks more like a *Chamaecyparis*.
- 'Umbraculifera'—Dwarf, globose, depressed, compact form, 2 to 2 1/2' high, 4 to 5' wide; foliage glaucous, bloomy.
- 'Wansdyke Silver'—I had this form under *T. plicata* but was off-base; compact pyramidal; white-splashed foliage sprays; attractive initially and then lost all variegation, completely green; slow growing, 'Green Giant' about 35', 'Wansdyke Silver' 8' in same time frame.
- 'Wareana'—Pyramidal, low, dense; leaves bright green, developing thick, leathery green foliage, tinged blue, without a brown tinge; 35-year-old plant is 8' tall; good for northern areas.
- 'Wintergreen' ('Hetz Wintergreen')—Columnar pyramidal form holding good green winter color; coarser than other selections; 20 to 30' high, 5 to 10' wide; faster-growing than most *T. occidentalis* cultivars; may display better shade tolerance.
- 'Woodwardii'—Globular form, wider than high; foliage dark green, turning brown in winter; 72-year-old plant is 8' by 18'; a popular form; not preferable to some of the smaller globose or rounded types; common in cemeteries in the Midwest, not the most appealing plant for placing by a loved one.
- 'Yellow Ribbon'—Young growth yellow-orange maturing to green, bronze in winter; upright pyramidal selection, slow growth, 10' by 3' at maturity.

PROPAGATION: Cuttings made from current year's wood, taken with a heel, rooted well when taken each month in November through March. Cuttings taken in and after January rooted a little more quickly. Have collected cuttings of several clones and rooted all with 3,000 to 5,000 KIBA, 3 perlite:1 peat, mist, bottom heat (70°F). Tissue culture has been successful, see *In Vitro Cellular Developmental Biology-Plant* 29(2):65–71 (1993).

NATIVE HABITAT: Eastern North America (Nova Scotia to Manitoba, south to North Carolina, Tennessee and Illinois). Introduced about 1536.

RELATED SPECIES: I offer several additional species which may appear occasionally in arboreta and botanic gardens. They are inferior to the better forms of the three primary species.

Thuja koraiensis Nak., (thū'ya kôr-ē-en'sis), Korean Arborvitae, is usually a broad, rather irregular, 2 to 5' high, spreading shrub of no great beauty. I have seen it in the Midwest during the winter where it pales by comparison with 'Techny', 'Nigra', and others. The foliage is blue-green above with distinct whitish markings below. The shoots are quite flattened and the branches procumbent-ascending. Wilson mentioned seeing

the species in Korea from sprawling shrubs to slender, graceful, narrowly pyramidal trees reaching a maximum height of 25 to 30'. The plants I have recently observed and acquired are shrubby with distinct silver undersides to the foliage. Virtually every visitor asks the plant's identity. Two forms, both shrubby, maintained the greenest (blue-green) winter color in the Georgia trials. 'Glaucia Prostrata' was the name of one. The other looked like 'Glaucia Prostrata'. At Hillier, a graceful pyramidal form, almost *Chamaecyparis nootkatensis*-like in outline, made a splendid small ornamental conifer. This form, or a similar tree-type, would prove useful in the United States. Witnessed a tree type at Rosemoor, March 14, 1999. Northeast China, Korea. Introduced 1917 by E.H. Wilson. Zone 5 to 7.

Also worth mentioning is *Thuja standishii* (Gord.) Carr., (thū'ya stan-dēsh'ē-ī), Japanese Arborvitae, with a broadly conical crown, slender trunk, and shaggy, deep red bark. The branch sprays arch, ultimate divisions are 1/16" wide, sprays are bright green to dark on upper side, and glaucous with whitish spots beneath. Foliage is semi-weeping lending a shaggy appearance. Bruised foliage has the fragrance of lemon verbena. Cones are oblong, about 10-scaled, and 3/8" long. Probably 20 to 30' under cultivation, larger in the mountains of Honshu and Shikoku to 100'. The broad head may be the greatest difference from the other species. Actually a beautiful specimen but prone to winter discoloration. In March 1996, I visited the Missouri Botanic Garden, St. Louis and witnessed a handsome ±15' specimen that was dark green. Cuttings were granted, rooted, with plants growing in Georgia. Based on one year's evaluation in containers, the winter foliage color is a disappointing yellow-brown-green. Handsome plant in Coker Arboretum, UNC, that maintained dark green winter needle color. This is one of the parents of 'Green Giant'. Central Japan. Introduced by Robert Fortune in 1860. Zone 5 to 6(7).

Thuja orientalis L. — Oriental Arborvitae (This plant has had its name changed to *Biota orientalis* L. and *Platyclusus orientalis* (L.) Franco., the latter being more correct. I am staying with the old name because it keeps similar plants together.)

(thū'ya ôr-i-en-tā'lis)

LEAVES: Smaller than those of other species, distinctly grooved on the back, those on main axis about 1/12" long, triangular, ending in a blunt point, not pressed close to the shoot, those on the finer spray about 1/16" long, closely pressed, green on both surfaces, bearing minute stomata, giving off a slightly resinous odor when bruised but not as aromatic as other species treated herein. Branchlets arranged in a vertical plane.

CONES: Ovoid, fleshy, glaucous green before ripening, 3/4" long, 6 to 8 scales, each with horn-like process or hook.

SIZE: 18 to 25' high by 10 to 15' in width; however, can grow 30 to 40' high but this is seldom realized under cultivation; co-national champions are 58' by 35' in Leavenworth, KS and 50' by 36' in Saline, KS.

HARDINESS: Zone (5)6 to 11; has performed poorly at the Morton Arboretum, Zone 5.

HABIT: A large shrub or small tree of dense, compact, conical, or columnar habit when young with the branchlets held vertically, becoming in age loose and open and not so markedly vertical; composed of many slender branches which tend to bend and break in ice and snow; quite difficult to "pin down" actual habit for some forms are loose, open, almost tree-like with stringy foliage rather than typical flattened sprays; Will Corley had several seedlings in his Griffin, GA tests and I have observed the same type of plants at Woodward, OK in the plant material center; these forms were 20 to 30' high.

RATE: Slow to medium.

TEXTURE: Medium-fine.

LEAF COLOR: Bright yellow-green to grass green in youth changing to a darker green when older, often discolours in northern and southern (at least Zone 7) climates becoming yellow-green-bronze-brown in cold weather. Foliage color transitions are notable. With advent of warm weather (Athens) leaves often lose ugly winter color by mid to late March, assume green, blue-green, yellow, gold coloration; hold yellows, etc., into late spring, then heat reduces intensity; some are almost green by end of summer—early fall; then cold weather initiates the bronzing and browning. When the description states yellow, etc., for a given cultivar . . . don't believe it.

FLOWERS: Monoecious, terminal, solitary.

FRUIT: Cones roundish egg-shaped, 3/4" long, fleshy, bluish green before ripening; scales usually 6, ovate, each with a horn-like projection, the uppermost sterile; seeds 2 to each scale, ovoid, about 1/8" across, wingless; the wingless seeds distinguish it from the other *Thuja* species.

CULTURE: Transplant balled-and-burlapped or from a container; tolerant of most soils except those that are extremely wet; needs less moisture than *T. occidentalis*; best if the winter atmosphere is dry, protect from sweeping winds; pH adaptable; does quite well in Southeast and Southwest; in Key West, FL, yes, Key West. I saw the species on several occasions, robust, full-bodied and as obvious as a sore thumb; obviously it requires no significant chilling to satisfy any bud rest; also the plants were growing in/on coral/sand/sea shells and appeared to flourish; I have seen the plant all over Savannah, GA, particularly in cemeteries; not as deer susceptible as *Thuja occidentalis*.

DISEASES AND INSECTS: Bagworm, spider mites, canker (*Seiridium* spp.); see list on general culture sheet.

LANDSCAPE VALUE: Useful for hedges and specimens but not of great value in the north central states, although commonly sold; used extensively in the South and Southwest where it is more adaptable; is more deer resistant than *T. occidentalis*; tremendous heavy wet snow induced bending and splaying in early March 2009 storms in Athens, did not notice breakage; several worthwhile cultivars that are a cut above the species; still remember a tour of the Aldrich Nursery, near San Antonio, TX and the 'Aurea Nana' was growing in the field. If this species could be mated with *T. plicata* or others, the offspring should offer great adaptability as well as a wealth of ornamental variation. As an aside, we grew about 250 seedlings from a misidentified *Thuja plicata* 'Collyer's Gold'; distinctly tight conical-pyramidal, gold-brushed foliage sprays. The plant was, in fact, a *T. orientalis* taxon, never observed before by the author but I now believe is 'Collen's Gold'. The seedlings segregated about 1:1; green:yellow with compact, nubbin-esque forms, to tall, slender, telephone-pole shapes. Colors ranged from green to blue-green, soft yellow to yellow-orange. Winter color on *all* was slight bronze to almost brown. Summer 2008, in their third year, and the evaluation is continuing. Many seedlings formed cones in 2nd or 3rd years. This variation points to the potential for *Thuja* improvement but also the reason for too many cultivars of minimal merit.

CULTIVARS: Many cultivars (40 or more) are known but few are available in everyday commerce. Bitner (2007) lists only 12. RHS Plant Finder 2008–2009 lists 30. Hillier (2002) describes 13.

'Aurea Nana' (Berckman's Golden Arborvitae)—Dwarf, dense, globular to ovoid form; to 5' tall, will eventually grow to 10' and larger; foliage golden yellow and finally light yellow-green, slightly brownish in winter; easily 20' with time, 18' by 12', barrel-shaped plant in Oconee Hill Cemetery, Athens.

'Baker'—Bright green foliage, densely set needles and broad conical shape; does well in hot dry places; grows 5 to 8' high in 8 to 10 years.

'Beverleyensis'—Upright cone-shaped to globe outline with time; soft golden yellow foliage turning bronzy gold in winter; may grow 10' high and wide with age; easily 20' with time; deer ate this clone.

'Beverly Hills'—Compact, pyramidal, 8 to 10' high; bright yellow, fern-like sprays; bright yellow-green in winter; listed by Spring Meadow, I have not observed.

'Blue Cone'—Upright pyramidal form with compact sprays of flattened branchlets of dark green foliage with a bluish cast; my eyes see more green than blue and the habit is almost upright egg-shaped.

'Bonita'—Dwarf form, broadly conical; new growth yellow-green, later light green at tops, darker green below; 3' high.

'Collen's Gold'—Narrow, upright-pyramidal habit, 20 to 25' by 4 to 6'; new foliage bright golden yellow, turning golden then bronzing in winter on slightly twisted branches.

'Compacta'—Pyramidal, dense, formal, slow-growing form; foliage glaucous green, tips plum-colored in winter.

'Conspicua'—A medium-sized to large shrub of dense, compact, conical habit with the sprays strongly vertical; foliage golden yellow and holding longer than most yellow selections; probably the true "Berckman's Golden Biota."

'Elegantissima'—Narrow pyramidal, 10 to 12'(20') by 4 to 5'; foliage in flat sprays, emerges bright golden yellow, maturing to yellow-green, brown in winter.

'Filiformis Aurea'—Similar to 'Filiformis Erecta' but having more yellow-green foliage in summer.

'Filiformis Erecta'—When young, plants have upright cord-like branching habit, eventually forming upright oval-shaped shrub with light green foliage, more brownish in winter.

'Fruitlandii'—Upright-conical shape; rich deep green foliage.

'Franky Boy'—Dwarf compact type, 30" by 30"; thread-like golden yellow foliage fading to yellow-green, kind of Frankensteinish.

'Golden Ball'—Dwarf loosely rounded habit; soft golden foliage in summer, vivid orange-brown tints in winter.

'Golden Surprise'—Have only experienced seedlings of this golden foliaged, upright-conical form, both green and gold segregates; from the work of Dr. John Ruter, UGA.

'Green Cone'—Upright oval; bright green foliage produces abundant cones.

'Juniperoides'—Dense feathery blue-gray, needle-like juvenile foliage in summer changing to purplish plum in winter; rounded bushy habit, to 3' high.

'Meldensis'—Tight globose to broad columnar; feathery, light green, needle-like foliage, purplish brown in winter; dwarf growing, juvenile form.

'Minima'—Dwarf globose habit, becoming 3 to 4' high and nearly as wide at maturity; light yellow-green in spring, dark green in fall, brown in winter; 'Minima Glauca' with sea-green summer foliage, yellow-brown in winter, is known.

'Pyramidalis'—Over the years I have been confused by a large tree form with potential to grow 30 to 40' and rather loose, open, stringy foliage compared to the typical form; at Griffin, GA, Mr. Will Corley has grown several seedlings of this form for 15 to 20 years, they appear to be related to anything but the species; open, loose, gangly with bright green foliage; the cones are typical.

'Sanderi'—I do not think any plantspeople in the U.S. have this correctly identified; years past I witnessed the plant at a Georgia nursery . . . called a juniper, perhaps a *Chamaecyparis*; Hillier 2002 noted it is

a juvenile form with blue-green summer foliage, turning plum colored in cold; fickle plant and has not been long-lived under nursery production; may also be the same as 'Teddy?'; introduced in 1894 from Japan.

'Sieboldii'—Bright green foliage on a dense mounded plant that rarely exceeds 6' in height.

'Westmont'—Compact, globe-shaped (pyramidal in a photo I witnessed), slow-growing type with rich dark green foliage tipped with yellow from spring to fall; 24 to 30" high, 20" wide in 10 years.

'Xiangshanensis'—Dark green needles with prominent resin drops/glands on a plump conical tree/shrub; held winter color better than other *T. orientalis* in Georgia trials in 2005; however, in subsequent years noted some off color; extremely heat and drought tolerant.

PROPAGATION: Seed germination is relatively easy but stratification of seeds for 60 days at about 40°F may be helpful. Seed sown immediately upon removal from cones germinated in high percentages. Cuttings of this species are more difficult to root than those of *T. occidentalis*. Based on grafted *Chamaecyparis* taxa received from the West Coast, this species is a popular rootstock. Also, scale leaf explants produced entire plants via tissue culture, see *Acta Horticulturae Sinica* 24(1):75–78 (1997).

ADDITIONAL NOTES: Always look ragged in Midwest and East, especially during the winter; best reserved for southern and western states. Ancient specimens are dotted throughout cemeteries across America attesting to the species' tenacity.

NATIVE HABITAT: Korea, Manchuria and northern and western China. Introduced before 1737.

Thuja plicata Donn ex D. Don — Giant (Western) Arborvitae

(thū'ya plī-kā'ta)

LEAVES: On leading shoots, parallel to the axis, ovate, long-pointed, each with an inconspicuous resin gland on the back, up to 1/4" long, the points free; those on the ultimate divisions smaller, about 1/8" or less long, ovate, short and bluntly pointed, closely overlapping and often without glands, glossy dark green above, usually faintly streaked with white beneath but on some branches remaining green; emitting a tansy-like odor when bruised; similar to *T. occidentalis*, individual divisions not as wide and foliage more lustrous and dark green than *T. occidentalis*.

STEM: Branches horizontal, often pendent at the ends; branchlets in the same plane, much divided, the small lateral shoots falling after 2 or 3 years; often fern-like or stringy in appearance.

SIZE: 50 to 70' high and 15 to 25' wide; can grow in areas of the Northwest to 180 to 200' high; national champion 159' by 45' in Olympic National Park, WA.

HARDINESS: Zone (4)5 to 7; performing well at Morton Arboretum.

HABIT: A narrow, pyramidal tree with a buttressed base and often with several leaders; usually maintaining the lower branches; have seen old 80 to 100' high trees that were anything but narrow; still maintained branches and foliage to the ground.

RATE: Slow to medium, fast on some genotypes especially under nursery production.

TEXTURE: Medium.

BARK: Cinnamon-red on young stems; gray-brown to red-brown on old trunks, 1/2 to 1" thick, fibrous, and forming a closely interlacing network.

LEAF COLOR: A good lustrous dark green in summer and winter, although have observed considerable yellowing and browning in windswept locations in full sun, selections are being made for improved winter color.

FLOWERS: Monoecious, small, inconspicuous; staminate yellowish, pistillate pinkish.

FRUIT: Cones erect, cylindric-ovoid, 1/2" long, green in summer, brown in winter; scales 8 to 10, elliptic-oblong with usually the middle pair fertile; seeds winged, the wing notched apically.

CULTURE: Transplants readily balled-and-burlapped or from containers; prefers moist, well-drained, fertile soils and in the wild is found on moist flats, slopes, the banks of rivers and swamps, and is even found in bogs; occasionally found on dry soils but growth is usually stunted; moist atmosphere; full sun or partial shade; pH adaptable; have seen the species in the Vancouver, BC area and it grew everywhere from the steep slopes to the deep fertile valleys; truly an imposing evergreen if given optimum cultural conditions; handsome plants exist in the Midwest and East Coast and the species may be more adaptable than given credit; Raulston reported 2 to 4' of growth per year at Raleigh, NC; frequent trips to Oregon confirm this as one of the noble Western conifers; immense old trees dot the Portland-area landscape, when I visit the area nurseries I think to myself . . . "I wish we (East Coast) could grow them like that."

DISEASES AND INSECTS: Bagworm and heart rot.

LANDSCAPE VALUE: Useful as a specimen or for hedges in formal and semi-formal plantings, groupings, screens; a beautiful conifer when properly grown, some indication that the species may be deer resistant; common in France, Italy, Germany, Netherlands, and British Isles; in Zone 7 has jumped in the early years then shows occasional branch dieback; not sure of the cause; probably best adapted to Zone 7 and 8 of the

West Coast, certainly fine in 5 and 6 in the East; this is a beautiful arborvitae, arguably the aristocrat of the genus; the hybrid 'Green Giant' is a huge commercial success and more adaptable in the South than the species *T. plicata*.

CULTIVARS: Many more selections in Europe. The following cultivar list is derived from an article published by the author in *Nursery Management and Production* 14(4):14–15, 71–73 (1998) and updated with 8 new selections for the 6th edition. Bitner (2007) describes and/or illustrates 23; Hillier 2002, 16; RHS Plant Finder 2008–2009, 26.

'Albospicata'—Darker green foliage background, cream splatches on new growth, fades to green with maturity; strong grower; ascending branches.

'Atrovirens'—One of better large, pyramidal arborvitae types; 30 to 45'; vigorous like the species; excellent shining dark green foliage, muddy brown in winter; excellent cold hardiness; an excellent hedge form.

'Aurea'—Large form like species but slower growing; yellow foliage more or less irregularly scattered over the tree.

'Canadian Gold'—Broad pyramidal; brilliant gold foliage, similar to 'Sunshine'; described as 65' by 20'; introduced by Mitsch Nursery, Aurora, OR about 1980.

'Can-can'—Compact, upright conical habit; leaves tinged white on tips of new growth; maturing dark green; 20' by 8'.

'Clemson Select' ('Clemson #1')—Slower growing; broad pyramidal; cream highlights in new growth.

'Clemson Tiger' ('Clemson #2')—Larger than 'Clemson Select'; 30' by 8'; creamy highlights in new growth; cold hardy form with good green winter color; selected from Schoenike Arboretum, Clemson University, Clemson, SC; offered by Head-Lee Nursery, Seneca, SC and Nurseries Caroliniana, North Augusta, SC.

'Collyer's Gold' ('Colliers Gold')—Upright-columnar in youth; golden yellow foliage; similar to 'Stoneham Gold'; has not performed well in Georgia trials.

'Cuprea'—Dwarf broad pyramidal form, 3 to 4' high, wider at maturity; copper to bronze-yellow shoots, more green in summer; a seedling of 'Aurea'.

'Daniellow'—Tight-pyramidal-columnar form; lustrous yellow-gold foliage, becoming more golden with heat and sun; branch sport of 'Gelderland'; witnessed young plants at Griffith Nursery, has potential but jury is out until tested in-ground in the South; excellent yellow summer needle color in Minnesota.

Deerproof™ ('KLMfive')—Narrow pyramidal habit, 50' by 15 to 25'; lustrous dark green foliage with yellow tips; resistant to deer browsing; Roy Klehm selection.

'Doone Valley'—Broad-conical habit, 12' by 8'; green leaves with yellow tips, bronzing in winter.

'Dura'—Pyramidal, more open with loose, deep green foliage on young plants; slower growing than species, introduced by Timm & Co., Elmshorn, West Germany, in 1925.

'Emerald Cone'—Grows 24 to 40' in height, excellent lustrous emerald green foliage, disease-free; used on West Coast as a substitute for Leyland Cypress and Monterey Pine; introduced and available from Saratoga Horticulture Foundation, 15185 Murphy Avenue, San Martin, CA 95046; extremely slow-growing in the Georgia trials and did not hold good green color in winter; 'Green Splendor' grew three times as fast.

'Euchlora'—Narrow, conical, tall; soft rich green foliage; discovered in Bavaria in a private garden; excellent hardiness; excellent performance in Michigan; thought this might be the same as 'Green Giant' but origin belies my thinking.

'Excelsa'—Fast-growing, loose, pyramidal form; bright green foliage, discolors in winter; discovered in a cemetery in Berlin in 1962, introduced by Timm & Co. in 1941, named in 1947; excellent winter hardiness; apparently common in Pacific Northwest and British Columbia.

'Fastigiata'—A good columnar clone with a straight, slender outline and dense, rich green foliage; discolors in winter; somewhat firmer textured than species; over 40' high in Bedbury Pinetum, Kent, England after 49 years.

'Gelderland'—Tight pyramidal-columnar form with lustrous medium green foliage; discovered about 1980 in the Netherlands.

'George Washington'—Bright green with hints of yellow during new growth; columnar, full specimen form, 15 to 20'.

'Gracilis'—Loosely broad-conical, slow-growing; shoots finer and lighter than the species; needles small and light green.

'Gracilis Aurea'—Similar to above but shoots yellowish at their tips and nodding; not particularly attractive; can grow 20 to 25' high.

'Green Giant'—Somewhat of a genetic rover without a clear-cut taxonomic home; Martin and Tripp, *American Conifer Society Journal* 14(4):153–155 (1997), present "The Tale of *Thuja* 'Green Giant'"; I have collected three forms, one from the Arnold Arboretum, another from Manor View Nurseries, Monkton, MD, the last from Spring Grove, Cincinnati, OH; the Spring Grove form has been sold as *T. plicata* 'Spring Grove' and Spring Grove® ('Grovepli'); cuttings were rooted from the Spring Grove tree, plants grown side-by-side in the greenhouse and on a gravel pad, in two years "of watching," I saw absolutely no difference among the clones; described as a hybrid(s) between *T. standishii* and *T.*

plicata; excellent vigor in the field and containers in our trials, one field-grown plant was 5 1/2' high in two full growing seasons from a 12" high one-gallon container; habit is broad-pyramidal, lustrous rich medium green summer foliage, in winter foliage discolors to yellow-brown-green, literature says otherwise, I have seen too many plants North and South that were anything but winter green; on February 17, 1998, I evaluated the three clones(?) at the Center for Applied Nursery Research, Dearing, GA and all were bronze and significantly so, others who were with me concurred that the clones are so similar they cannot be dissimilar; plant greens with the advent of warm weather and is a terrific plant, simply not *green*, as promoted, through the seasons; certainly a worthy commercial item, 30 to 40' and larger; found in a seedling bed by S. Poulsen, Kristgaard, Denmark in 1935; thirteen-year-old plant is now about 35' high in Georgia trials with no signs of branch dieback (canker induced) or any type of injury; I planted three, 3' high plants in our Chapel Hill garden in 2006, now, May 2007, they are green and growing . . . but were a horrid yellow-brown-green during the 2006–2007 winter; anybody who sells them as non-browning/yellowing is looking through green-colored glasses.

Green Splendor™ ('Hoyt')—Upright conical selection with lustrous green sprays; fast growing; excellent in Georgia trials but still off-color in winter.

'Green Sport' ('Watnong Green')—Species type with good dark green color on February 5, 1998 at Longwood Gardens; Jeff Lynch graciously shared cuttings which rooted in 6 to 8 weeks; looked exceptionally good in the wind-swept nursery; have seen listed as synonymous with 'Watnong Green'; selected in 1960's by Watnong Nursery, Morris Plains, NJ.

'Green Survival'—Broad-conical habit, strong grower; bright green foliage summer and winter; originated as a seedling in the Darthuizer Nursery, Leersum, Holland.

'Grüne Kugel'—Small dwarf bushy form, 1' by 2 to 3'; dark green foliage, bronzes in winter; saw at February, 1998 Southeastern Flower Show; plant came from Larry Stanley, Boring, OR; tested in Georgia and went backward.

'Hillieri'—Compact form, 7 to 10' high and wide with age; needle color described as blue-green, bronze-brown in winter; cultivated by Hillier Nursery since about 1900.

'Hogan'—Dense pyramidal-conical tree, rich lustrous medium green summer foliage, slight off-color in winter in Zone 7, was told this is a grex including plants from a native population in Gresham, OR; Raulston distributed this as a clone; named after Hogan Road, Gresham, OR; has not held up well in Zone 7 with considerable branch dieback; Keith Warren, Horticulturist, J. Frank Schmidt, took me to see the native stand.

'Holly Turner'—Wide-spreading specimen, leaderless, producing lateral branches that arch gracefully downward; listed as 15' by 30'; found on Whidbey Island, WA, introduced by Heronswood, discovered by Dana Moffett, named after Holly Turner; in Georgia trials more shrubby than pendulous.

'Irish Gold'—Loose, somewhat open, irregularly branched with golden yellow shoots; tree-type habit; probably the most gold of all the "yellow" *T. plicata* types, awarded RHS Award of Garden Merit, see Lancaster, *The Garden* 121(12):760–761 (1996) for specifics; was told it had at least four other names . . . 'December Gold', 'Extra Gold', 'Royal Gold', 'Winter Gold'.

'Jacob Cline'—Tight pyramidal form with dark green foliage; selected by Gene Cline, offered in commerce by Bold Spring Nursery.

'Pumila'—Dwarf, dense pyramidal form, considered one of the true slow-growing forms of the species that parallels it in growth habit.

'Pygmaea'—Dense, compact form, meant to be identical with 'Pumila' but, based on photo records, distinctly different; dwarf form; blue-green foliage; irregular branching; 2 to 2 1/2' high, 2 to 3' wide.

'Rogersii'—Dwarf, oval-rounded form; higher than wide; 3 to 4'(6') after 25 years; golden yellow in summer, bronze-yellow in winter, dark green on the interior; same origin as *T. plicata* 'Cuprea'.

'Semperarescens'—Upright tree, appearing extremely open in youth, with the foliage tinged yellow; not particularly striking; introduced about 1923 by Dallimore and Jackson, England; specimens greater than 70' high are reported.

'Silvanus 1' (PP 18,036)—The description reads . . . exhibits medium dense branching and is suitable for use as a solitary garden plant or for use as a field hedge . . . that description could apply to a rutabaga.

Spring Grove® ('Grovepli')—See under 'Green Giant'.

Steeplechase® (PP 16,094)—Branch sport of 'Green Giant' discovered by Alan Jones at Manor View Farms, Monkton, MD; observed parent tree and it had all the worthy characteristics of *T. plicata*: shining dark green sprays and tight pyramidal, uniform habit; 25' by 14' in 10 years; resistant to deer browsing; plant is available in commerce.

'Stoneham Gold'—Broad conical form, semi-dwarf; interior foliage dark green, bright yellow new growth; 6 to 10' high, 2 to 3' wide.

'Stribling'—Dense thick column that grows 10 to 12' high, 2 to 3' wide.

'Sunshine'—More even yellow suffusion over the foliage; grows like the species; respectable foliage color, has held yellow foliage color in heat of Zone 7.

'Virescens'—Species type with good green winter foliage color at the Longwood Gardens nursery on February 5, 1998; not much difference between this and 'Green Sport' as viewed by the author; will require time to assess net worth, introduced by Mitsch Nursery about 1990–91.

'Watnong Green'—A wonderful lady introduced herself after a mid-February lecture on Long Island and told me about a good green form grown by the late Don and Hazel Smith, Watnong Nursery, NJ; she is tracking down plants/cuttings for my program; grows 40 to 50'; see under 'Green Sport', which appears to be a synonym.

'Whipcord'—Cute little mop-like, 5' by 4', mounding, weeping shrub with green, cord-like foliage that bronzes in winter; takes some getting used to.

'Winter Pink'—Dwarf, compact-mounded form with yellowish summer foliage, pinkish(?) in winter; photo shows it as a broad pyramid.

'Zebrina'—Kind of like an old friend, it tends to crop up in unexpected places; broad pyramidal outline with yellowish striped sprays (actually variable variegation pattern); have seen 60' tall plants in England, plants 60 to 70' (80' at Stourhead); the effect from a distance is a rather pleasing yellow-green; more than one 'Zebrina' resides in gardens and commerce; plant in my Georgia trials develops no yellowish markings but maintains good lustrous dark green color year-round; about one-fifth the size of 'Green Giant' in 14 years.

'Zebrina Extra Gold'—Slower growing with even more gold foliage; witnessed a plant at Trengwainton Garden, Penzance in March 1996 and 1998 and was literally blinded; brought cuttings home and was completely disappointed, simply no variegation in the heat; could this be the same as 'Irish Gold'?

PROPAGATION: Dormant seed lots have been encountered occasionally on which stratification in a moist medium at 34 to 41°F for 30 to 60 days stimulated prompt germination (variation among seed lots). Cuttings rooted well when taken in January. Best to collect cuttings after cold weather has set in. Raulston mentioned 95% rooting on December–January cuttings with 8,000 ppm IBA talc and mist. With 25 clones that I collected, rooting averaged 88% when treated with 5,000 ppm KIBA, 3 perlite:1 peat, bottom heat (70°F), and mist. Actually easy to root about anytime wood is firm. Cuttings will root faster if taken after cold and supplied bottom heat. In our Georgia work, we had a trial of 27 different *Thuja*, primarily *T. plicata* types, and all were easily rooted. This includes *T. koraiensis*, *T. standishii*, *T. orientalis* and *T. occidentalis*.

ADDITIONAL NOTES: Extremely handsome conifer; superior to *T. occidentalis* from an ornamental standpoint. Principal timber tree used for shingle manufacture in the United States and Canada. Is used for poles, posts, piling, boxwood, house-building, garden buildings, summerhouses, and green houses because of its durability. The Indians used the split trunks for totem poles and hollowed-out trunks for canoes. They used the inner bark for fiber, which was woven into mats, baskets, and hats. The roots are so tough that they were used for fish hooks.

Tremendous interest for the species and the better cultivars because of the enthusiasm of the late J.C. Raulston who promoted the plant ('Green Giant') as a possible alternative to Leyland Cypress and its ilk. Little did any of us know that its adaptability to Zone 7 and 8 would prove so positively dramatic. There are numerous cultivars but most have little to offer. The types that are tree-like with lustrous dark green foliage that holds in winter have a significant future in Zone 5 through 8. I collected clones as I lectured and traveled to campuses, arboreta, and private gardens based on winter foliage color. None of 27, except *T. koraiensis*, held dark green/green winter color, with some bronzing, in the replicated (3 plants/taxon) trials over the 3-year-period, 2002–2005.

NATIVE HABITAT: Alaska to northern California and Montana. Introduced 1853.

Thujopsis dolabrata (Thunb. ex L. f.) Sieb. & Zucc. — Hiba Arborvitae, False Arborvitae

(thū-yop'sis dol'a-brā-ta)

FAMILY: Cupressaceae

LEAVES: Shining dark green above, flat ones glandless on the back, oblong-spatulate, with a green keel and a hollowed silvery white stripe of stomata on each side; the side leaves larger, hatchet-shaped, ovate or linear-oblong, bluntly keeled, the more appressed part on the underside of branchlets with a broad white stripe.

BRANCHLETS: Arranged in opposite rows, the ultimate divisions much flattened, about 1/4" wide, sprays spreading in one plane.

SIZE: 30 to 50' high, 10 to 20' wide.

HARDINESS: Zone 5 to 7.

HABIT: Dense pyramidal evergreen of great beauty; the most magnificent specimen I have seen is located at the Isle of Mainau in Germany; in all appearances, at least from a distance, it resembles a fine *Thuja plicata*; fine plants at Anne's Grove Garden, Ireland.

RATE: Slow.

TEXTURE: Medium.

LEAF COLOR: Lustrous dark green on the upper surface and prominently marked with whitish streaks on the lower surface.

FRUITS: Subglobose, 1/2 to 3/4" long cones with 6 to 8, thick, woody scales, each ending in a horn-shaped boss, seeds winged.

CULTURE: Readily transplanted from a container; prefers moist, acid, organic soil, and protection from sweeping winds; full sun but will tolerate considerable shade; found in moist forests in Japan; prefers high atmospheric moisture; the further south the plant is grown, ideally the more shade should be provided; has not been comfortable in Zone 7 but I keep trying.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: To my knowledge the species is seldom found in the United States; it is a beautiful plant but, from a practical standpoint, probably not worth the commercial effort when there are so many other conifers that offer similar landscape effects; a good plant for the collector.

CULTIVARS:

'Aurea' ('Aurescens')—Beautiful yellow-gold form that I first experienced at Mt. Congreve, Ireland; certainly a collector's plant; young shoots more prominently yellow.

var. *hondae* Mak.—Branchlets densely arranged; larger cones; more compact in habit; beautiful evergreen; northern Japan.

'Latifolia'—Sprays somewhat rounded, concave like *Chamaecyparis obtusa* 'Gracilis'; low shrub, 2' by 3'; needles not as dark as species; perhaps as a textural accent; only plant ever experienced was at Raulston Arboretum, was not the same as 'Nana'.

'Nana' ('Laetevirens')—Dwarf form of rounded-mounded outline to 3' high; good dark green foliage, as I have seen and propagated it; several references say lighter green foliage than the species; perhaps there are several dwarf forms; forma *nana* (Endl.) Beissn. in GRIN.

'Variegata'—The sprays marked with creamy white blotches; interesting plant but will revert rather readily to the green form; have seen compact and more tree-like forms under this name.

PROPAGATION: Seeds are described as difficult. I have collected cuttings of 'Nana' in November, 3,000 ppm IBA-quick dip, peat:perlite, mist and in 10 weeks had 100% rooting; the variegated form is also easy to root; apparently even large forest trees are easily propagated by cuttings; was able to secure cuttings from the finest specimen at Anne's Grove in June, treated them with 3,000 ppm KIBA, 3 perlite:1 peat, mist and all rooted by the end of summer.

NATIVE HABITAT: Central Japan. Introduced 1861 to America.

Thymus serpyllum L. — Mother-of-Thyme, Wild Thyme

(thī'mus sēr-pī'lum)

FAMILY: Lamiaceae

LEAVES: Opposite, simple, ovate or elliptic to oblong, 1/4 to 1/2" long, about one-half as wide, obtuse, broad-cuneate, gray-green to medium green, glabrous beneath or pubescent and ciliate; petiole—short; dotted with oil glands.

SIZE: 1 to 4" high.

HARDINESS: Zone 4 to 8.

HABIT: Prostrate, weak subshrub or nearly herbaceous perennial; spreading, trailing, with rooting stems which ascend at the ends.

RATE: Slow.

TEXTURE: Fine in leaf; hardly noticeable in winter.

LEAF COLOR: Medium green although the numerous cultivars and other species offer grayish, bluish, yellowish green, whitish margined, and yellowish colored foliage.

FLOWERS: On the species rosy purple, 1/4" long; June through September; borne in dense terminal heads; the flowers are beautiful and one can walk by Thyme without ever noticing it underfoot but the bright flowers make it come alive; the bees appreciate the flowers and from same manufacture a delicious honey.

CULTURE: Easily moved as clumps or from containers in spring; prefers dry, calcareous, well-drained soil in a sunny location; if over-fertilized or the soil is too rich the stems become tall and weak and the plant loses its dainty character; plant 6 to 12" apart and they will fill in adequately in one growing season; makes an excellent cover for gentle slopes, a filler among rocks, dry walks, and ledges, or a crevice plant for walls, terraces, sidewalk cracks, and the like.

DISEASES AND INSECTS: Apparently there are very few problems associated with the species although root rot and the ground mealybug have been noted.

LANDSCAPE VALUE: As discussed under culture this species and the many cultivars are well adapted for rocky, dry slopes, as an edging plant, ground cover, or among stepping stones; will endure a modicum of mowing and occasional tramping; in Stockbridge, MA, not far from Naumkeag, the species has naturalized in a dry, sandy field; actually provides swaths of color in June–July that would otherwise be dead grass.

CULTIVARS: Over 40 cultivars are known. I have had great difficulty locating specific names for many of the different flowering and foliage clones which exist.

'Albus'—Possesses white flowers.

'Citriodorus' (Lemon Thyme)—Lemon odor; will grow into a spreading, small shrub about 1' high; considered a species, *T. ×citriodorus* (Pers.) Schreb.

'Coccineus'—Has bright red flowers.

'Lanuginosus' (*T. lanuginosus* Mill. non Hort.)—A type with gray-pubescent leaves and the appropriate name, Woolly Mother-of-Thyme.

'Roseus'—A pink-flowering clone.

Other clones with lavender flowers, white leaf margins, and yellow coloring in the leaves are known.

PROPAGATION: Very easy to root from cuttings or simply divide the plant.

ADDITIONAL NOTES: *Thymus* contains 350 species and hybrids, most notably *Thymus ×citriodorus* (Pers.) Schreb. which embodies many cultivars. I have observed Thyme collections as far north as Minneapolis. In our garden, the thymes are lovely in spring and early summer and all but disappear by fall. Excess humidity, soil moisture, inadequate drainage, and heavy shade spell doom. Bonnie and I have tried about 12 different types and have none to recommend as good doers. Small plant in the Chapel Hill garden has persisted on a rather dry slope forming about a 1/2" high carpet.

NATIVE HABITAT: Europe, western Asia, northern Africa. Cultivated for centuries.

Tilia americana L. — American Linden or Basswood

(til'i-a a-mer-i-kā'na)

FAMILY: Tiliaceae

LEAVES: Alternate, simple, broad-ovate, 4 to 8" long, almost as wide, abruptly acuminate, cordate to truncate at base, coarsely serrate with long-pointed teeth, lustrous dark green and glabrous above, light green beneath, 3 to 5 principal veins arising at the base, with tufts of hair in the axils of the lateral veins, wanting at base; petiole—1 to 3" long, glabrous.

BUDS: Terminal-absent, laterals-1/4 to 1/3" long, somewhat flattened, often lopsided, divergent, brown, reddish brown or greenish, smooth or slightly downy at apex, bud shaped like a teardrop, 2-scaled.

STEM: Moderate, smooth gray-brown, shining brown or greenish red, covered with a bloom, generally zig-zag, glabrous.

SIZE: 60 to 80' in height with a spread of 1/2 to 2/3's the height, but can grow to 100' or more; national champion is 89' by 87' in Montgomery County, PA.

HARDINESS: Zone 3 to 8(9).

HABIT: Tall, stately tree with numerous, slender, low hung, spreading branches; pyramidal in youth; at maturity the lower drooping down then up, forming a deep, ovate, oblong, or somewhat rounded crown.

RATE: Medium, 20 to 30' over a 20 year period although some authorities indicate the tree may grow 2 to 3' over a 10 to 20 year period; soil conditions largely govern the growth rate; in Minnesota tests both the species and 'Pyramidalis' ('Fastigiata') were 25' high after 8 years from 1 1/4 to 1 3/4" diameter whips.

TEXTURE: Coarse in all seasons, perhaps medium-coarse.

BARK: Gray to brown, broken into many long, narrow, flat-topped, scaly ridges, very tough and fibrous.

LEAF COLOR: Dark green above, paler green beneath, sometimes changing to pale yellow in the fall; usually the leaves fall off green or yellow-green; leaves on some trees tend to develop a brownish cast in mid-September and actually become unsightly; this seems even more pronounced if the summer was extremely dry; common in the Great Smoky Mountains National Park on the banks above streams; easily identified by large leaves and particularly the silver-backed leaves (tied to *T. heterophylla*).

FLOWERS: Perfect, pale yellow, 1/2" wide, fragrant, borne in 5- to 10(15)-flowered, 2 to 3" wide, pendulous cymes in mid to late June; bees supposedly make the finest honey from these flowers; bracts spatulate, 3 to 4" long.

FRUIT: Not clearly defined, but termed a nut-like structure, 1/3 to 1/2" long, grayish tomentose, subglobose, of no ornamental value, thick-shelled, without ribs.

CULTURE: Transplants readily; prefers deep, moist, fertile soils and here reaches maximum size but will grow on drier, heavier soils and is often found in the wild on the slopes of hills, even in rocky places; pH adaptable; full sun or partial shade; not particularly air pollutant tolerant.

DISEASES AND INSECTS: Anthracnose occasionally occurs on the European lindens, leaf blight, canker, leaf spots, powdery mildew, *Verticillium* wilt, linden aphid, Japanese beetle, elm calligrapha, European linden bark borer, linden borer, walnut lace bug, caterpillars, basswood leaf miner, elm sawfly, thrips, galls caused by Eriophyid mite, scales and linden mite can be and often are serious problems; the foliage feeding insects can damage the trees as they strip them of almost all foliage.

LANDSCAPE VALUE: A handsome native tree which perhaps should be left in the woods; in the southern Appalachians, in rich coves, along streams, in floodplain soils, the species is relatively common, the large leaves, often silver- or gray-backed are prominent; definitely not for the small property; perhaps parks, golf courses, and other large areas; for five editions I downgraded this species in favor of the European species; an immense mistake as I witness thriving specimens from Minnesota to Georgia; with selection this could become the next *T. cordata* with a broader adaptability range; great tree at Jefferson's Monticello.

CULTIVARS:

American Sentry™ ('McKSentry')—Uniform, symmetrical, pyramidal habit; branches silver-gray in youth; 45' by 25 to 30'; reported to be the most Japanese beetle resistant linden; McKay Nursery introduction, Waterloo, WI.

'Boulevard'—Narrow pyramidal; dark green summer foliage, yellow fall color; 60' by 30'; Zone 3; Bailey Nurseries introduction.

'Dakota'—A round-headed form introduced by Ben Gilbertson, Kindred, SD.

'Dentata'—Coarse serrations; as I viewed it at Hillier not that different from the species.

'Douglas'—Luxuriant deep green foliage; upright specimen tree growth with little staking or pruning; develops into broad pyramid; a Klehm introduction.

'Fastigiata'—A distinct pyramidal form, certainly not fastigate, which could be used in restricted growing areas; not a bad looking tree; spreads out a bit with age; selected in Rochester Parks about 1927.

Frontyard® ('Bailyard')—Form with symmetrical branching, broad-pyramidal, 60 to 75' by 40'; as witnessed at Minnesota Landscape Arboretum July 20, 2005, tighter, more densely branched than seedlings, leaves dark green; Bailey Nurseries selection.

Legend™ ('DTR 123')—Distinctly pyramidal with a central leader and excellent branching structure; thick dark green leaves are resistant to late season discoloration which often renders those of the species unsightly; winter stem and bud color is red; 55-year-old parent tree is 55' high and 36' wide; a Wandell introduction.

'Lincoln'—Slender-upright compact form with dark green foliage; yellow in autumn; 35' by 25'; a Klehm introduction.

'Nova'—Listed in RHS Plant Finder 2008–2009.

'Redmond'—Originally listed as a *T. xeuclora* form but more properly included here; densely pyramidal with large leaves that are intermediate between *T. americana* and *T. xeuclora*; introduced by the Plumfield Nurseries of Fremont, NE in 1927; makes a handsome street or lawn tree; I have thoroughly examined this cultivar and find it to differ from *T. xeuclora* in stem color (gray-brown-maroon on top, underside often greenish brown) and buds (glossy, ovoid, 3/8" long, reddish); the leaves approximate those of *T. americana* rather than *T. xeuclora* in size and color; in Kansas tests, this was slow to establish and averaged only 9.6" per year over a 10 year period; 40 to 60' by 15 to 30'.

'Rosehill'—An improved selection, fast growing and developing an open crown.

PROPAGATION: *Tilia* seed shows a delayed germination because of an impermeable seed coat, a dormant embryo, and a tough pericarp. Seed treatments that consistently result in good germination have not been developed. Recommendations include removing the pericarp, etching the seed coat in concentrated sulfuric acid for 10 to 15 minutes, and then stratifying in a moist medium for 3 months at 34 to 38°F. Seeds will germinate the following spring if picked before fruit wall and bract turn gray to brown. See *Seed Sci. Tech.* 16(1):273–280 (1988). Cuttings have been rooted using mid-May to late June softwoods (Kansas), wound, 20,000 to 30,000 ppm IBA quick-dip, perlite:peat, and mist. See *The Plant Propagator* 24(2):15 (1978) for details. Typically the cultivars are summer budded on seedling understock.

ADDITIONAL NOTES: The wood of these trees is used for many purposes including furniture, boxes, cooperage, wooden ware, veneer, and food containers. The tough inner bark is sometimes used for making rope. Several valuable papers concerning *Tilia* have been published. Some of the information is utilized herein but for in depth information, see Santamour and McArdle, *J. Arboriculture* 11:157–164 (1985); Muir, *The Plantsman* 5:206–242 (1985); and Muir, *The Plantsman* 10:104–127 (1988). Lancaster, *The Garden* 120(7):394–395 (1995), discusses *T. henryana* Szyszyl. and *T. oliveri* Szyszyl., two relatively unheralded species. The former is beautiful in new leaf, emerging pink to bronze-red, covered with silvery pubescence,

the leaves maturing to lustrous dark green with long bristle-pointed teeth. *Tilia oliveri* is akin to *T. tomentosa*. I am unaware of large trees in the United States, although the Arnold Arboretum has accessioned *T. henryana*.

NATIVE HABITAT: Canada to Virginia and Alabama, west to North Dakota, Kansas and Texas. In the broadest interpretation ranging from Maine to Florida, west to eastern North Dakota, south to Oklahoma and Louisiana. Introduced 1752.

RELATED SPECIES: Somewhat crystal-ballish as to the exact taxonomic status of the closely related species and one reference, Duncan and Duncan, 1988, list *Tilia caroliniana* Mill., *T. floridana* (V. Engl.) Small, *T. georgiana* Sarg., *T. glabra* Vent., *T. heterophylla* Vent., and *T. monticola* Sarg. as synonyms. Also listed is var. *mexicana* (Schltr.) Hardin and extends the species into northeastern Mexico. I attempted to teach both *T. americana* and *T. heterophylla* to my Illinois students and most simply raised their eyebrows or winced. Translation: who are you kidding, nobody can identify these things.

Would make great sense to select superior clones from Southern provenances. I have tested *T. floridana* in Athens but have yet to experience great performance.

***Tilia heterophylla* Vent.** — Beetre Linden, White Basswood (Now merged with *T. americana*)
(til'i-a het-ēr-ō-fil'a)

LEAVES: Alternate, simple, ovate, 3 to 6" long, about as wide, gradually acuminate, obliquely truncate or rarely subcordate at base, finely serrate, with aristate teeth, lustrous dark green and glabrous above, beneath with close thick white tomentum or often brownish on the upper leaves, and with small tufts of reddish brown hairs; petiole—1 to 1 1/2" long, glabrous.

BUDS: Terminal—absent, laterals—1/4 to 1/2" long, prominently pointed, reddish maroon, glabrous.

STEM: Glabrous, relatively stout, reddish maroon.

Tilia heterophylla, Beetre Linden, also called White Basswood, is similar to the preceding but is typically a southern species.

Morphologically, very similar except for undersurface of leaf, which is densely whitish; flowers smaller (1/4" long) and 10 to 25 per inflorescence. I have reason to suspect that many trees labeled *T. americana* are, in fact, *T. heterophylla* and possibly were bought from southern nurseries. At Illinois, I taught this and *T. americana* with students forever bringing me samples to identify.

Many specimens were not clear-cut and apparently some forms of *T. heterophylla* are almost hairless below. Indeed, the tree is handsome but in my own mind probably does not deserve species rank.

Mr. Bill Wandell introduced a handsome upright form, 'Continental Appeal' (PP 3,770), with a distinct oval form and a tremendous heavy crown, the large lustrous leaves being distinctly silvery on the underside, an excellent plant where lateral space to spread is limited, quite urban tolerant and transplants readily. Current thinking includes this species with *T. americana* which means 'Continental Appeal' would be a cultivar of *T. americana*, although GRIN treats this species as var. *heterophylla* (Vent.) Loudon. Species grows about the same size as *T. americana* under landscape conditions. National champion 110' by 66' in Union, GA. Native from West Virginia to northern Florida, Alabama and Indiana. Cultivated 1755. Zone 5 to 9.

***Tilia cordata* Mill.** — Littleleaf Linden, Small-leaved Lime

(til'i-a kôr-dā'ta)

LEAVES: Alternate, simple, suborbicular, 1 1/2 to 3"(4") long, almost as wide and sometimes broader than long, abruptly acuminate, cordate, sharply and rather finely serrate, dark green and glabrous and somewhat lustrous above, glaucous or glabrescent and glabrous beneath except axillary tufts of brown hairs; petiole—3/4 to 1 1/4" long, slender, glabrous.

BUDS: Similar to *T. americana*—small, brown, about 1/4" long.

STEM: Slender, lustrous brown, color continuous from current season's growth inward, may be greenish brown, glabrous.

SIZE: 60 to 70' in height and 1/2 to 2/3's that in spread; can grow 80 to 90' high.

HARDINESS: Zone 3 to 7; have observed a few trees in Athens and Atlanta, some have lived, others died; some shade in afternoon has allowed several trees on the Georgia campus to develop into respectable specimens.

HABIT: Pyramidal in youth; upright-oval to pyramidal-rounded and densely branched in old age.

RATE: Medium, 10 to 15' over a 5 to 10 year period.

TEXTURE: Medium in all seasons.

BARK: Gray-brown, ridged-and-furrowed on older trunks.

LEAF COLOR: Dark shiny green in summer changing to yellow in fall; often, at best, only yellow-green, on occasion excellent soft yellow; 25-years past, jogging through Manchester, NH, an October chill in the air, numerous beautiful, clear yellow, Littleleaf Lindens saluting my progress (slow); great memory.

FLOWERS: Yellowish, fragrant, borne in 5- to 7-flowered, pendulous, 2 to 3" wide cymes in late June or early July; flowers before *T. tomentosa*; floral bract 1 1/2 to 3 1/2" long, 3/8 to 3/4" wide.

FRUIT: Globose nutlet, thin-shelled, slightly or not ridged, covered with a gray pubescence, finally glabrous.

CULTURE: Readily transplanted; prefers moist, well-drained, fertile soil; full sun; pH adaptable; found on limestone in the wild; quite pollution tolerant; one of the best street and city trees and widely used for same.

DISEASES AND INSECTS: See under *T. americana*; aphids with attendant sooty mold and Japanese beetles are often a problem; worthwhile study, *J. Arboriculture* 20(5):278-281 (1994), that reported the glabrous species had greater linden aphid populations than the pubescent species; I have noted these differences for *T. tomentosa* compared to *T. cordata* but the above is the first time it was quantified.

LANDSCAPE VALUE: Excellent shade tree for lawn, large areas, streets, planters, malls, and about any place a real quality tree is desired; can be pruned (and quite effectively) into hedges; the Europeans tend to use the tree much more as a pleached specimen or hedge than do the Americans.

CULTIVARS:

'Bicentennial'—Tight pyramidal-conical form with acute branch angles; small typical dark green leaves; Ohio Shade Tree Tests mentioned an upright oval habit.

'Bohlje' ('Erecta')—Form of narrow, upright habit that supposedly is well-suited to street tree use in urban areas; leaves small, orbicular, coloring yellow and holding late in fall.

Chancellor® ('Chancole', PP 2,712)—Fastigate in youth becoming pyramidal with age; dark green leaves; has good crotch development; 35' by 20'.

Corinthian® ('Corzam')—Compact pyramid; formal shape created by uniform spacing of limbs around straight central leader; dense branching; lustrous dark green leaves; leaves smaller, thicker and more lustrous than species; 45' by 15'; Lake County Nursery introduction; a small tree performed well at the Milliken Arboretum; excellent habit as young tree and more refined than species; described as resistant to Japanese beetles.

'De Groot'—Sturdy, upright tree with compact head; glossy dark green foliage; slower growing than most lindens; 40' by 25'.

'Fairview' (PP 3,259)—Strong, straight rapid growth; thick leathery dark green leaves are slightly larger than the species; well proportioned crown; matures as a liner about one grade larger than most *Tilia* of the same age; more informal habit than some cultivars.

'Firecracker'—Broad-pyramidal form; good branching character; leafs out about 2 weeks later than most cultivars.

'Glenleven'—Fast-growing selection with a straight trunk; more open than typical *T. cordata*; leaf 1 1/2 to 2 times size of 'Greenspire'; introduced by Sheridan Nurseries, Ontario, Canada; 50' by 35'; possibly a *T. xflavescens* selection.

'Golden Cascade'—Similar to 'Norlin' but with cascading branches, globe-shaped crown; golden foliage in fall; introduced by Wilbert G. Ronald, Jeffries Nurseries, Portage la Prairie, Canada.

'Green Globe'—A bushy round-headed form that is top grafted at 6 to 7' on *Tilia* understock; foliage is dark green; 15' by 15'.

Greenspire® (PP 2,086)—Maintains a single leader with a nice branching habit; widely used as a street tree; result of a cross between cultivar 'Euclid' and a selection from the Boston Parks; does well under difficult conditions; good dark green foliage; handsome tree; grew only 9.5" per year over a 10 year period in Kansas tests; 40 to 50' by 30'; have seen some of the early trees at Princeton Nursery which have maintained excellent form; listed as more susceptible to sunscald and mechanical damage, I am not sure this is the case, suspect that this being the most widely planted cultivar, the bark problems are more frequently associated with the clone.

'Handsworth'—Young stems are a light yellow-green; quite striking especially on young trees; also listed as *T. platyphyllos* form.

'June Bride' (PP3,021)—According to the introducers, Manbeck Nurseries, Inc., New Knoxville, OH, this clone is distinguished from other clones by the "unique combination of substantially pyramidal habit of growth, maintaining an excellent straight central leader, the branches are evenly spaced around the leader; the small-sized leaves are more glossy than those of the species, and flowers more abundant with 3 to 4 times as many"; have seen in Spring Grove in flower, it is a handsome tree and absolutely dripping with flowers.

'Morden'—Dense pyramidal crown; quite hardy; introduced by Morden Research Station in 1968; slowest growing in Minnesota tests over an 8 year period.

Norlin™ ('Ronald', PP 8,239)—Broad pyramidal form with strong branches; listed as sun scald resistant; dark green leaves; selected for adaptability to northern plains; have tested in Georgia where it simply does not grow; introduced by Wilbert Ronald, Jeffries Nursery, Manitoba.

'Olympic'—Symmetrical form with better branching; glossy dark green leaves; beautiful specimen at Schmidt Arboretum that puts Greenspire® to shame; vigorous grower; 40' by 30'.

'Pendula Nana'—Dwarf compact habit with pendent branches; strictly for the collector; Girard Nursery introduction.

Prestige® ('Norbert', PP 6,745)—Excellent form, shape and limb structure; slightly broader than Greenspire® but with controlled shape; fast-growing; easily headed in nursery production; shiny bright green leaves; 60' by 40'; Bill Wandell introduction.

'Rancho' (PP 2,092)—An upright-oval clone with small, glossy green leaves, good crotch development, and a medium-fine branch texture; has proven to be a good selection; flowers heavily with very fragrant, small, yellow flowers; 45' by 20'.

'Salem'—Upsweeping branches form rounded head; brilliant deep green foliage; 35' high.

Shamrock® ('Bailey')—Stouter but more open crown than Greenspire®; strong broad-pyramidal outline; more vigorous; typical foliage; 40 to 50' by 30'; Bailey Nurseries introduction.

'Shibamichi Gold' (PP 16,433)—Bright yellow new leaves that mature to chartreuse in summer; described as resulting from a controlled breeding program in Kawasguchi, Japan by Mr. Akira Shibamichi; patented by Hines Nurseries Inc., Irvine, CA.

Summer Sprite® ('Halka', PP 10,589)—Cute, diminutive form; dense, plump pyramid, 16' by 10', potentially larger; has grown well at Raulston and Milliken Arboreta; ideal for large container, topiary look, small formal allée; leaves lustrous, leathery dark green and wavy; good heat tolerance in Zone 7.

'Swedish Upright'—Narrow, upright in outline, old trees become pyramidal; as seen at Hillier, not very upright, 35' high tree.

'Turesi' ('Turesii')—Strong-growing, pyramidal form.

Unique™ ('Unizam')—Small, compact grower; leaves dark green, smallish, yellow-gold fall color; 25' by 15'; Lake County Nursery introduction.

'Winter Orange'—What a name! The stems are attractive red-orange-brown; buds reddish; small plant at Raulston caught my eye; might be a plant to coppice (cut back) to force long shoot extensions.

Have noted 'Dainty Leaf', 'Len Parvin', 'Lico', 'Monto', 'Plymtree Gold' and 'Roelvo' listed in RHS Plant Finder 2008–2009.

PROPAGATION: See under *T. americana*; 49% germination after 7 months cold-moist stratification; successful tissue culture shoot proliferation utilizing thidiazuron, see *Biologia Plantarum* 29(6):425–429 (1987); cultivars are budded on seedling understocks.

ADDITIONAL NOTES: Pellett et al., *J. Environ. Hort.* 6(2):48–52 (1988) presented valuable growth data on *T. americana*, *T. cordata*, *T. xeuropaea*, and *T. platyphyllos* species and cultivars after 8 years. The information is difficult to compare because the liners were slightly different sizes at the time of planting. Perhaps the most striking aspect is the similarity in growth among the many *Tilia cordata* cultivars.

Witnessed the first class *Tilia* collection at Minnesota Landscape Arboretum in mid-July 2008. Collectively, the best-looking trees in the Arboretum.

NATIVE HABITAT: *Tilia cordata* is native to Europe and has been planted as a shade tree since ancient times.

RELATED SPECIES:

***Tilia xeuclora* K. Koch** — Crimean or Caucasian Linden; more recently treated as *Tilia* 'Euclora' (til'i-a ū-klō'ra)

LEAVES: Alternate, simple, roundish ovate, 2 to 4" long and as wide, abruptly short-acuminate, obliquely cordate, finely and sharply serrate with mucronate teeth, lustrous dark green and glabrous above, pale green and glabrous beneath, except axillary tufts of brown hairs; petiole—1 to 2" long, glabrous.

BUDS: Glabrous, 1/4" long or greater, yellowish red to reddish above, green beneath.

STEM: Glabrous, slender, greenish yellow on bottom, light reddish brown on top, almost rose-brown.

Tilia xeuclora, Crimean Linden, is the result of a cross between *T. cordata* × *T. dasystyla*. This tree grows to 40 to 60' and half that in spread. Graceful in habit with the lower branches skirting the ground. Not as stiff as *T. cordata*. The leaves are a lustrous dark green. Other features are similar to *T. cordata*. Flowers produced 3 to 7 in 2 to 4" long cymes in July. The floral bract is linear-oblong, or narrowly lance-shaped, 2 to 3" long, 1/4 to 5/8" wide, glabrous, short-stalked. A bud may form at the point of insertion of peduncle into bract, and also in the first division of the inflorescence. The ovoid fruits are tapered to a point, covered with pale brown wool, and 1/4" long, slightly 5-ribbed. This is a rather handsome tree and in my opinion superior to *T. cordata*. Unfortunately, many trees are grafted and the basal suckers and sprouts become unsightly and a maintenance problem. The foliage is truly beautiful but like most lindens dies off green or yellow-green and never offers outstanding fall color. Still (retired, Ohio State) has successfully rooted this species from cuttings which could alleviate the suckering problem on grafted trees. Interestingly, in England this species is free of the troublesome aphid infestations that wreak havoc on *T. cordata*. The sooty mold that develops after the aphids finish feeding colors the branches almost black. English literature mentioned a bleeding canker that killed large trees. It is tolerant of air pollution and hot, dry conditions. 'Laurelhurst' is vigorous with straight, strong trunk, even, compact, broadly pyramidal crown, glossy dark green leaves. Zone 3 to 7. Originated about 1860 but its parentage is not clear cut.

***Tilia xeuropaea* L.** — Common or European Linden, also listed as *T. xvulgaris* Hayne. Former is correct according to *Kew Bulletin* 50(1):135–139 (1995) and GRIN. (til'i-a ū-rō-pē'a)

LEAVES: Alternate, simple, broad-ovate, 2 to 4" long, about as wide, short-acuminate, obliquely cordate or nearly truncate, sharply serrate, dark green and glabrous above, bright green beneath and glabrous except axillary tufts of hair; petiole—1 to 2" long, glabrous.

Tilia xeuropaea, European Linden, is another hybrid with *T. cordata* and *T. platyphyllos* the parents. Pyramidal in youth and develops a more rounded habit in old age than the previous species. What I typically see in England is a broad-oval outline, wider at base, with a rounded top, lower branches skirting the ground. Will grow over 100' with time and a 150' high specimen grew at Duncombe Park, Yorkshire. Stems and buds glabrous, usually intensely red-maroon, buds and stems smaller, more refined than those of *T. heterophylla*. Occasionally stems are slightly pubescent, reflecting the *T. platyphyllos* parentage. Flowers earlier than *T. cordata* and *T. xeuclora*, usually around early June (Urbana, IL). Floral bract 3 to 4 1/2" long, 1/2 to 7/8" wide. Fruits tomentose, hard-shelled, faintly 5-ribbed. Tends to sucker from the base and also forms burls

on the trunk. Probably not preferable to *T. cordata* and its cultivars. Widely used in Europe for allées, streets, parks, formal areas. Susceptible to aphid and red spider mite attacks with subsequent sooty mold infestation. Produced by stooling and most trees in Europe have been derived from a single clone. In my estimation, it is inferior to *T. cordata* and *T. xeuclora*. Goldcrown® with bright golden yellow young leaves and reddish stems that mature to green was introduced by Lake County Nursery; I suspect it is a rename for 'Wratislaviensis'. 'Pallida' is a broadly conical form with reddish brown branchlets and leaves whose undersurface is yellowish green, highly rated in the Ohio Shade Tree Evaluation tests. 'Wratislaviensis' produces new growth of a yellow color which eventually becomes green; there is a plant at the Arnold Arboretum. A sport of 'Pallida'. In the United States, certainly not preferable to *T. americana*, *T. xeuclora* and certainly the best forms of *T. cordata*. Zone 3 to 7.

***Tilia kiusiana* Mak. & Shiras.**
(til'i-a kī-ū-sī-an'a)

LEAVES: Alternate, simple, oblong-ovate, 1 1/2 to 2 1/2" long, obliquely rounded or subcordate at base, lustrous green above, light green below, pubescent in leaf axils; petiole—1/5 to 2/5" long.

Tilia kiusiana appears to the author as the perfect small tree for contemporary landscapes. Probably 20 to 30' by 8 to 15' at landscape maturity. The habit, gently conical-pyramidal with elegant, refined, arching branches that skirt the ground. Bark exfoliates in elongated strips and plates. Have only observed at the Arnold Arboretum. Unique among lindens. A potential "sleeper" for the industry and a source of genes for breeding. Zone 6 to 7. Southern Japan. Introduced 1930.

***Tilia platyphyllos* Scop. — Bigleaf Linden**
(til'i-a plat-i-fil'ōs)

LEAVES: Alternate, simple, roundish ovate, 2 to 5" long, about as wide, abruptly acuminate, obliquely cordate, sharply and regularly serrate, dark green and short pubescent or glabrous above, light green and pubescent beneath, especially on the veins, rarely nearly glabrous; petiole—1/2 to 2" long, pubescent.

BUDS: Terminal—absent, laterals—1/4" long, reddish green-brown.

STEM: Reddish green-brown, pilose on young stems, rarely glabrous.

FLOWERS: Borne about the same time as *T. xeuropaea*; generally the earliest flowering linden and soon followed by tomentose, 5-ribbed, hard-shelled, subglobose to pyriform, 1/3 to 1/2" long fruits.

Tilia platyphyllos, Bigleaf Linden, grows 60 to 80' high and larger. Not extensively planted in the United States although the few large specimens I have seen were extremely beautiful in foliage (dark green) and outline (similar to *T. cordata*). It has the largest leaves of the European species but in no way compares in size to our American species. Yellowish white flowers occur in 3-, sometimes 6-flowered, pendent, 3/4" long cymes and are about the first to open. Floral bracts are 2 to 5" long, 1/2 to 1 1/4" wide. Very variable and numerous types have arisen.

Cultivars include:

'Aurea'—Young twigs and branches yellow; most potent in winter; must be viewed close-up to be appreciated.

'Fastigiata' ('Pyramidalis')—Upright-oval in habit; branches strongly ascending.

'Laciniata'—Irregularly lobed leaves and considerably smaller tree than the species; not particularly handsome; several cut-leaf forms exist.

'Pendula'—A weeping form with spreading branches and pendant branchlets.

'Rubra' ('Corallina')—Young stems red in winter, not particularly bright.

'Tortuosa'—The branches are curiously curled and twisted; not a particularly handsome tree; Minnesota Landscape Arboretum grew this for a number of years.

Hillier (2002) lists 'Aspleniifolia' (leaves deeply divided); 'Orebro' (upright, forming broad conical crown); 'Prince's Street' (bright red stems in winter); and 'Streetwise' (upright habit, glossy dark green leaves, red stems in winter, Hillier introduction).

This species is supposedly easy to identify by the pubescent stems and leaves but this is not always true. The degree of pubescence varies tremendously from densely pubescent to almost glabrous. The ribbed nutlets may be the best feature when separating it from *T. cordata*, *T. xeuclora*, and *T. xeuropaea*. At

the gardens of Fountainbleu, numerous *T. platyphyllos* form extended allées. Most of the trees I examined were densely pubescent. Planted in Europe for centuries. In Germany, the species is quite common. In my perusal of American nursery catalogs, I did not find a single listing of this or the cultivars. Santamour and McArdle, *J. Arboriculture* 11:157–164 (1985) listed 25 valid cultivars. Zone 4 to 6.

Tilia tomentosa Moench — Silver Linden

(til'i-a tō-men-tō'sa)

LEAVES: Alternate, simple, suborbicular, 2 to 5"(6") long, about as wide, abruptly acuminate, cordate to nearly truncate at base, sharply and sometimes doubly serrate or even slightly lobulate, dark green and slightly pubescent above at first, white tomentose beneath; petiole—1 to 1 1/2" long, tomentose.

BUDS: Often partially covered with soft, short, white pubescence, green-red-brown in color, about 1/4" long.

STEM: Covered with a soft, short pubescence; the dense, short pubescent stems separate this species and *T. petiolaris* (*T.* 'Petiolaris') from the other commonly grown lindens.

SIZE: 50 to 70' high by 1/2 to 2/3's that in spread.

HARDINESS: Zone 4 to 7.

HABIT: Pyramidal when young, upright-oval to pyramidal-oval in old age; one of my favorite shade trees; can be effectively grown as a multi-stemmed specimen for in this way the light gray, smooth bark is maximally enjoyed; the largest tree I have seen was located in the Arnold Arboretum and grew next to an equally large and beautiful *T. cordata*; both over 60' in height with upright oval habits.

RATE: Medium, similar to *T. cordata*.

TEXTURE: Medium throughout the seasons.

BARK: Light gray and smooth, almost beech-like on trunks up to 8 to 10" diameter and eventually becoming gray-brown, ridged-and-furrowed.

LEAF COLOR: Lustrous, shimmering, glistening, gleaming dark green on the upper surface, silvery tomentose beneath; when the wind is blowing a nice effect is created as both leaf surfaces are exposed; have seen decent yellow fall color on occasion.

FLOWERS: Yellowish white, fragrant, supposedly narcotic to bees; late June to early July; borne in 7- to 10-flowered, pendulous cymes, generally the last *Tilia* to flower, bract 1 1/2 to 2 1/2" long.

FRUIT: Egg-shaped with a short point, 1/3 to 3/8" long, whitish pubescent, minutely warted, faintly 5-angled.

CULTURE: See under *T. cordata*.

DISEASES AND INSECTS: See under *T. cordata*.

LANDSCAPE VALUE: Good street tree as it tolerates heat and drought better than other lindens; overall less prone to insects and untidiness of the other species; I highly recommend this for residential plantings as it is an extremely beautiful ornamental shade tree; many years past, there was a sizeable and well-shaped about 30' tree at the Raulston. A grouping of 3 trees at Milliken are 25 to 30' by 20' in about 15 years and have produced great yellow fall color in early November.

CULTIVARS:

'Brabant'—Broad conical crown with a strong central leader; leaves dark green with yellow fall color; excellent street tree; Dutch selection.

'Chelsea Sentinel'—Distinct columnar habit, resembling 'Petiolaris' in its weeping habit and graceful leaves; original tree grew on the grounds of the Royal Chelsea Hospital, site of the Chelsea Flower Show; described by Hillier 2002.

'Erecta' ('Fastigiata')—An upright clone; as I have seen it not too different from the species especially with age.

Green Mountain® ('PNI 6051')—An improved rapid-growing form; develops a handsome, dense-headed, broad pyramidal to oval tree that is heat and drought tolerant; dark green leaves with silvery undersides; 50 to 70' by 40'; Princeton introduction.

Satin Shadow® ('Sashazam')—Dark green leaves with silver undersides; 50' by 40'; Lake County Nursery introduction.

Silver Dollars™ ('Sildolzam')—Broad, compact pyramidal outline; leaf size closer to *T. cordata*; 45' by 30'; Lake County Nursery introduction.

'Sterling' (PP 6,511)—Impressive, sculptured, broad pyramidal crown with lustrous dark green leaves, silvery on the underside; young leaves silvery; 30-year-old tree 45' by 24'; handsome grayish bark and uniform winter silhouette; resistant to Japanese beetle and Gypsy moth; a Wandell introduction.

PROPAGATION: See under *T. americana*.

ADDITIONAL NOTES: Considerable German literature that points to honeybee and bumblebee death after sampling the nectar of *T. tomentosa*, *T. petiolaris*, *T. dasystyla*, *T. xueuchlora* and others. One paper recommended that *T. cordata*, *T. platyphyllos*, and *T. xeuropaea* be no longer utilized in urban areas in Germany.

NATIVE HABITAT: Southeastern Europe, western Asia. Introduced 1767.

RELATED SPECIES:

Tilia mongolica Maxim. — Mongolian Linden
(til'i-a mon-gōl'i-ka)

LEAVES: Alternate, simple, ovate to broadly ovate, 1 1/2 to 3" (4") long and as wide, acuminate, truncate or cordate, coarsely serrate, serrations triangular, with slender points, often 3- to 5-lobed especially on vigorous shoots, bronze-red when first emerging, lustrous dark green and glabrous above, paler and glabrous below except for tufts of pubescence in axils of veins; petiole—1" long, glabrous, reddish.

Tilia mongolica, Mongolian Linden, is a small (30'), graceful, round-headed tree. The leaves are deeply cut (almost lobed), which makes the leaf unlike any linden leaf. The glabrous stems supposedly turn a good red in winter although most stems I have examined were reddish brown. Leaves may turn good yellow in autumn. Also is resistant to aphids. This tree received rave reviews early in its career but nurserymen and others have found it hard to grow, tends to flop, must be trained, grafted on *T. cordata*. In addition, it is subject to storm damage, ice, and snow. I have changed my assessment of this species and recommend growers and homeowners temper their enthusiasm. Perhaps the most notable aspect is that the leaf does not look like a Linden. A leaf spot has also been reported. 'Harvest Gold' (PP 12,232) was selected for its upright pyramidal habit, excurrent growth, 40' by 30', glossy dark green summer foliage, and consistent golden yellow fall color, introduced by Wilbert G. Ronald, Jeffries Nurseries, Portage la Prairie, Canada. Schmidt Nursery mentioned it is faster growing in the nursery than *T. cordata* cultivars. The foliage, as I witnessed, is much more *T. cordata*-like but larger. The lobes and jagged serrations of *T. mongolica* are not evident. A young tree in the Schmidt Arboretum was strongly upright, with long shoot extensions, showing none of the *T. mongolica* habit. A plant at Milliken Arboretum suffered from heat and drought in 2008. Native to China, Mongolia. Introduced 1880. Zone 3 to 5(6).

***Tilia* 'Petiolaris'** (formerly *Tilia petiolaris* DC. sensu Hooker), (til'i-a pet-i-ō-lā'ris),

Pendent Silver Linden, is closely allied to *T. tomentosa*, but differs chiefly in the pendulous, graceful branches. It makes a beautiful specimen tree and perhaps the finest in the country are located at Swarthmore College and the University of Illinois. Trees may reach 70 to 90' high, perhaps one-half this in spread. Interestingly, this species exhibited the best fall color of all the lindens in the Arnold's extensive collection. It was a uniform golden yellow and extremely effective. I highly recommend the tree for the individual who wants something different and better than the standard *Tilia cordata* syndrome. The petioles are longer than those of *T. tomentosa* but this is not a black-and-white trait for separating the two taxa. I believe *T. petiolaris* is nothing more than a selection of *T. tomentosa* and should correctly be listed as a cultivar. Recent literature lists this as *T. 'Petiolaris'*, a taxonomic change that was long overdue. Santamour and McArdle listed this as 'Pendula'.

The New RHS Dictionary of Gardening reconciles it to *T. 'Petiolaris'* as does Hillier 2002 and RHS Plant Finder 2008–2009. Supposedly, the bees find the flowers narcotic or poisonous and can be found in large numbers on the ground under such trees. I did not notice strange “bee-behavior” around the Illinois tree. It is interesting to note that although this tree was listed as a species, it is usually grafted. I would be interested in knowing what percentage of seed-grown trees exhibit the weeping tendency. ‘Orbicularis’ has somewhat more pendulous branches and a more conical crown; the petioles are shorter and undersides gray; may be a hybrid between ‘Petiolaris’ and *T. x euchlora*. There is a handsome specimen in Wisley Garden. Dr. Donald Wyman considered ‘Petiolaris’ the most beautiful of the lindens. Native to southeastern Europe and Western Asia. Introduced 1840. Zone 5 to 7.

Toona sinensis (A. Juss.) M. Roem. (formerly *Cedrela sinensis* A. Juss.) — Chinese Cedrela or Chinese Toon
(tōn'a sī-nen'sis)

FAMILY: Meliaceae

LEAVES: Alternate, pinnately compound, 10 to 20" long, leaflets 10 to 22, short-stalked, oblong to lance-oblong, 3 to 6" long, acuminate, base unequal on each side of midrib, remotely and slightly serrate or nearly entire, pubescent beneath on veins or finally glabrous; young leaves smell like onions when crushed; reddish bronze in color on newly emerging leaves, eventually medium to dark green; petiole—long.

BUDS: Solitary, sessile, short-ovoid, with about 4 short-pointed, exposed scales; terminal much larger.

STEM: Coarse, terete, puberulent; pith—large, homogenous, roundish, white becoming colored; leaf scars cordately elliptical shield-shaped, slightly raised, large; 5 bundle traces; no stipular scars; could be mistaken for *Ailanthus* on first inspection.

SIZE: 30 to 40' tall under landscape conditions; can grow 60 to 70' in the wild; often suckering and forming colonies.

HARDINESS: Zone 5 to 7; has survived –25°F, however, Morton Arboretum, Lisle, IL reported freeze injury almost every year.

HABIT: Upright-oval, single-stemmed and from a distance resembles *Carya ovata*, variable, may also be multi-stemmed or suckering.

RATE: Medium to fast.

TEXTURE: Medium-coarse in summer; coarse in winter.

BARK: Brown, peeling off in long strips similar to that of *Carya ovata* in appearance but on a reduced scale.

LEAF COLOR: Reddish purple when unfolding, gradually turning medium to dark green in summer; fall color is of no consequence, although yellow has been mentioned in the literature.

FLOWERS: Small, perfect, white, malodorous (fragrant is mentioned), campanulate, about 1/5" long, borne in pendulous, 12" long panicles in June.

FRUIT: Woody capsule, about 1" long and wide, with winged seeds, fruit looks like a wood rose, discovered a tree outside the Nation's Capitol with fruits littering the ground, actually quite attractive but not sufficient reason to grow the tree.

CULTURE: Quite adaptable to different soils; grows under extreme stress; possibly should be given a longer look.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Has been used as a street tree in Philadelphia, PA, Santa Barbara, CA, and Paris, France. Magnificent, noble specimen, about 70 to 80' high, long slender bole, gray-brown bark in long, loose, peeling strips, at Monticello, no doubt planted by Thomas Jefferson. I remembered it from a 1980 visit; Bonnie and I walked the grounds in 2007, still standing firm . . . good genes.

(leaflet)

CULTIVARS:

'Flamingo'—An interesting form with pink- to cream-colored new foliage that eventually changes to green; as I have observed it, the new foliage emerges brilliant, hot pink, then cream, and matures to green; originated in Australia around 1930 and the name was first published in 1981.

PROPAGATION: Seed apparently requires no pretreatment although reported success varies; a one-month cold stratification is suggested; root cuttings will produce shoots; collect in October and later; 'Flamingo' is grafted.

ADDITIONAL NOTES: Resembles *Ailanthus altissima* in morphological features except it does not bear the glandular teeth near the base of the leaflet and the leaves have an oniony smell. The young shoots are boiled and eaten as a vegetable by the Chinese. The tree was known to botanists since 1743, but was not introduced to Europe until 1862. By some strange happenstance this species was included in a planting on the Georgia campus. At first I thought it was *Ailanthus* but the onion smell gave it away. Has not performed well in the heat of the Georgia summers. Probably the most complete landscape treatment of the species is offered by Koller, *Arnoldia* 38:158–161 (1978).

NATIVE HABITAT: Northern and western China. Introduced 1862.

Torreya taxifolia Arn. — Stinking Cedar, Florida Torreya
(tôr'i-a taks-i-fō'li-a)

FAMILY: Taxaceae

LEAVES: Evergreen, spirally arranged, needles spreading in one plane, needle-like, linear-acicular, 1 to 1 3/4" long, flat, stiff, apices sharp to touch, lustrous dark green above, with gray-green stomatal lines below, short petioles; strongly malodorous when bruised.

BARK: Gray-brown, ridged-and-furrowed, forming almost woven pattern.

Torreya taxifolia is a small needle evergreen, usually loosely pyramidal in outline. Plants at the Biltmore Gardens are tree-like with somewhat open crowns while a large, 30 to 35' high specimen in Lee, FL is dense and broad pyramidal. The national champion is listed as 53' by 40' in Norlina, NC. The species is on the Federal Endangered List and suffers from a twig (shoot) blight. Research (*Plant Disease* 80:600 (1996)) points to *Pestalotiopsis microspora* as causal agent. It was isolated from plants throughout the native Florida range. Also, inoculated healthy plants produced stem cankers, necrotic areas and chlorosis on terminal leaves. Considerable effort to propagate and establish the species away from home base. Dioecious with the male cones borne singly in the axils of the needles of the previous year; the female in leaf axils of current season's growth. The olive-like seed is wholly enclosed by a leathery tissue, dark green with purplish stripes, bloomy, about 1 to 1 1/4" long, 1/2 to 3/4" wide. Seeds have been germinated and cuttings rooted. Certainly not a plant for the landscape but worth appreciating and preserving. Nicholson, *Natural History* 12/90, discusses "Chasing Ghosts" along the steep ravines of Florida's Apalachicola River in Florida and Georgia. Hiked Torreya State Park, Bristol, FL to experience the plant in the wild along the Apalachicola River. Witnessed one scraggly plant in dense shade on the slope above the river. Asked a park ranger the location of the species. She said, "off-limits, no visitors", I told her my affiliation and interest, she said, "off-limits, no visitors" . . . such is the elasticity of the government. Might mention that Atlanta Botanical Garden has a significant number of seedling plants, none everyday landscape specimens. Introduced 1840. Zone 6 to 9.

RELATED SPECIES:

Torreya nucifera (L.) Sieb. & Zucc., (tôr'i-a nū-sif'ēr-a), Japanese Torreya, forms a dense pyramid. The lustrous dark green needles are 3/4 to 1 1/4" long, linear-lanceolate and taper to a sharp apex. Needles are highly aromatic when bruised. The second year stems are reddish brown compared to the greenish stems of *T. taxifolia*. The naked seed is ellipsoid-oblong, about 1" long, green, faintly tinged purple. There is a handsome, ±40' high specimen on the Swarthmore College campus. From a distance, looks like *Taxus* on steroids. Several yellow-splashed cultivars, 'Gold Strike' and 'Variegata' are described by Bitner. Possibly the hardiest of the *Torreya* species. Japan. Introduced before 1764. Zone 6 to 8.

Trachelospermum jasminoides (Lindl.) Lem. — Confederate or Star Jasmine

(trā-ke-lō-spēr'mum jaz-min-oy'dēz)

FAMILY: Apocynaceae

LEAVES: Opposite, simple, evergreen, ovate-rounded, 1 1/2 to 3 1/2" long, 1/2 to 1" wide, abruptly acute, cuneate to rounded, entire, glabrous, leathery, new growth bronze-purple, lustrous dark green above, pale green beneath, with veins darker green creating a prominent mosaic; petiole—1/4" long, pubescent.

BUDS: Imbricate, 1/32 to 1/16" long, brown.

STEM: Slender, rounded, dark brown, pubescent, exuding a milky sap when cut.

Trachelospermum jasminoides is a twining evergreen vine or ground cover (10 to 12', possible to 20') with lustrous dark green leaves and fragrant, 1" diameter, 5-petaled, cream-white (tinge of yellow) flowers that occur in slender, stalked cymes. The flowers open from May to June (late April to early May in Athens) and sporadically thereafter and provide a delightful fragrance. Full flower May 10, 2007, coastal North Carolina. Flowers are produced on short laterals from previous year's growth, although some flowers appear to develop on new growth of the season. For this reason, prune after flowering. The plant requires support and will make an effective cover on any type of latticework. Pruning is a necessary prerequisite every year if the plant is to be kept in bounds. Has been used on the Georgia campus in a courtyard area where the fragrant flowers hold court. Can also be used as a ground cover in shaded situations. Prefers partial or full shade and moist, well-drained soils but is adaptable to a wide range of conditions including full sun. 'Bruce Martin' is a large leaf, cold hardy form, has survived outside in containers at Seneca, SC; Head-Lee Nursery introduction. 'Bronze Beauty' has bronze-colored leaves that are more elongated and less lustrous. 'Madison' is more cold hardy and the underside of the leaf is densely pubescent compared to the glabrous undersides of the typical form, probably var. *pubescens* Mak., introduced by the late Cedar Lane Farm, Madison, GA. 'Pink Showers' bears fragrant pink flowers (faded quickly in the UGA greenhouse). 'Silver Mist' is spotted and blotched white. 'Yellow' has yellow flowers, otherwise as the species, offered by Louisiana Nurseries. Have observed a very pretty form on which the leaves are bordered and blotched with white ('Variegatum'), the interior of the leaf is gray-green, exterior creamy. In winter creamy areas turn pinkish red to carmine. Can be used for a multiplicity of purposes. Easily rooted from softwood cuttings in June or July and could probably be rooted about anytime of year. Often grown as a glasshouse plant in the north. Japan, China. Zone (7)8 to 10. Actually tender in the vicinity of Athens, GA and should be sited carefully. Leaves were killed at -3°F but stems and buds survived. Purchased a variegated (cream-margined) form at Hannay's of Bath, England, listed as var. *wilsonii* 'Variegatum', supposedly hardier than the 'Variegatum' described above. Tested for several years in Athens and it never impressed, although container-grown plants, not winter protected, suffered no injury. 'Wilsonii' is described by Hillier 2002 as having attractive veins, turning crimson in cold weather. 'Big White Star', 'Japonicum', 'Major' and 'Waterwheel' are listed in RHS Plantfinder 2008–2009.

RELATED SPECIES

Trachelospermum asiaticum (Sieb. & Zucc.) Nak., (trā-ke-lō-spēr'mum ā-shi-at'i-kum),

Japanese Star Jasmine, is a degree hardier but to my knowledge is not as common in the southern landscape. The leaves are smaller (3/4 to 2" long, 3/8 to 3/4" wide), elliptic or ovate, dark glossy green, glabrous, with a 1/8" petiole and the main veins are almost white. It is apparently not as precocious as *T. jasminoides* and the flowers are yellowish white, 3/4" across at their mouth and fragrant. Have seen it used effectively as a ground cover on the Louisiana State University campus and Coastal Plain gardens. The calyx lobes are erect; in *T. jasminoides* they are larger and reflexed. Can be used in similar landscape situations. Although the species is described as growing 15 to 20', in the common landscape form it is a rather vigorous ground cover. I have not observed flowers on the typical ground cover forms. Also, the plant reacts to warm winter weather by deacclimating and subsequent late spring freezes kill the leaves. This happened numerous times to campus plantings, particularly those sited in full sun. 'Aureum' is a golden leaf type; looked like it would cook in the south. 'Compactum' is more restrained in growth habit. 'Elegant' is a small leaf form with extremely lustrous dark green leaves. I believe this is the same as 'Asia Minor'. 'Golden Rain' has soft yellow, fragrant flowers. 'Goshiki Kiri', with pink, white, green variegated leaves.

This may be the same as 'First Snow' which has pink new shoots, then green spots/specks/blotches on white background, eventually turning dark green with white veins (some leaves). Performs well in Athens. In 'Nortex' ('Nana'), the leaves are more lance-shaped. 'Oblanceolatum' has narrow, lustrous dark green leaves with silver veins and short internodes, makes a dense mat, hardy form from Clemson University test gardens offered by Nurseries Caroliniana. 'Ogon' all gold leaf selection; introduced by Ted Stephens, Nurseries Caroliniana. Salsa™ ('Ougon-nishiki') with bright red-orange leaves, yellow centers, maturing to green margins and yellow centers; slow growing but colorful; trademarked by Hines Nurseries. 'Theta', new leaves burgundy, narrow (linear), dark green with white central mid-vein. A creamy white-margined variegated form ('Tricolor'?) is known which has been utilized on the Georgia campus in a shady corner for ground cover purposes. The actual leaf color is similar to *T. jasminoides* 'Variegatum'. Many new cultivars, most with variegated foliage (Winter Beauty™ ('Hinvariegated'), 'Chameleon'), have entered the United States. Japan, Korea. Cultivated 1880. Zone 7 to 9.

Triadica sebifera (L.) Small (formerly *Sapium sebiferum* (L.) Roxb.) — Chinese Tallow Tree, Popcorn Tree

(trī-a-dī'ka se-bif'er-a)

FAMILY: Euphorbiaceae

LEAVES: Alternate, simple, broadly rhombic-ovate or suborbicular, 1 1/2 to 3" long and broad, abruptly acuminate, broad cuneate to truncate, entire, glabrous, medium green; petiole—1 to 2" long, slender, with 2 glands on petiole at junction of blade.

BUDS: Small, appressed, brownish.

STEM: Wispy, green, finally brown, glabrous, glaucous, dotted with small brownish lenticels, milky sap.

Triadica sebifera is seldom seen in the Piedmont area of

Georgia but becomes almost pestiferous in the Coastal Plain from South Carolina to Florida, Louisiana to Texas. Florida listed it as a noxious weed. The medium green leaves are shaped much like a poplar and the first impulse is to relate this tree to that genus. The leaves emerge later in spring than most deciduous trees and turn reddish purple in the fall. Fall color in the Athens area has been disappointing for seldom do all the leaves color at the same time; leaves toward the interior color first with a progression toward the periphery; often yellow, orange-red and purple-red are intermingled on the same tree; some trees show limited coloration. Leaves fall by late October on the Georgia campus and are in full coloration in late December in Orlando, FL. The gray bark is ridged-and-furrowed with the ridges becoming flattened and scaly. The yellow-green, 2 to 4" long, catkin-like flowers (male at apex, 1 to 5 females at base) are followed by brown, 1/2" wide, 3-valved capsules which open to expose the white, oval, waxy seeds (October). The tree is known as "Popcorn Tree" because of the appearance of the seeds. The seeds are not messy but do persist into winter and eventually result in numerous seedlings where conditions permit. Chinese Tallow Tree is adaptable to moist, dry, acid, and alkaline soils and full sun to moderate shade. It is a *rapid* grower easily making 2 to 3' and more a year especially in youth. The general shape is pyramidal-rounded and the canopy thin and airy. Grass can be grown up to the trunk. The ultimate height approximates 30 to 40'(60'). Makes a good, but not long-lived, tree for fall color in the southern states. The milky sap is poisonous. Orchard plantations occur in China. The waxy coat on the seeds is extracted by the Chinese for use in soaps and candles; hence, the name tallow. It has also been suggested as a source of oil and one estimate I read said it could supply 5% of the United States' oil needs. In our work, it became immediately evident that Chinese Tallow Tree was easy to propagate. I collected seeds with the white, waxy seed coat intact and directly sowed them. Within 4 weeks, most seeds had germinated. The seedlings exhibit tremendous vigor. I would speculate that because of the very rapid growth the species might have possibilities as a biomass source. Has been reproduced through tissue culture; see *Plant Cell Reports* 16:637–640 (1997). The tree was injured at 0°F and –3°F during the 1981–82 and 83–84 winters, respectively. Plants tend to harden late and early fall freezes may result in injury. A California reference listed 10 to 15°F as the breakpoint. Considerable deadwood was evident after the spring growth flush occurred. Will grow in Zone 7 but best in 8 to 10. Numerous studies with *T. sebifera* that show its amazing tolerance to flooding by fresh and salt water, the ability to compete and prosper in low light and full sun. Has become a terrible weed in coastal plain of the South and is outcompeting the native vegetation; see *Castanea* 58:214–219 (1993), *Canadian J. Forest Research* 20:573–578 (1990); and *Bulletin Torrey Botanical Club* 116:371–377 (1989). China. Cultivated 1850.

RELATED SPECIES:

Sapium japonicum (Sieb. & Zucc.) Pax. & Hoffm., (sā'pi-um ja-pon'i-kum), is similar except the female flowers occur singly on 1/2" long pedicels, rather than in the cymose clusters like those of *T. sebifera*. I have seen the plant several times and the fall color was a handsome reddish purple. The true *S. japonicum* has 3 to 5" long, 2 to 4" wide, abruptly-acuminate, deep green leaves on about 1" long petioles. Maybe a better tree than *T. sebifera* for fall coloration but is probably less cold hardy. Species has been misidentified in the United States but is distinct by virtue of the *larger* elliptic to obovate-elliptic leaves! At Hillier, flowers were just opening on June 8, 1999; flowers on *T. sebifera* are earlier. China, Japan, Korea. Zone 9, perhaps a Zone more cold hardy. Has survived at the Raulston Arboretum, Zone 7, for many years as well as Sarah P. Duke Gardens, Durham, NC. In fact, in full flower about mid May, 2008. Tree is smaller than *T. sebifera* in habit, at least those observed by author. Possibly 15 to 30' landscape range.

Tripterium regelii Sprague & Tak. — Regels Threewingnut

(trip-te-rēg'i-um rē'jil'ē-ī)

FAMILY: Celastraceae

LEAVES: Alternate, simple, oval or ovate, 2 1/2 to 6" long, 1 1/2 to 4" wide, acuminate at apex, broadly wedge-shaped to rounded at the base, blunt, incurved teeth, dark green and glabrous above except with minute down on the midrib when young; petiole—1/4 to 3/4" long.

STEM: Angular, warty, reddish brown.

Tripterium regelii is a rather rank-climbing or rambling, deciduous shrub-vine (scandent shrub) to 30' high. The yellowish white (green-white), 1/3" diameter flowers are produced in large, terminal panicles and these in turn are supplemented by flowers in the axils of the terminal leaves, the entire inflorescence up to 8 or 9" long and 2 to 3" wide, July–August. It is an attractive plant in flower and appears to be adaptable to varied soils. The 3-angled, greenish white, winged fruits are 5/8" long and 1/4" wide. There was a fine plant at the Arnold Arboretum (1979) that served as my first field specimen. Witnessed again at Mt. Congreve Garden, Ireland. Obviously, it is not common in commerce. Relatively easy to root from firm wooded summer cuttings. Manchuria, Korea, Japan. Introduced 1904. Zone 4 to 7.

Trochodendron aralioides Sieb. & Zucc. — Wheel-tree

(trō-kō-den'dron a-rā-li-oy'dēz)

FAMILY: Trochodendraceae

LEAVES: Alternate, clustered, spiraled, simple, evergreen, rhombic-obovate to elliptic-lanceolate, 3 to 6" long, 1 1/4 to 3" wide, obtusely acuminate, cuneate, crenate-serrate at terminal end, leathery, lustrous dark green above, paler beneath; petiole—1 to 3" long.

BUDS: Terminal about 1/4 to 1/3" long, imbricate, pointed, reminding of a *Rhododendron catawbiense* flower bud.

STEM: Green year-round, glabrous, aromatic when bruised.

Trochodendron aralioides is a virtual unknown in American gardens but occasionally appears (like Brigadoon) in collections. The habit is distinctly shrub-like, probably no larger than 10 to 20' high and half as wide. A 30', 4-trunked plant at Hillier, 1999. In the wild it supposedly reaches 60' or greater. The branching is somewhat horizontal and almost sympodial like a sassafras. The most aesthetic aspect is the handsome foliage, which although listed as dark green, is a more vibrant rich green that appears to stand out from other evergreens. Flowers are a bright green and occur in 2 to 3" long racemes in April–May. Each 3/4" flower has a spoke-like arrangement of 40 to 70 stamens, each 1/8 to 1/4" long, inserted on a broad disk. The fruit is a 3/4" diameter follicle. The few plants I have seen in cultivation were in shady protected locations free from winter sun and desiccating winds. I suspect moist, well-drained, acid soil suits it best. Probably only use is a novelty or collector's item in a semi-shady area of the garden. Found in mountain

forests in Japan, Taiwan and Korea. Seed germination was 92% at 82°F; seeds stored for 4 or 8 weeks also germinated in high percentages. Introduced 1894. Zone 6 to 7. Have tested the species in Zone 7 with no success. Heat is rate-limiting factor although trees grow successfully at the Coker and Raulston Arboreta, NC; in both gardens, with shade. Was a respectable specimen at Longwood Gardens, Zone 6. Hillier, 2002 reported the species unharmed and quite outstanding after the severe 1962–63 winter. As a footnote . . . during 1999 sabbatical, Hillier had a volunteer workday (Tuesday) once a month. I participated in a clean-up session in Brentry Woodland. Vegetation was thinned and I was responsible for cutting down a >20' high *Trochodendron* . . . I still feel shame and believe if there is a black mark on my soul, it resulted from this terrible act. By the way, I was told to remove the tree because there were too many.

Tsuga (Endl.) Carr. — Hemlock

FAMILY: Pinaceae

If I were forced to select but one conifer for my garden it would certainly be *Tsuga canadensis*. The species has multitudinous uses and the infinite variation in seed-grown material has resulted in the selection of numerous cultivars. The number of *Tsuga* species used in landscaping is small but they are considered among the most graceful and beautiful of large evergreen conifers. Nine to ten species have been reported, four occurring in the United States and the others in the Himalayas, China, Taiwan, and Japan. *Tsuga heterophylla* is the most important timber-producing species. Hemlock bark contains between 7 and 12% tannin, and in the United States that of *T. canadensis* was one of the principal commercial sources for many years.

MORPHOLOGICAL CHARACTERISTICS

Evergreen trees of graceful pyramidal habit with slender, horizontal to drooping branches. The bark is cinnamon-red color and furrowed. Buds are rounded and not resinous. Needles, borne on petioles, spirally arranged, more or less 2-ranked, flattened and grooved above, with 2 white stomatic bands below. Needle margin is toothed or entire and the apex is rounded, notched, or blunt-pointed. Male flowers are catkins and axillary on previous year's shoots. The greenish female flowers are terminal on previous year's lateral shoots with imbricated scales. Cones are pendulous and often produced in abundance.

According to Jenkins, *Arnoldia* 6:11–12 (1946), the name *Tsuga* is derived from a Japanese word, composed of the elements "tree" and "mother," meaning Tree-mother. Concerning the common name Hemlock, Sudworth states that the New York Indians use the descriptive name Oh-neh-tah, pronounced Hoe-o-na-dia or Hoe-na-dia, while the Indian name for the North Country (now Canada) was also Hoe-nadia, which means a land of the Hemlock.

GROWTH CHARACTERISTICS

Generally, the *Tsuga* species are stately, graceful, pyramidal trees and maintain their good characteristics in old age. The cultivars range from low ground cover types ('Coles Prostrate') to gracefully weeping ('Sargentii' or 'Pendula') to distinctly upright ('Fastigiata'). There are various globose types and the foliage colors may be whitish to yellow especially on the new growth.

CULTURE

Hemlocks should be moved balled-and-burlapped in either spring or fall. Container-grown material is also available and this allows greater flexibility in planting schedules. They can be planted on many soil types; however, good drainage, cool, acid soils, and adequate moisture are necessary. They will not thrive under hot, extremely dry conditions. Sweeping winds may be detrimental. They will withstand full shade; however, partial shade is preferable and best growth is attained in full sunlight. They will not withstand air pollution and are susceptible to salt damage. Pruning can be accomplished in spring or summer. Hemlocks withstand heavy pruning and for this reason are often used for hedges.

DISEASES AND INSECTS

Leaf blight, cankers, blister rust, needle rust, sapwood rot, hemlock borer, hemlock looper, spruce leaf miner, hemlock florinia scale, grape scale, hemlock scale, spider mites and other pests. Woolly adelgid (*Adelges tsugae*) has wreaked havoc on the species in New England and Middle Atlantic States; over time infestations lead to decline and death; any time I visit the upper East Coast the subject of woolly adelgid invariably surfaces; it has proven a bane to successful hemlock culture. Nitrogen fertilization increased hemlock susceptibility to woolly adelgid; see *J. Arboriculture* 17(8):227–230 (1991). Moved south into the Southern Appalachians. Whitish insects are evident on underside of needles (branches) in native stands. On-going work assessing resistant species. *Tsuga chinensis* is considered resistant but in the Georgia trials, simply lacked vigor. Bitner (2007) listed *T. caroliniana*, *T. diversifolia* and *T. sieboldii* as susceptible; *T. heterophylla* and *T. mertensiana* are not.

PHYSIOLOGICAL DISEASES

Sunscorch, drought injury—Hemlocks are more sensitive to drought than most other narrow leaf evergreens especially when sited in southern exposures and rocky slopes.

PROPAGATION

Seed dormancy is variable in hemlock, with some seed lots requiring pregermination treatment and other germinating satisfactorily without treatment. Cold stratification of mature seeds shortens incubation time and may substantially increase germinative energy, and is therefore recommended. General recommendation for *T. canadensis*, *T. caroliniana*, *T. heterophylla*, and *T. mertensiana* is 60 to 120 days at 41°F in moist sand. Some success has resulted from the use of cuttings but timing is critical and the rooting percentages are low. Most of the cultivars are grafted onto species understocks. For a detailed discussion of *Tsuga* propagation see Dirr and Heuser, 2006.

LANDSCAPE USE

Tsuga canadensis is used extensively for specimen, hedge, screen and grouping purposes. Often it is used in foundation plantings but care must be exercised in keep it in bounds over the years. This is quite simple for it can be maintained at a height of 3 to 5' by judicious pruning. *Tsuga caroliniana* is less common in landscapes but, by some authorities, is considered a better plant because of greater pollution tolerance. This is not true as it is susceptible to the adelgid and not as landscape adaptable as *T. canadensis*. The habit of Carolina Hemlock is a bit more stiff than Eastern Hemlock. I have observed it growing from the sides of rock mountain faces in the southern Appalachians. *Tsuga canadensis* makes one of the best evergreen hedges especially if pruned correctly. If individual shoots are removed every year (rather than shearing the entire plant) a more aesthetically pleasing effect is achieved.

Bean separated the two cultivars 'Pendula' and 'Sargentii', but according to Jenkins the nurseryman's stock has all been derived from the 4 original plants found near the summit of Fishkill Mountain (near Beacon City, on the Hudson River) by General Joseph Howland about 1870. The finder grew one in his own garden at Matteawan, NY, gave the second to Henry Winthrop Sargent (after whom the plant was named), of Fishkill; the third to H.H. Hunnewell, of Wellesley, MA, and the fourth to Prof. C.S. Sargent of the Arnold Arboretum. The second and third are dead but the first and fourth have made fine specimens. Most of the plants in cultivation have been grown from grafts; however, there are also seedlings, so some variation can be expected. The fascinating story of the Weeping Hemlock is told by Del Tredici, *Arnoldia* 40:202–223 (1980). Another good reference is del Tridici, Peter, *A Giant Among the Dwarfs: The Mystery of Sargent's Weeping Hemlock*, Theophrastus Publishing, 1983.

CULTIVARS

Amazing variety, simply too many to consider, counted numerous selections offered by various United States nurseries with 'Albospica', 'Aurea', 'Beehive', 'Bennett', 'Brandley', 'Cloud Prune', 'Cole's Prostrate', 'Curly', 'Everett Golden', 'Geneva', 'Gentsch White', 'Golden Splendor', 'Gracilis', 'Horsford Dwarf', 'Hussii', 'Jacqueline Verkade', 'Jeddeloh', 'Jervis', 'Lewisi', 'Minuta', 'Nana', 'Pendula', 'Rugg's Washington Dwarf', 'Stewart's Gem', 'Stockman's Dwarf', and 'Von Helm's Dwarf', each offered by at least three sources. Stanley & Son's online catalog for 2007–2008 lists more than 70 selections of Hemlock; fifty-two or so are listed in RHS Plant Finder 2007–2008. Hillier (2002) describes 35 cultivars. Bitner (2007) describes and/or illustrates 41 cultivars. A handful of seed is a potent force for good, but when the garden world is polluted by 100 similar cultivars, the introduction(s) become meaningless.

Tsuga canadensis (L.) Carr. — Canadian (Eastern) Hemlock

(tsū'ga kan-a-den'sis)

LEAVES: Almost regularly 2-ranked, linear, obtuse or acutish, 1/4 to 2/3" long, 1/12 to 1/8" wide, obscurely grooved, lustrous dark green above, with 2 whitish bands beneath, toothed, with a short petiole.

BUDS: Minute, ovoid, with hairy scales, light brown.

STEM: Young stems slender, grayish brown, hairy.

CONES: Small, ovoid, 1/2 to 1" long on slender pendulous stalks, light to medium brown.

SIZE: 40 to 70' in height by 25 to 35' in spread; known to 100' or more; national champion is 133' by 39' in Towns, GA; beautiful specimens in Joyce Kilmer.

HARDINESS: Zone 3 to 7(8); actually languishes in heat of Zone 7(8), although occasional good specimens occur.

HABIT: Softly and gracefully pyramidal in youth with tapering trunk becoming pendulously pyramidal with age; one of the most beautiful conifers.

RATE: Medium, 25 to 50' in 15 to 30 years.

TEXTURE: Fine.

BARK: Flaky and scaly on young trees, brown, soon with wide, flat ridges; on old trees heavily and deeply furrowed; freshly cut surfaces showing purplish streaks.

LEAF COLOR: New spring growth light yellow-green changing to a glossy dark green, underside of needles with two glaucous bands.

FLOWERS: Monoecious; staminate light yellow, pistillate pale green.

FRUIT: Cones slender, stalked, ovoid, apex nearly blunt, 1/2 to 1" long by approximately 1/4 to 1/2" broad, brown at maturity; hang like small ornaments from the branches.

CULTURE: Transplants well balled-and-burlapped if root pruned; amenable to pruning; an excellent subject for moist, well-drained, acid soils, rocky bluffs or sandy soils; English literature lists this species as more lime tolerant than any other *Tsuga*; in Urbana, IL there were many handsome specimens growing in calcareous soils; unlike most conifers tolerates shade well; can grow in full sun as long as it has good drainage and organic matter in the soil and there is no strong, drying wind to contend with; heavy soil from which water is unable to drain is not suitable; does not tolerate wind or excessive drought; plant in sheltered locations, avoid windswept sites and polluted conditions.

DISEASES AND INSECTS: Leaf blight, cankers, blister rust, needle rust, sapwood rot, hemlock borer, hemlock looper, spruce leaf miner, hemlock florinia scale, grape scale, hemlock scale, spider mites, hemlock rust, mite causes emerging foliage to turn rusty or yellow in spring (mites feed openly sucking juices from the young needles, caused by a tiny Eriophyid mite), bagworm, fir flat headed borer, spruce budworm, gypsy moth, hemlock sawfly, and woolly adelgid. Two physiological problems include sunscorch which occurs when temperatures reach 95°F and above. The ends of the branches may be killed back for several inches. Another problem is drought injury for hemlocks are more sensitive to prolonged periods of dryness than most other narrowleaf evergreens. Plants may die during extended dry periods. For all the problems mentioned, hemlocks under landscape conditions can prove to be reliable, handsome ornamentals if given proper cultural care.

The most significant liability to successful culture is the woolly adelgid and this singular pest has limited the use of hemlock in the northeastern and mid-Atlantic regions of the United States. Some indication that biological control of the adelgid may be possible from an arboreal oribatid mite. Apparently innocuous populations of the adelgid occur on *T. diversifolia* and *T. sieboldii* in Japan.

LANDSCAPE VALUE: Makes an extremely graceful evergreen hedge of value in almost any situation except city conditions; excellent for screening, groupings, accent plant and foundation planting; the most commonly planted of the hemlocks, popular over a wide area; one of our best evergreens.

CULTIVARS: At one time I considered including a long list of cultivars but decided against such a move when the long list looked end "list." There are prostrate, globose, mounded, weeping, fastigate and variegated forms.

Since the 1998 edition, more cultivars have been introduced and several books, including Del Tridici, Swartley, *Cultivated Hemlocks* (1984), Krüssmann, and van Gelderen and van Hoey Smith, offer greater coverage than this book. In the latter reference, 56 cultivars of *T. canadensis* were shown and I might add some are so ugly that they defy adjectives. In the summer of 1988, I had an opportunity to verify the collections in Mt. Airy Arboretum, Cincinnati, OH and the conifer collection, especially *Tsuga canadensis* cultivars, were neigh impossible to accurately verify. So many clones are virtually the same and when the differences are based on growth habit, i.e., compact, more compact, most compact, one is easily confused. Even 'Jeddeloh' in three or four areas did not look exactly similar. Iseli Nursery, Boring, OR listed 29 cultivars of *T. canadensis* (2008) while Larry Stanley's, on-line catalog for 2007–2008 lists 74 Hemlocks, 61 of which are *T. canadensis* forms. One of the premier growers of hemlock in New England, Weston Nurseries, Hopkinton, MA described only seven (2007), but their 'Westonigra' strain which I have seen in the fields of Hopkinton, with extremely good dark green needle color in winter, may be the best around. The moral is that more is not necessarily better, only more.

'Pendula' ('Sargentii', f. *pendula*)—A magnificent, broadly spreading, weeping form that is among the most handsome of all conifers; I have seen it used by water where it produced the effect of a green waterfall; as a single specimen or grouping it can be most effective; by no means a small plant although can be kept that way with judicious pruning; will grow 10 to 15' high, twice as wide; the late Professor C.E. Lewis of Michigan State likened it to a ghost, gracefully sweeping across the landscape; really an eye-catching plant and one that is frequently available in commerce; see *Arnoldia* 40:202–223 (1980); many weeping forms have been introduced and named; several notable specimens reside at Longwood Gardens, Arnold Arboretum, Planting Fields Arboretum, and Biltmore Estate.

PROPAGATION: Seed dormancy is variable so to insure good germination it is advisable to stratify the seeds for 2 to 4 months at about 40°F. Layering has been used successfully. Cuttings have been successfully rooted but timing is important. Hormonal treatment is necessary. Percentages ranged from 60 to 90% depending on sampling time and hormonal strength.

NATIVE HABITAT: Nova Scotia to Minnesota, south along the mountains to Alabama and Georgia. Driving to the mountains from Athens (~700' elevation), *T. canadensis* starts to appear about 1,000 to 1,200' elevation and becomes common above 2,000'. Abundant on slopes, mountain sides, almost anywhere drainage is reasonable. Introduced about 1736.

RELATED SPECIES:

Tsuga chinensis (Franch.) E. Pritz. — Chinese Hemlock
(tsū'ga chi-nen'sis)

LEAVES: Linear, 1/2 to 1" long, 1/12 to 1/8" wide, emarginate, glossy dark green above and slightly grooved, broad whitish bands below.

STEM: Yellow-brown, pubescent.

Tsuga chinensis, Chinese Hemlock, is a large tree growing over 100' in the wild. The most inspiring news I have heard concerned the woolly adelgid resistance of the species. Considerable interest in the middle Atlantic and northeastern states as a potential alternative to *T. canadensis*. Several United States specialty nurseries offer the species. Tested in Athens and, although it survived, simply never thrived. The ovoid cones are 1/2 to 1" long, lustrous yellowish brown, scales orbicular with beveled margin. Central and western China, Taiwan. Introduced 1902 by E.H. Wilson. Zone 5 to 7.

Tsuga diversifolia (Maxim.) Mast. — Northern Japanese Hemlock
(tsū'ga dī-vēr-si-fō'li-a)

LEAVES: Densely arranged, generally shorter and more densely borne than *T. canadensis*, 1/4 to 5/8" long, 1/10" wide, distinctly notched at the apex, margins entire, glossy dark green and furrowed above, with two clearly defined chalk white bands of stomata below.

STEM: Distinctly hairy.

Tsuga diversifolia, Northern Japanese Hemlock, is a graceful, pyramidal tree that makes an excellent specimen in the landscape. Plant is broad pyramidal and gracefully branched. The branches are reddish brown, pubescent, while those of ***Tsuga sieboldii*** Carr., (tsū'ga sē-bōl'dē-ī), Southern Japanese Hemlock, are glabrous, grayish to yellowish brown. *Tsuga sieboldii* is shrub-like and irregular as I know it in cultivation. The egg-shaped cones of *T. sieboldii* are 3/4 to 1" long, shiny yellow buff brown with scales vertically ribbed and incurved. Cones of *T. diversifolia* are ovoid, 3/4 to 1" long, dark brown, scales flat and striated. Cones on Hillier tree, smaller, 1/2 to 3/4" long, ovoid. The finest plants of *T. diversifolia* I have seen were at Millcreek Valley Park, Youngstown, OH and based on their beauty and performance would have no trouble recommending the tree for general landscape use. Average landscape height would approximate 35 to 60'. On a tour of Ireland, experienced *T. diversifolia*, 30 to 40' high, gracefully arching, pyramidal habit, and lustrous dark green needles at Mt. Congreve. A specimen of *T. diversifolia* called 'Emerald Ice' grows on the UMaine campus, Orono. Just the fact that it grows in Maine is amazing! Neither species is common in commerce and with so many excellent forms of *T. canadensis* it is difficult to compete. *Tsuga sieboldii* is native to the moist mountains of Southern Japan. Beautiful about 18' plant at the Raulston. Introduced 1850. Zone 5 to 6. *Tsuga diversifolia* grows near the timberline in Japan. Introduced 1861. Zone (4)5 to 6.

Tsuga heterophylla (Raf.) Sarg. — Western Hemlock
(tsū'ga het-ēr-ō-fil'a)

LEAVES: More or less in 2 ranks (rows), although set all around the stems, 1/4 to 3/4" long, 1/20 to 1/16" wide, rounded at apex, entire, shining dark green and grooved above, broad white bands below.

STEM: With long pale pubescence when young, carrying pubescence into 5th and 6th years.

Tsuga heterophylla, Western Hemlock, is a handsome tall tree with a narrow pyramidal crown, slightly semi-pendulous branchlets and fine-textured, dark green needles with two whitish bands below. Tri-national champions are 172' by 65', 195' by 47', and 237' by 67', all in Olympic National Park, WA. I have seen the tree in Washington, Vancouver, BC and all over Europe and it makes an imposing specimen. The 3/4 to 1" long cones are sessile but hang from the branch tips. Best growth occurs in a moisture-laden atmosphere and at cooler summer temperatures than are found in the eastern United States. The stems are yellow-brown, change to dark red-brown and remain pubescent for 5 to 6 years. Red-brown bark develops deep, scaly ridges and is up to 1 1/2" thick. 'Thorsens Weeping' with emerald green foliage and procumbent branches is listed. Additional cultivars are known. Southern Alaska to Idaho and California. Introduced 1851. Zone 6 to ?

Tsuga mertensiana (Bong.) Carr. — Mountain Hemlock
(tsū'ga mēr-ten'si-ā-na)

LEAVES: Radially spreading, 1/3 to 3/4"(1") long, 1/16" wide, obtuse apex, convex above and often keeled, almost round in cross section, entire, stomatal lines on both surfaces resulting in a blue-green to gray-green color.

Tsuga mertensiana, Mountain Hemlock, is possibly the least adaptable of the hemlocks treated herein. In the wild, a tree 50 to 90' high, but much less under cultivation. National champion is 183' by 65' in Prince William Sound. Forms a slender pyramidal outline with slender pendent branches. Cones, 1 to 3" long and wide, purple-green maturing brown, are slightly pendent. Bark is dark red-brown with deep, narrow ridges. Prefers cool, moist root run and cooler air temperatures. Have seen plants in the Netherlands that appeared native they were so robust. Bonnie and I were hiking in the Mt. Rainer National Park and saw this species in its myriad colors. Almost always more narrow and slender than *T. heterophylla* which may be related to its ability to shed snow loads. Foliage color is distinctly different than other species and 'Argentea', 'Blue Star', 'Bumps Blue', 'Elizabeth', 'Glauc', 'Glauc Nana', 'Horstmann', 'Mt. Hood Blue', and 'Quartz Mountain' are more silvery or blue-needled forms. 'Blue Star', as I witnessed, was as handsome as the blue forms of *Picea pungens* var. *glauca*. *Tsuga xjeffreyi* (Henry) Henry embodies hybrids between *T. mertensiana* and *T. heterophylla*, although GRIN treats it as a synonym of *T. heterophylla*. *Tsuga mertensiana* is, unfortunately, not a tree for the eastern United States. Highly susceptible to *Phytophthora* root rots in controlled studies; see *Tree Planters Notes* 40(1):15–18 (1989). Southern Alaska to northern Montana, Idaho and California. Introduced 1854. Zone 5 to ?

Tsuga caroliniana Engelm. — Carolina Hemlock

(tsū'ga ka-rō-lin-ē-ā'na)

LEAVES: Radiating around the stem, linear, 1/4 to 3/4" long, about 1/12" wide, apex blunt or slightly notched, glossy green above, with 2 distinct white bands beneath, margins entire.

BUDS: Ovoid to roundish, apex blunt, pubescent.

STEM: Light orangish to reddish brown when young, finely pubescent or nearly glabrous.

SIZE: 45 to 60' in height by 20 to 25' spread; national champion is 98' by 36' in Montgomery Co., VA.

HARDINESS: Zone 4 to 7.

HABIT: Airy, spiry-topped tree with a tapering trunk and short, stout, often pendulous branches forming a handsome, evenly pyramidal head; often more compact and of darker green color than *T. canadensis*; handsome in the wild as it grows on the side of the mountains, tall and stately, surveying the valleys below.

RATE: Slow to medium, not as fast as *T. canadensis*.

TEXTURE: Medium.

BARK: Reddish brown, deeply fissured, scaly.

LEAF COLOR: Glossy green above, with two silvery bands below.

FLOWERS: Monoecious, inconspicuous.

FRUIT: Cones short-stalked to sessile, oblong-cylindrical, 1 to 1 1/2" long, 1" wide, scales radiating out from center.

CULTURE: Transplants well balled-and-burlapped if root pruned; needs moist, well-drained soils; partially shaded, sheltered exposure and will not tolerate droughty conditions.

DISEASES AND INSECTS: Ambrosia beetle has been reported on this species, also susceptible to woolly adelgid.

LANDSCAPE VALUE: Described as tolerating adverse conditions better than *T. canadensis*, and probably as good a landscape plant but not as well-known; tends to be more stiff and rigid although I have seen plants that rival the best *T. canadensis*; qualities may be overstated for it has never found its way into the mainstream. For all the chatter about durability, there is no evidence of same in landscapes. Best landscape deployment yet observed is a 12' high, feathery hedge at the North Carolina Arboretum, Asheville.

CULTIVARS: Several are noted in the literature.

'Arnold Pyramid'—Pyramidal, dense, with a rounded top, 25 to 35' high.

'Compacta'—Dwarf, low growing and very dense, wider than high.

'Greenbrier'—Weeping, 40-year-old tree is 5' high, 20' wide, good green needle color.

'La Bar Weeping'—Prostrate if allowed to its own devices, weeping if staked, handsome foliage; 2 1/2' by 5 to 6'.

PROPAGATION: Same as for *T. canadensis*.

ADDITIONAL NOTES: Easily separable from *T. canadensis* by the way the foliage radiates around the stem forming a bottlebrush-like effect, the larger cones and entire needles.

NATIVE HABITAT: Southeastern United States (southwestern Virginia to northern Georgia in the Blue Ridge Mountains). Large trees grow around the rim of Tallulah Gorge, Georgia, in well-drained situations. I suspect in heavy, wet soils, the species would prove the worst for wear. Introduced 1881.

Ulmus americana L. — American Elm, also known as White, Gray, Water, or Swamp Elm
(ul'mus a-mer-i-kā'na)

FAMILY: Ulmaceae

LEAVES: Alternate, simple, ovate-oblong, 3 to 6" long, 1 to 3" wide, acuminate, unequal at base, doubly serrate, lustrous dark green, glabrous and rough or smooth above, pubescent or nearly glabrous beneath, lateral veins crowded, 13 to 18 pairs, straight, running out to teeth; petiole—1/4 to 1/3" long.

BUDS: Terminal—absent; laterals—imbricate, ovate-conical, pointed, 1/4" long, slightly flattened and more or less appressed against the stem, light reddish brown, smooth and shining or slightly pale-downy; flower buds stouter, obovate, appearing as if stalked, scales generally with darker and more or less hairy-edged margins.

STEM: Slender, round, red-brown, pubescent at first, becoming glabrous (sometimes maintaining pubescence); leaf scars with 3 distinct bundle traces that result in a "cat-face" configuration.

SIZE: 60 to 80' with a spread of 1/2 to 2/3's the height, may grow larger; national champion is 136' by 85' in Baltimore County, MD.

HARDINESS: Zone 3 to 9.

HABIT: Three distinct habits are recognized and include the vase-shaped form in which the trunk divides into several erect limbs strongly arched above and terminating in numerous slender often pendulous branchlets, the whole tree a picture of great beauty and symmetry; a form with more widely spreading, less arching branches, often called the "oak-form"; and a narrow form with branchlets clothing the entire trunk.

RATE: Medium to fast, 10 to 12' in 5 years; this rate of growth is common for many elms.

BARK: Dark gray with broad, deep, intersecting ridges, or often scaly; outer bark in cross section shows layers of a whitish-buff color alternating with thicker dark layers.

LEAF COLOR: Lustrous dark green in summer, yellow in fall; great variation in intensity of fall coloration.

FLOWERS: Perfect, greenish red, in fascicles of 3 or 4, March, usually late February in Athens, interesting but not showy.

FRUIT: Rounded, notched, disc-shaped samara, 1/2" long, maturing in May through June, not ornamental, greenish, but may have reddish tinge, fringed with hairs.

CULTURE: Easily transplanted because of shallow, fibrous, wide-spreading, gross feeding root system; prefers rich, moist soils but grows well under a variety of conditions; in the wild the tree is a common inhabitant of wet flats where standing water may accumulate in the spring and fall; prune in fall; pH tolerant; shows good soil salt tolerance.

DISEASES AND INSECTS: The elms are, unfortunately, subject to many pests and I have often wondered why they have been treated as royalty when they are so fallible. Many of the pests are devastating and control measures are simply not effective or available. The following list should provide an idea of the potential problems which may beset "your" elm. Wetwood, *Erwinia mimipressuralis*, is a bacterial disease which appears as a wilt, branch dieback, and internal and external fluxing of elms. A pipe is often placed in the tree to relieve the tremendous gas pressure that builds up; no control known. Cankers (at least 8 species cause cankers and dieback of stems and branches), Dutch elm disease (*Ophiostoma novo-ulmi*, devastating and essentially uncontrollable), bleeding canker, leaf curl, leaf spots (there are so many fungi that cause leaf spots that only an expert can distinguish one from another), bacterial leaf spot (*Pseudomonas syringae*), bacterial leaf scorch (*Xylella fastidiosa*), powdery mildews, *Cephalosporium* wilt, *Verticillium* wilt, woody decay, phloem necrosis (apparently caused by a mycoplasma), mosaic, scorch, woolly apple aphid, elm leaf curl aphid, Japanese beetle, smaller European elm bark beetle, elm borer, spring canker worms, fall cankerworms, elm cockscomb gall, dogwood twig borer, elm leaf miner, elm leaf beetle, gypsy moth, leopard moth borer, white marked tussock moth, elm calligrapha, mites and scales (many species infest elms). Many studies evaluating Dutch elm disease resistance in selected clones of American Elm and other species. *J. Environ. Hort.* 13(3):126–128 (1995) reported that 'American Liberty', 'Princeton' and 4 other clones showed relatively high Dutch elm disease resistance in controlled inoculations. Another study, *J. Environ. Hort.* 14(3):150–154 (1996), reported growth and response to Dutch elm disease among advanced generation progenies and clones of elms. Reasonable checklist of *Ulmus* maladies on the American Phytopathological Society website, www.aspn.org. I counted 47 miscreants.

LANDSCAPE VALUE: At one time extensively used as a street and large lawn tree. The streets of the New England and Midwestern towns and cities were arched with this tree but the Dutch elm disease killed many of the trees. People somehow have the notion that all the American Elms were destroyed. This is by no means true and many cities have extensive maintenance programs. Having gone to school in Massachusetts I can appreciate the legacy of these elms and the pride that people take in them. The elms, unfortunately, have not stopped dying. I continue to witness venerable specimens succumb to Dutch elm disease. I can remember a fine planting of 'Ascendens' on the Amherst College campus which as a graduate student at the University of Massachusetts from 1969–1972 I photographed frequently. They are now gone. Urbana, IL was called the city of the elms and the Illinois campus was extensively planted. There may be no American Elms left for most of the remaining ones had died during my seven years on campus. In some respects it seems only a matter of time before Dutch elm disease wins. There are fine, established plantings on many campuses that are being maintained by systematic spray programs. Eventually because of age and/or disease these will pass and the search for a suitable substitute will continue. In my opinion, there is no perfect substitute (presently) for the American Elm. See *Arnoldia* 42(2) (1982), for a good discussion of the American Elm.

CULTIVARS: Many cultivars were named; most succumbed to Dutch elm disease and are no longer extant.

'Ascendens'—Upright form, 4 to 5 times as tall as wide, branches high up on trunk.

'Augustine'—Fast growing, columnar form, branched to ground, 3 times as high as broad.

'Creole Queen'—Selection from near New Orleans, LA by Steve Sanchez; witnessed at Select Trees, GA, tight branching habit, upright form similar to young 'Princeton' elm; do not know absolute degree of Dutch elm resistance; own-root production; from Tree Introductions, Inc., Athens, GA.

'Delaware #2'—Highly resistant to Dutch elm disease, vigorous with a broad spreading crown, 70 to 80' high, introduced by Nursery Crops Research Laboratory, Delaware, OH.

'Independence' (PP 6,227)—One of the American Liberty elms that was patented.

'Jackson'—Selection out of Wichita, KA, showing no Dutch elm disease damage at +50 years of age, this is the White Oak form covering over 1/2 acre.

'Jefferson'—Vase-shaped with arching limbs; green summer foliage, changing to yellow in fall; 50' by 50'; resistant to Dutch elm disease; National Park Service introduction.

'Lake City'—Upright form, wide at top and narrow at base, however, not the typical vase-shaped form.

'Liberty' ('American Liberty')—Described as Dutch elm disease resistant by Elm Research Institute, Harrisville, NH 03450, however, the plants constitute a grex of 6 clones, probably 5 now extant, that were released via the University of Wisconsin; their Dutch elm disease resistance is not as high as that of 'Jefferson', 'Princeton', 'Valley Forge' and 'New Harmony'; trees were noted as highly susceptible to elm yellows (phloem necrosis) in New York, see *J. Arboriculture* 20:176–189 (1994).

'Littleford'—Columnar, 3 times as high as wide.

'Moline'—Good, rugged, moderately vase-shaped form; one of the last of the American Elms to succumb to Dutch elm disease on the Illinois campus.

'New Harmony'—Broadly vase-shaped crown, main trunk divides nearly 30' from ground into a few erect and strongly arched limbs terminating in numerous, slender, often drooping branches; parent tree was 68' by 72'; respectable tolerance to Dutch elm disease, reported tolerance one-fifth that of 'Valley Forge'; discovered in Clark County, OH, U.S. National Arboretum introduction, released in 1995.

Prairie Expedition™ ('Lewis and Clark')—A Dutch elm disease resistant cultivar released in 2004 by Dr. Dale Herman, NDSU in celebration of the Lewis and Clark expedition; photo of tree shows classical American elm habit; should be a good option for colder zones.

'Princeton'—Large leathery foliage, vigorous, and good resistance to elm leaf beetle (foliage feeder) and Dutch elm disease; became intrigued with this selection during my 1991 sabbatical at the Arnold; named in 1922 and introduced by Princeton Nursery; it has demonstrated moderate to high resistance to the disease; several nurseries now produce the tree; grows exceptionally fast under managed nursery care; good early vase-shaped form, much better than 'Valley Forge'; becoming more available but still shows susceptibility to Dutch elm disease; Vincent Simeone, Director, Planting Fields Arboretum, New York, reported Dutch elm disease infected trees that had to be removed.

'Triploid Elm'—Natural hybrid found on National Mall, Washington, DC; highly resistant to Dutch elm disease; vase-shaped habit of American Elm but not as graceful; see *Can. J. Forest Res.* 24(4):647–653 (1994).

'Valley Forge'—Classic American Elm shape, upright-arching, broadly V-shaped branch structure with a full, dense canopy; 12-year-old propagules were 26' by 30', estimated 60 to 70' by 60' to 70'; controlled screenings for Dutch elm disease resistance showed 'Valley Forge' was the most tolerant; released in 1995 by U.S. National Arboretum; a floppy grower as a young tree and requires staking; leaves shiny dark green based on young budded plants at Schmidt's; witnessed a 20' by 20' tree on the Swarthmore Campus in 2005 with typical American elm habit and extended, ascending branches.

'Washington'—Selected for crown resistance to Dutch elm disease; good glossy foliage; 70 to 80' high; selected by Dr. Horace V. Webster, former plant pathologist, National Park Service, Washington, DC.

PROPAGATION: Seeds of some lots show dormancy and should be stratified at 41°F for 60 to 90 days in moist medium although some seeds do not require any treatment. In the long run it is probably safer to stratify. Cuttings can be rooted; those taken in early June rooted 94% with IBA treatment. Strong juvenility effect is evident with *U. americana* cuttings collected from stump sprouts (6 to 7 1/2' or 1' from ground) and a mature tree which rooted 64, 83, and 38%, respectively. See *HortScience* 10:615 (1975).

ADDITIONAL NOTES: The extensive use of one tree such as the American Elm is an example of foolhardy landscaping. The tree is tremendously ornamental and was overplanted. The diseases caught up with the tree and the results were disastrous. Unfortunately, people do not seem to learn by their mistakes and Honeylocust, Bradford Pear, Green Ash, Red Maple, and Planetree are being used in wholesale fashion for cities, residences and about everywhere. I strongly urge a diversified tree planting program encompassing many different species and cultivars.

I receive many queries about what to substitute for the American Elm. Unfortunately, there is nothing but an American Elm. The *more resistant* clones that have hard disease resistant data ('Valley Forge', 'New Harmony') or longevity ('Princeton', 'Delaware #2') to support them are worthy of use. The American Liberty or Liberty series is not as resistant as the above and their use should be tempered. A few words of recognition are directed to Dr. Alden M. Townsend, now retired Research Geneticist, U.S. National Arboretum, who has worked so diligently toward breeding and selection of elms, maples, and other treasures. Denny is a careful scientist and thoroughly tests the possible introductions. 'Valley Forge' and 'New Harmony' have been given tremendous press and represent the best Dutch elm disease germplasm for American landscapes.

My advocacy for *Ulmus parvifolia*, Chinese Elm, has resulted in new selections (Allée®, Athena®, 'Burgundy', 'Milliken') that will help to partially fill the American Elm void. Certainly the late John Pair, Kansas State University, made superior selections [see *Nursery Management and Production* 12(9):14–15, 65–67 (1996)]. 'Emerald Prairie' is one of John's introductions. In addition, Earl Cully, Heritage Trees, Jacksonville, IL is introducing a more cold hardy selection, 'Zettler'. The Morton Arboretum, largely through the work of Dr. George Ware, introduced a number of Asiatic elm selections. These are detailed in *Nursery Manager* 9(5):32, 34–35 (1993), and 9(6):30–33 (1993). Santamour and Bentz, *J. Arboriculture* 21(3):122–131 (1995), provide a checklist of all elm cultivars introduced since 1964 and complete listings for *U. americana*, *U. japonica*, *U. parvifolia*, *U. pumila*, *U. wilsoniana*, and all cultivars of putative hybrids in which at least one parent was native to North America.

NATIVE HABITAT: Newfoundland to Florida, west to the foot of the Rockies. Naturally found in bottomlands, floodplains, swamp forests, ravines and rich woodlands. Introduced 1752.

RELATED SPECIES:

***Ulmus rubra* Muhl.** — Slippery Elm, Red Elm
(ul'mus rū'bra)

LEAVES: Alternate, simple, obovate to oblong, 4 to 8" long, about half as wide, long acuminate, very unequal at base, doubly serrate, tinged bronze-red when emerging, dark green and very rough above (scabrous), densely pubescent beneath; petiole—1/4 to 1/3" long.

BUDS: Terminal—absent, laterals about 1/4" long, dark brown, nearly black at tips of scales, long rusty hairs at tip of bud; flower buds more or less spherical.

STEM: Rather stout, light grayish brown, pubescent, roughened by numerous raised lenticels, strongly and characteristically mucilaginous if chewed.

FRUIT: Orbicular or obovate, 1/3 to 3/4" long samara, slightly notched at apex, center covered with red-brown hairs, glabrous elsewhere.

Ulmus rubra, Slippery Elm, is a close cousin of the American Elm and often goes under the names Red, Gras, or Moose Elm. The tree grows 40 to 60' high with a somewhat vase-shaped habit but the branchlets are more ascending (upright) than those of American Elm. Co-national champions are 103' by 93' in Frederick, MD, and 130' by 90' in Clay, KY. The ornamental value is limited and this species actually becomes a weed as it tends to infest unkempt shrub borders, hedges, fence rows, and other idle ground. Prefers moist, rich, bottomland soils but also grows on dry, limestone soils. The name "Slippery" developed because of the mucilaginous inner bark which was chewed by the pioneers to quench thirst. It is susceptible to Dutch elm disease, but not to the degree of *U. americana*. Native from Quebec to Florida, west to the Dakotas and Texas covering much of the same range as *U. americana*. Cultivated 1830. Zone 3 to 9.

*Ulmus thomasi**Ulmus serotina*

Two other native elm species worth mentioning include: *Ulmus thomasi* Sarg., (ul'mus tom-as'ē-i), Rock or Cork Elm, and *Ulmus serotina* Sarg., (ul'mus ser-ot'i-na), September or Red Elm. The former has an oblong crown and the trunk usually remains unbranched. It is found on dry gravelly uplands and rocky slopes but attains its best development in rich bottomland soils. The wood is heavy, hard and tough. The finest of all woods; hence the name Rock Elm. The wood was used in the construction of automobile bodies and refrigerators. It is now used for furniture, agricultural implements, hockey sticks, ax handles, and other items which require a wood which will withstand strains and shocks. National champion is 100' by 85' in Cass County, MI. Native from Quebec to Tennessee, west to Nebraska. Introduced 1875. Zone 3 to 7. The latter elm, *U. serotina*, is a southern species ranging from Kentucky to Alabama, to north Georgia, southern Illinois to eastern Oklahoma. Flowers in late summer—early fall, the fruits ciliate with silver-white pubescence. National champion 83' by 77' in Davidson, TN. Cultivated 1903. Zone 5 to 8. Both are susceptible to Dutch elm disease.

Ulmus alata Michx. — Winged Elm (ul'mus a-lā'ta)

LEAVES: Alternate, simple, ovate-oblong to oblong-lanceolate, 1 1/4 to 2 1/2" long, half as wide, acute or acuminate, unequal, doubly serrate, leathery, dark green and glabrous above, with axillary tufts below; petiole—1/10" long.

BUDS: Almost like miniature versions of *U. americana*—imbricate, reddish brown.

STEM: Gray to brown, glabrous, slender with two opposite corky wings but not always present; pronounced on young vigorous shoots.

Ulmus alata is a medium-sized, 30 to 40' (50 to 60') high tree with spreading branches that form a round-topped, oblong head. National champion is 114' by 91' in Aiken, SC. It is common in the South and especially noticeable for the 2 broad, opposite, corky wings that develop on the branches. The dark green, 1 1/4 to 2 1/2" long leaves may turn dull yellow in fall but are often infected with powdery mildew and remind of a Common Lilac in its best mildew condition. The species is much larger growing than I realized and trees 60 to 70' are common in Athens and vicinity. In their finest forms, they approach American Elm in outline but are finer and more graceful in texture. Fall color has been beautiful yellow on occasion. Leaves abscise early. The mildew susceptibility is a variable trait for some trees approach whiteness while others are not affected. The greenish red flowers open in mid to late February (Athens) and are followed by oval, 1/3" long, villous samaras with 2 inward curving beaks at apex. 'Lace Parasol' is a stiffly weeping form, 10' by 15', with handsome corky branches, leaves similar to species, one of the late J.C. Raulston's favorite plants, introduced through the JC Raulston Arboretum. Parent plant transplanted from its Chapel Hill original site to the Raulston where it is now 20' by 30', more beautiful without leaves because of the habit and corky wings. A beauty and one of the signature plants in the Raulston Arboretum. Discovered by Dr. Charles Keith and shared with the Raulston Arboretum. Virginia to Florida, west to Illinois, Oklahoma and Texas. Introduced 1820. Zone 6 to 9.

Ulmus glabra Huds. — Scotch Elm, Wych Elm

(ul'mus glā'bra)

LEAVES: Alternate, simple, oblong-ovate to elliptic or obovate, 3 to 7" long, 1 1/2 to 4" wide, abruptly acuminate, occasionally 3-lobed at apex, very unequal at base, sharply and double serrate, dark green and scabrous above, pubescent beneath, rarely nearly glabrous, 14 to 20 vein pairs; petiole—1/8 to 1/4" long, pubescent.

BUDS: Imbricate, terminal—absent, laterals—1/4" long, dark chestnut brown to brown-black with hispid bud scales.

STEM: Dark gray-brown with bristle-like pubescence, distinctly hairy.

Ulmus glabra is a large, massive, rather open tree growing from 80 to 100' with a spread of 50 to 70'. The foliage is dark green in summer and green to yellow to brown in fall. The species is not stellar as I witnessed it, but the cultivars 'Camperdownii' and 'Pendula' are worthwhile. The former is a round-headed, pendulous-branched type that is usually grafted about 6 to 7' high on the understock, while the latter, although often confused with 'Camperdownii', is a flat-topped tree with horizontal branches and pendulous branchlets. The origin of 'Camperdownii' is interesting for it apparently originated as a seedling and was discovered creeping along the ground at Camperdown House, near Dundee, Scotland in the first half of the 19th century. On a scouting trip for our Scottish garden tour, Al Armitage and I took a side trip to Dundee to find the original tree. Find we did, the house in a park-like setting and one rather pathetic, snaggle-toothed, weeping elm that both of us said could not be the original. The mind conjures great expectations of what something should look like. When that something is found and is not up to concept, then it is easy to dismiss said object as not the original. In short, I was broken-hearted. Camperdown Elm will grow 15 to 25' high, usually wider and is grafted on *U. americana* in the United States and what appears to be *U. minor* in Europe. The bark of Camperdown is somewhat blocky or cross-checked, almost scaly, while the understock is ridged-and-furrowed. I have seen plants of 'Horizontalis' (Tabletop Elm) that were 33' across and no more than 15' high. Hillier, 2002 listed 'Horizontalis' as 'Pendula'. I have seen tremendous crops of fruit on 'Horizontalis' but not on 'Camperdownii'. Many plants labeled as 'Camperdownii' are 'Horizontalis', at least as I have observed them in the United States. I saw the most magnificent planting of 'Horizontalis' near the Cathedral of Notre Dame, Paris. When used properly it makes a rather handsome and eye-catching plant. 'Exoniensis', an upright form with leaves folded along the midrib and clustered, grew 1' per year over a 10-year-period in Kansas tests. Was (still may be) a tree on the Smith College Campus, rather stiff, upright, with coarse branching structure. 'Lutescens' with soft yellow spring leaves, turning yellow-green, is known. 'Nana' is a dense, broad-rounded mound, about 6' high, that I fondly remember from its placement in the rock garden at Edinburgh. Native to northern and central Europe, western Asia. Zone 4 to 6.

Ulmus ×hollandica Mill. — Dutch Elm

(ul'mus hol-lan'di-ka)

Ulmus ×hollandica includes a group of trees which resulted from crossing *U. minor* × *U. glabra* with the progeny supposedly intermediate between the two parents.

Selections have been made from the group.

Quite confused taxonomically and generally of little landscape interest in the United States. I have tried to make sense of the taxonomy of this grex but it is too complex to be

presented in a condensed version. Bean simply lists the old hybrid or pure clones as 'Belgica' (Belgium or Holland);

'Dampieri' (also a golden-leaf form, 'Dampieri Aurea', see under

U. minor; 'Hollandica' (Dutch); 'Smithii' ('Downton'); 'Vegeta' (var. *vegeta*,

'Huntingdon'); all, unfortunately, are susceptible to Dutch elm disease and many splendid specimens have been lost. See *U. minor* text for more cultivars.

Ulmus japonica (Rehder) Sarg. (To accept the GRIN name change to *U. davidiana* var. *japonica* (Sarg. ex Rehd.) Nakai turns my treatments sideways. The line in the taxonomic sand has been drawn and I refuse to cross. See my comments under *U. minor*.) — Japanese Elm
(ul'mus ja-pon'i-ka)

Ulmus japonica, is a beautiful, vase-shaped tree to 100' with dark green, elliptic to obovate, 3 to 5" long, acuminate, doubly serrate, scabrous-surfaced leaves, 12 to 16 vein pairs; petiole—1/5" long, densely pubescent. A magnificent tree, comparable to American Elm in outline, about 80' high, grows next to South College on the University of Massachusetts campus, Amherst. As a student (1969-1972), I walked under its outstretched, leafy boughs and during a visit in July 2006, the tree was still glorious. Many (most) American elms on campus had succumbed. Obviously, there is inherent Dutch elm disease resistance that has been incorporated into selections and hybrids including: Accolade®, 'Cathedral', Danada Charm™, 'Jacan', 'Mitsui Centennial', 'New Horizon', Triumph™, Vanguard™ and possibly others. The Arnold Arboretum had several magnificent trees, although I was not absolutely sure of their trueness-to-type. Steve Bieberich's 'Emerald Sunshine' exactly fits the above foliar profile. Also, the branches of *U. japonica* are densely pubescent, pale yellowish brown. Zone 5 to 7. Japan, northeastern Asia. Introduced 1879.

Ulmus minor Mill. (formerly *Ulmus carpinifolia* Gled.) — Smoothleaf Elm
(ul'mus mi'nor)

LEAVES: Alternate, simple, elliptic to ovate or obovate, 1 1/2 to 4" long, 1 to 2" wide, acuminate, very oblique at base, doubly serrate with about 12 pairs of veins, lustrous dark green and smooth above, glabrous when young, pubescent on veins beneath; petiole—1/4 to 1/2" long, usually pubescent.

BUDS: Imbricate, terminal—absent, laterals—1/8 to 1/4" long, deep brown to black, ovoid, bud scales covered with soft silky pubescence, edges of scales often finely ciliate.

STEM: Brown, slightly pubescent, older branches turning ashy gray.

Ulmus minor is native to Europe, North Africa, and western Europe. The tree will grow 70 to 90' with a straight trunk and slender, ascending branches forming a weakly pyramidal tree. Personally I find the tree attractive but again it is an elm and subject to all the pests although considered intermediate in resistance to Dutch elm disease. The foliage is a lustrous dark green in summer. Zone 5 to 7. The following cultivars are largely hybrids from various breeding programs and include mixed parentage. For lack of a better venue, I also included the Asiatic elm hybrids and selections (exclusive of *U. parvifolia*). See also *U. xhollandica* text. Readers might want to read *Nursery Manager* 9(5):32, 34–35 (1993).

CULTIVARS:

Accolade® ('Morton') (*U. japonica* × *U. wilsoniana*)—American Elm-like, exceedingly glossy dark green foliage, rich golden yellow fall color; very good Dutch elm disease resistance, phloem necrosis resistant, good elm leaf beetle and leaf miner resistance, 80' high in 68 years; a Morton Arboretum introduction, promoted through Chicagoland Grows® program; grown from seed collected at the Arnold Arboretum in 1924, difficult to root from cuttings; Zone 4 to 5; wild and open on young trees at Milliken, not appealing unless pruned to develop an attractive canopy; estimated size 70' by 40 to 50'; the lustrous dark green foliage is impressive; several Georgia tree nurseries have grown this cultivar but not without extensive pruning to make it look like a tree; most have quit production due to excessive manipulations to fashion a salable tree.

- 'Bea Schwarz' (*U. ×hollandica*)—Broad upright crown, 2 to 4" long deep green leaves, 9 to 12 vein pairs; selected around 1935; resistant to Dutch elm disease.
- 'Cathedral' (PP 8,683) (*U. pumila* × *U. japonica*)—More spreading than 'New Horizon' and not as cold hardy; 40 to 50' by 40 to 60'; light to medium green leaves, yellow in fall; high resistance to Dutch elm disease; expect some elm leaf beetle damage; University of Wisconsin introduction; Zone 4 to 7.
- 'Christine Buisman' (*U. ×hollandica*)—Broadly erect form with central leader; 2 to 3 1/4" long leaves, base very oblique; developed by Boskoop Experimental Station around 1945; 60' by 45'; Zone 4; resistant to Dutch elm disease.
- Commendation™ ('Morton Stalwart')—Upright oval habit, 60' by 50'; dark green summer foliage, changing to yellow in fall; rapid-growing; Dutch elm disease and phloem necrosis resistant; complex parentage involving *U. wilsoniana*, *U. pumila*, *U. minor*; wild, flailing, lopsided growth habit at Milliken Arboretum, would prove a difficult sale.
- 'Dampieri' (*U. ×hollandica*)—Narrow conical form; leaves crisped, clustered on short shoots, broad-ovate, 2 to 2 1/2" long, rough and deep green above; originated in Belgium around 1863; somewhat resistant to Dutch elm disease; 'Dampieri Aurea' ('Wredei') has yellow leaves and is slower growing; have seen both in English gardens, Rehder lists it as a *U. minor* selection.
- Danada Charm™ ('Morton Red Tip')—Marked American Elm shape at 30' high; emerging leaves are red, glossy dark green at maturity; expect 60' at maturity; very good Dutch elm disease resistance, phloem necrosis resistance; grown from open-pollinated seed of *Ulmus japonica* × *Ulmus wilsoniana*, a Morton Arboretum introduction, Zone 4 to 5.
- 'Discovery' (PP 10,558) (*U. japonica*)—Distinctly upright, more compact, oval to vase-like habit, forming an arching vase-shaped canopy, 45' by 35'; dark green leaves are 10% smaller than those of 'Freedom' and 'Jacan', yellow fall color; listed as Dutch elm disease, phloem necrosis, elm leaf beetle, and aphid resistant; low seed producer; selected in 1985 from open-pollinated seedlings grown from seeds collected from 20 mature Japanese Elms at the Morden Research Station; listed as hardy to Zone 2.
- Emerald Sunshine®—Thick, credit-card textured leaves, lustrous dark green, densely pubescent, thick hairy stems; upright pyramidal habit on young tree; vigorous grower; witnessed at J.F. Schmidt & Son Co. in August, 2006; may prove quite urban tolerant; listed as *U. propinqua* but that species is merged with *U. japonica*; introduced by Steve Bieberich, Sunshine Farms, Clinton, OK.
- 'Groeneveld' (*U. ×hollandica*)—Like 'Commelin' but with tighter upright habit, dense crown, regular branching, 40 to 50' high; averaged 2'1" per year over a 10 year period in Kansas tests; resistant to wind and Dutch elm disease; from Boskoop Experiment Station, Holland.
- 'Homestead'—Dutch elm disease and phloem necrosis resistant; symmetrical somewhat pyramidal crown to oval-arching; dense dark green foliage may turn straw yellow in fall; rapid growth rate, 12-year-old tree was 36' high and 25' wide, eventually 60' by 35'; considered Zone 5 to 7, although will probably grow in Zone 8; result of complex parentage involving *U. pumila*, *U. ×hollandica*, and *U. minor*, see *HortScience* 19:897–898 (1984) for all details; introduced by Nursery Crops Research Laboratory in 1984; have seen 25' high plants in Cincinnati, has a pleasing form and good foliage, unfortunately, susceptible to elm leaf beetle, true also for 'Pioneer' and 'Urban', this is a better cultivar than 'Pioneer' and 'Urban'.
- 'Jacan'—An *U. japonica* form with excellent hardiness (–30 to –40°F); vase-shaped outline with strong branches; tolerant to Dutch elm disease; 1977 introduction from Morden, Manitoba, Canada; see *Can. J. Plant Sci.* 59:267–268 (1979), Zone 3; pretty good looking tree, 20 to 30' high at Hillier in 1999.
- 'Jacqueline Hillier'—English literature lists this densely branched, slow-growing shrub form, 6' high, as an *U. ×hollandica* type, also listed as *U. ×elegantissima* (*U. glabra* × *U. plottii* Druce); observed 10 to 12' high and wide plants.
- 'Mitsui Centennial' (*U. japonica*)—Fast growth, exceptional hardiness, Dutch elm disease resistance, seedling from Morden.
- 'New Horizon' (PP 8,684) (*U. pumila* × *U. japonica*)—Offers excellent Dutch elm disease resistance and vigor, upright habit, full crown, stress tolerance, and large, dark green leaves; expect some elm leaf beetle damage; University of Wisconsin introduction; Zone 3; unkempt, open, wild, irreverent at Milliken Arboretum.
- 'Patriot' ('Urban' × selection of *U. wilsoniana*)—Upright, stiffly vase-shaped; dark green summer foliage, changing to yellow in fall; may stay narrower than most elms, 43' by 25' in 13 years; high Dutch elm disease resistance; ARS, USDA introduction.
- 'Pendula'—A true cascading weeper that must be staked or top grafted; early habit reminds of 'Cascade Falls' *Taxodium distichum*; vigorous; plant at Rauston Arboretum is beautiful.
- 'Pioneer'—Dutch elm and phloem necrosis resistant; globe-shaped to rounded crown; large dark green leaves with empire-yellow fall color, on occasion good yellow fall color in Spartanburg, SC around late October–early November; dense canopy; grows as rapidly as 'Homestead', result of *U. glabra* × *U. minor* cross; 11-year-old tree is 27' high and 28' wide, predicted 50 to 60' by 50 to 60'; Zone 5 to 7(8); has survived in Minneapolis area as did 'Homestead', but was injured, see *HortScience* 19:900 (1984) for more details; introduced by Nursery Crops Research Laboratory, Delaware, OH in 1984; not a particularly handsome tree with age.

'Prospector' (*U. wilsoniana*)—Offers American Elm-like habit, great vigor, 23' by 21' in 9 years; high resistance to Dutch elm disease and elm leaf beetle; large, 4 to 5" long, dark green leaves that turn yellow in fall; see *HortScience* 26:81–82 (1991) for specifics; I had this cultivar in our evaluation plots where it displayed tremendous vigor and dark green leaves, but was a wild grower; Zone 5 to 7.

'Regal' (PP 5,335)—Dutch elm disease resistant clone that resulted from a cross between 'Commelin' (*U. × hollandica* var. *vegeta* × *U. minor* #1) with N 215 (*U. pumila* × *U. minor* 'Hoersholmiensis'); develops strong central leader and rather open growth habit without the dignity or majesty of good American or Chinese Elms; will probably maintain a pyramidal-oval outline and mature about 50 to 60' by 30'; mature leaves are a dusty spinach green; introduced by University of Wisconsin in 1983; see Smalley and Lester, *HortScience* 18:960–961 (1983) for additional details; should be hardy into Zone 4.

'Sapporo Autumn Gold' (PP 3,780)—Upright vase-shaped form resembling a densely branched American Elm; red tinge to new leaves, glossy dark green at maturity, turning golden in fall; 50 to 60', averaged 2' per year over a 7-year-period in Kansas tests; resistance to the aggressive strain of Dutch elm disease; so-so fall color in Kansas; Zone 3; University of Wisconsin introduction.

'Sarniensis'—Narrowly upright conical in habit; 1 3/4 to 2 1/2" long, glossy dark green leaves; rather good looking form; susceptible to Dutch elm, still relatively common in areas of Middle Atlantic and New England States; 60 to 70'; *U. minor* form.

Triumph™ ('Morton Glossy')—Upright oval to vase-shaped habit with arching branches, 60' by 35 to 40'; glossy dark green summer foliage, changing to yellow in fall; hybrid between Accolade® and Vanguard™; Dutch elm disease resistant; in my opinion, the best habit in early age of the Morton Arboretum elms; performed quite well at Milliken Arboretum; a 15 to 18' tree in the Schmidt Arboretum was somewhat open and irregularly branched; do not see the arching branches in young trees; more upright, yellow fall color at Milliken, late October; leaves fully abscised by early November; early March 2009, wet snow broke branches on one of the Milliken plants.

'Umbraculifera' (*U. minor*)—Usually grafted high on species, forms a single-trunked tree with a densely globose head; leaves smaller than the species, 1 to 2 1/2" long; 20 to 30'.

'Urban'—Result of crossing among *Ulmus × hollandica* var. *vegeta* × *Ulmus minor* × *Ulmus pumila*; resistant to Dutch elm disease; developed by ARS Shade Tree Laboratory, Delaware, OH; grows fast on various soil types, has dark green foliage, and is tolerant of drought, pollution, soil compaction and restricted root space; should make a good tree for heavily urbanized areas; based on my observations, it is not a very handsome tree and is completely lacking in the grace, beauty and dignity of American Elm; I would plant something else before opting for this form; tends toward stiff oblong-rounded head, 50' by 35'; has not received the nursery acceptance of 'Homestead' and 'Pioneer'; grew 2'6" per year over a 7-year-period in Kansas tests.

Vanguard™ ('Morton Plainsman') (*U. japonica* × *U. pumila*)—Was grown from seed of *U. davidiana* var. *japonica* that came from northern China; American Elm shape, 50' high by 45'; waxy lustrous leaves are slightly folded; grows into mid-summer, while Accolade® and Danada Charm™ stop earlier; moderate resistance to elm leaf beetle; tough wood, moderate grower; grown at Morton Arboretum from seed provided by the Morden Experiment Station; a dog at Milliken, leaves much lighter green than Triumph™; likewise at Schmidt Arboretum where it was clearly one of the ugliest trees as I viewed it in late August, 2007; first to leaf out (March 21, 2009) at Milliken, while Accolade®, Commendation™ and Triumph™ were still in tight bud.

'Variegata'—Rather handsome form with white-streaked and -flecked leaves; 30'; appears to be an *U. minor* form.

ADDITIONAL NOTES: In Europe, particularly the Netherlands, elms are common throughout the cities and countryside. In Amsterdam, the canals are lined with elms that I suspect are of hybrid origin. Many were produced by Dutch breeding programs. In addition to those listed above, 'Dodoens', 'Lobel', and 'Plantyn' (all have *U. glabra* 'Exoniensis' as female parent, released in 1975) are at best moderately resistant to the aggressive strain of Dutch elm disease while 'Commelin' (1960 release, susceptible to aggressive strain of fungus) has no resistance. Interestingly, in Dr. Pair's Kansas field tests, 'Commelin' averaged 2'7" per year over a 10-year-period.

Unfortunately, several of the elms have been taxonomically re-jiggered and I do not have a fail-safe roadmap that leads to the final authority. For myself and the reader, I am providing the names per GRIN, but have left the old names in this revision (except in the case of *U. minor*, new for *U. carpinifolia* as this is followed in European literature). *Ulmus japonica* (Sarg. ex Rehd.) Sarg. is *Ulmus davidiana* Planch. var. *japonica* (Sarg. ex Rehd.) Nakai according to GRIN. *Ulmus propinqua* Koidz. and *Ulmus wilsoniana* C.K. Schneid. are lumped into var. *japonica* as presented above. And *Ulmus × hollandica* var. *vegeta* is meshed into *U. × hollandica* by GRIN.

Ulmus parvifolia Jacq. — Chinese Elm, Lacebark Elm

(ul'mus pār-vi-fō'li-a)

LEAVES: Alternate, simple, elliptic to ovate or obovate, 3/4 to 2 1/2" long, 1/3 to 1 1/3" wide, acute or obtusish, unequally rounded at base, simply or nearly simply serrate, lustrous dark green and smooth above, pubescent beneath when young, subcoriaceous at maturity, 10 to 12 vein pairs; petiole—1/4 to 1/2" long.

STEM: Gray-brown, glabrous to slightly pubescent, slender, very fine in texture.

BUDS: Small, 1/10 to 1/8" (perhaps to 1/4") long, brown, smallest buds of any elm, slightly pubescent.

FLOWERS: Easy to recognize because of late flower and fruit dates—August–September (Athens).

BARK: Mottled (rather than ridged-and-furrowed like most elms), exfoliating in irregular patches, exposing lighter bark beneath, trunks sometimes fluted.

SIZE: 40 to 50' high and wide; have seen a 70' high tree that was about 59' wide; was walking the Talladega College campus, Alabama, and in front of the library was a gigantic 60' by 60' specimen.

HARDINESS: Zone (4)5 to 9, hardiness greatly dependant on seed source; 40' high trees in Morton Arboretum; Capiello reported no injury on an accession at Orono, ME.

HABIT: Rather graceful round-headed tree often with pendulous branchlets; some forms are upright-spreading, almost American Elm-like; others broader than tall; much variation in habit with no two seedlings alike.

RATE: Medium to fast depending on moisture and fertility levels; grew 1'6" per year over a 10 year period in Kansas tests.

TEXTURE: Medium-fine throughout the seasons.

BARK: Magnificent and often a beautiful mottled combination of gray, green, orange and brown; variable and selections could be made for superior traits.

LEAF COLOR: Lustrous dark green changing to yellowish and reddish purple in fall; fall color is usually not outstanding but appears to be better on southern grown trees than those I observed in the north; leaves hold late and I have photographed trees in late November in fall color in Athens, GA.

FLOWERS: Inconspicuous, appearing in axillary clusters during August–September, essentially masked by the foliage.

FRUIT: Samara, elliptic-ovate, 1/3" long, glabrous, notched at apex, seed in middle, ripens in September–October, collectable by November in Athens.

CULTURE: Easily transplanted, adaptable to extremes of pH and soil; best growth is achieved in moist, well drained, fertile soils; shows excellent urban soil tolerance and should be considered for urban areas; full sun.

DISEASES AND INSECTS: Shows considerable resistance to Dutch elm disease and also the elm leaf and Japanese beetles; in comparing Siberian Elm, Japanese Zelkova, and this species for elm leaf resistance I have found *U. parvifolia* the best followed by *Zelkova serrata* and *U. pumila* which did not even place.

LANDSCAPE VALUE: Excellent, tough, durable tree for about any situation; do not confuse it with the inferior *U. pumila*, Siberian Elm, which by the nursery trade is often offered as “Chinese” Elm; several authors have suggested the name Lacebark Elm to delineate it from *U. pumila* and provide a suitable description of its most beautiful morphological trait; some of the great gardens of the world consider this a superior tree; Disney World, Orlando, FL., has used the tree extensively throughout the grounds; in my opinion, it has received a bad rap for supposed susceptibility to ice, snow and storm damage; in February, 1979 a devastating ice storm hit Athens and caused extensive damage to pines, Water Oak, Siberian Elm, Silver Maple, and other trees; *U. parvifolia* was not damaged and the Georgia campus contains some of the largest, oldest and finest specimens in the country; but always be careful of absoluteness for I have observed ice injury on seedling trees at Milliken; since the 1990 edition the Chinese elm has risen from its biological grave and many new cultivars have been introduced; nurserymen, landscape architects and gardeners are taking a much closer look at the tree’s attributes rather than treating it as another ELM; the gene pool is large and the variation in habit, leaf quality and hardiness almost unbelievable; some of this genetic variation has been exploited with the introduction of new cultivars; I predict a bright future in the 21st century; indeed, if prophecies do come true, this one has; so many plantspeople and growers assessing *Ulmus parvifolia* germplasm that it gives me the chills just to think about the possibilities; with this species the selection process is about the journey and not the destination; new literature, www.invasive.org, mentions the possibility of invasiveness.

CULTIVARS:

Allée® (‘Emer II’, ‘Emerald Vase’, PP 7,552)—An upright-spreading tree with an outline similar to that of American Elm. It measured 70’ high and 59’ wide in 1990. At 4’ from the soil line the mature tree has a 35” diameter trunk and a 110” circumference. The bark exfoliates in a puzzle-like pattern exposing light gray, slate gray, gray-green and orangy brown colors; it is flecked with burnt orange corkish lenticels. The exfoliation begins at the base of the trunk and continues upward to include upper branches 1 to 2” in diameter. Surface roots also exfoliate. Unlike the typically rounded trunk of the species, the trunk is irregularly fluted. The lustrous rich green foliage is densely borne at the ends of the fine branches, creating a dense canopy. Leaf color and texture are typical of the species. Fall color is subdued yellow, occasionally with a red suffusion. Despite the record drought conditions, no leaf scorch or dieback symptoms occurred. In addition, the parent tree was thriving in an 18’ by 18’ area surrounded by concrete. Allée® is also highly resistant to Dutch elm disease and elm leaf beetle. The leaves are alternate and simple, 3/4 to 2” long and 3/8 to 3/4” wide. They are ovate to slightly obovate, lustrous bright green on the top and gray-green on the bottom. They can be acute or obtuse, and they are oblique, with simple serrations that are slightly more pointed than those on Athena®. The leaves are glabrous on both sides and show 11 to 16 vein pairs. The petioles are 1/8 to 1/4” long, light green and pubescent. The chestnut brown buds are ovoid, imbricate, slightly pubescent, 1/8” long and slightly divergent. During the first year, the stems are fine textured, terete, brown and pubescent. In the second year they turn glabrous and gray brown, with small orangy lenticels. The pith is small, solid and brown. The original tree succumbed to a ferocious wind storm in 2006. Tree is widely planted throughout the Southeast and is a major success story. Early March (2009) heavy, wet snow, 6 to 8” in Athens, caused serious limb breakages. I never noted a problem with ice or snow until this occasion.

Athena® (‘Emer I’, ‘Emerald Isle’, PP 7,551)—A broad-spreading elm with a rounded crown resulting in a pleasing globe-shaped outline. It measures 40’ high and 55’ wide. At 3’ from the soil line, the mature tree has a 30” diameter trunk and an 88” circumference. The bark exfoliates 2’ from the ground in a puzzle-like pattern exposing light gray and gray-green to orangish brown colors. The bark is flecked with orangy brown, corky lenticels. The trunk’s base develops a rough, blocky, gray-black bark. The leathery, lustrous dark green (almost black) foliage is densely borne at the ends of the fine branches, creating a dense canopy. The leaves are more leathery and a darker green than the typical phenotype. Fall coloration is bronze-brown and not really effective. Athena® showed no symptoms of leaf scorch during the 1986–88 summers, which were among the driest on record in the Southeast. Likewise, no stress symptoms in the terrible drought years of 2004 to 2008. The tree is also highly resistant to Dutch elm disease and elm leaf beetle. The leaves are alternate and simple, measuring 1 to 2” long and 1/2 to 7/8” wide. They are ovate to slightly obovate and lustrous dark green, almost black-green on the top and gray-green on the bottom. They are oblique and have simple rounded serrations. They are glabrous on both sides and exhibit 10 to 16 vein pairs. The petioles are 1/8 to 1/4” long, light green and often pubescent. The cultivar’s chestnut brown buds are ovoid, imbricate, slightly pubescent, 1/8” long and slightly divergent. In the first year, the stems are fine textured, terete, brown, and pubescent. By the second year, the stems turn gray-brown and glabrous with small orangy brown lenticels. The pith is small, solid and brown. Athena® (2008) is still standing firm, as beautiful as when it was first selected. Beautiful, broad, mushroom-cloud head. Some early propagation idiosyncracies via tissue culture and John Barbour, Bold Spring Nursery, went back to the original tree and started the process anew via cuttings with the name Athena Classic®.

Bosque® ('UPMTF', PP 11,295)—Central dominant leader with strongly ascending secondary branches, pyramidal shape, and fast growth rate; lustrous dark green leaf, underside flat green, fall color yellow-orange; bark gray-orange to gray-brown; parent tree 18' by 8'; introduced by Tree Introductions, Inc., Athens, GA; original description was off-base (by this author) as the tree had been maimed for cuttings, hence, the size listed above; actual estimate is 40 to 50' by 20 to 30', oval rounded outline; handsome tree and possibly the most lustrous dark green foliage of the cultivars with the exception of Athena®; observed a parking lot planting in Wilmington, NC and the trees were about 25' by 25', upright-spreading, with no inclination to strict upright habit.

'Brea'—Described as having an upright habit and larger leaves than 'Drake', 'True Green', and 'Sempervirens'; apparently, Keeline-Wilcox Nurseries, Inc. in Brea, CA, originally listed 'Brea' in its 1982 winter catalog, according to Green (*Arnoldia* 24:41–80 (1964)), this selection is the same as 'Drake'; also, Monrovia Nursery Co., Azusa, CA, described what seemed to be 'Brea' in its 1952–53 catalog but called the cultivar 'Drake'; are 'Brea' and 'Drake', in fact, the same plant? I have not seen 'Brea' in commerce or at arboreta.

'Burgundy'—Selected from the University of Georgia campus as were Allée® ('Emerald Vase') and Athena® ('Emerald Isle') by Dirr and Richards for outstanding foliage and habit; this form has large, thick, dark green leaves that turn deep burgundy fall coloration; habit is distinctly broad-rounded with uniform branch development and extremely fast growth; parent tree was approximately 8 years old and grew in a barren parking lot island, tree was 18' high and 20' wide, amazingly, the plant was removed after 12 years of biological existence; fortunately, it has been reproduced and planted back on the Georgia campus; the bark has started to develop the exfoliating character and is a rich orangish brown, the characteristic flaking and mixed mottle are also apparent; cuttings root readily and, in 1989, percentages averaged over 90% using 5,000 ppm KIBA, 2 perlite:1 peat medium, and mist; many nurserymen have visited our campus and this tree piqued their aesthetic senses; more open with age and not as well proportioned as Allee®, Athena® and Bosque®; attractive trees, 25 to 30' tall and wide at Milliken Arboretum with graceful habit and the burgundy fall color.

Central Park Splendor™ (formerly 'A. Ross Central Park', 'Aross/Central Park', PP 6,983)—The parent tree was planted in New York's Central Park over 100 years ago. The tree is 59' tall with a trunk that measures a little over 4 1/2' in diameter at breast height. The branching habit is spreading, with strong angular branches that fan out from where the crown originates. The tree has strong wood; rarely do its stems or branches break in a storm. The bark of young trees is dark gray and smooth. The parent tree's bark is light gray to light brown fissured into irregular plates. The mature 1 to 1 3/5" long, elliptical, round-serrated leaves are thick and leathery. They are a lustrous spinach green, turning mimosa yellow in fall. Hardy to Zone 5 and can be used as far north as the New York City area without suffering winter damage. Karnosky reported branch and twig dieback at –20°F; young trees were killed outright at –25°F. Softwood cuttings, 3 to 5" long, root with high frequency in one month. Treat them with 3,000 ppm IBA talc and place them in an equal mix of peat and perlite under mist. The plant grows 2 to 4' high in two growing seasons or between 1 1/2 to 2' per year under typical nursery conditions. Young trees head early in the nursery bed but require pruning to develop crowns at suitable heights. See *HortScience* 23:925–926 (1988).

'D.B. Cole'—Is a little-known selection, appears quite bushy in Georgia tests, may be rounded in outline; from an unknown provenance, selected over 30 years ago by Cole Nursery, Co., Circleville, OH; it has lustrous dark green leaves, tinge of red in fall, exfoliating bark on fluted trunks, found to be resistant to Dutch elm disease and phloem necrosis.

'Drake'—Used in the lower South and California and, according to one source, is probably not hardy below Zone 7. Whitcomb and Hickman reported that 'Drake' was severely injured during the 1983–84 winter in Stillwater, OK, when temperatures fell to –8°F on December 23 and –31°F on January 14. Although 'Drake' is listed as hardy in Zone 6, I find this extremely dubious. 'Drake' offers rich dark green foliage on spreading branches that grow more upright than those of regular evergreen cultivars ('Sempervirens') but still approach a weeping tendency. Leaves emerge early, often in March, and persist late into fall. Young trees in containers develop long arching branches. The tree is more or less evergreen in California and stays evergreen through most winters except when it loses its leaves during unusual cold snaps. This cultivar develops an attractive round-headed form of medium size for lawn and street tree use. Bark exfoliates early and is quite handsome. Trees in Athens are low-branched with bad crotches and several have split and required removal.

'Dynasty'—The result of a controlled cross between two trees of seedling origin at the U.S. National Arboretum. The parent trees were grown from seed from the 1929 introduction PI 92487 from the Forest Experiment Station, Keijo, Japan. 'Dynasty' is distinctly vase-shaped. After 16 years, it grew to 30' high and 30' wide with a 12" trunk diameter at 39" from the ground. Summer leaves and fruits are typical of the species. Fall color has been red in cooler climates, a notable trait since typical fall color is seldom effective. The bark is dark gray on young stems and starts to exfoliate when stem diameters approach

- 2" or greater. Unfortunately, some say that the bark's patchiness does not approach a degree of color contrast that could be considered ornamental. One nurseryman told me that the cultivar's bark does not compare with the bark of Allée® and Athena®. 'Dynasty' is cold hardy in Zone 5 and perhaps lower, but it has not been thoroughly tested under Zone 4 conditions. The cultivar is easily propagated from softwood cuttings using an 8,000 ppm IBA talc formulation, coarse medium, and mist. These factors are important since authors have reported great variation in rooting different clones. See *HortScience* 19:898–899 (1984). There are some gaps in this tree's pedigree and the published accounts do not concur with reality. The tree is rather ugly and certainly the bark is totally disappointing. A 30' tree in the JC Raulston Arboretum is sufficient reason to convince people not to grow or buy this clone. Borders on a boondoggle.
- Easy Street® ('Whit XXX', PP 16,883)—Develops central leader with strong branch angles; strong wood tolerates extreme wind and ice conditions; clean dark green foliage; attractive, exfoliating bark develops on 2 1/2 to 3" diameter trunks; Whitcomb introduction; Keith Warren mentioned it was somewhat loose and open.
- 'Elsmo'—Released by the USDA, Soil Conservation Service, Plant Materials Center, Elsberry, MO as an open-pollinated, seed-propagated cultivar, 'Zettler' and perhaps 'Matthew' are derived from this germplasm.
- 'Emerald Prairie'—Similar to Allee® in form, a strong upright vase; may be better adapted to the heat and dryness of the central plains; excellent exfoliating, orange-brown bark; dark green foliage, best resistance to black leaf spot, *Stegophora ulmea*; introduction from John C. Pair Horticultural Center, Kansas State University, Wichita, KS, see *HortScience* 39:181–182 (2004) for details.
- Everclear® ('BSNUPF', PP 17,655)—The first true fastigate-columnar form of Lacebark Elm; a seedling selection made by John Barbour, Bold Spring Nursery; tree transplanted by the office where it has developed into a 35' by 7 to 8' column of lustrous dark green foliage; branches have remained vertical and tight, not occasionally splaying as in some columnar trees; now (2007) available in commerce; a great addition to the short litany of adaptable trees where room to spread is limited.
- 'Frontier'—Is an USDA introduction with lustrous dark green foliage, red fall color, moderate resistance to elm leaf beetle, handsome vase-shaped growth habit, 27' by 16' in 19 years; estimated 40' by 30' with a broad-oval habit; *U. minor* × *U. parvifolia*, see *HortScience* 26:80–81 (1991); has performed well in Georgia tests but *never* in 15 years developed the red fall color; bark is like *U. minor*, a moderate ridged-and-furrowed texture; habit in Georgia trials was uniform upright vase-shaped; certainly a respectable tree; have seen photos of red fall color.
- Garden City Clone—For lack of a better term I used this handle at the request of the late Dr. John Pair; Kansas champion tree, 60' high, medium green foliage, good bark, no cankers, excellent cold hardness, currently not in production and will receive another name, is this now 'Emerald Prairie'?
- 'Glory'—Strong, upright growth habit, vase-shaped overall outline; withstood heavy ice loads with no damage, good street tree; from the late Arborvillage, Holt, MO.
- 'Golden Ray' ('Golden Rey' according to Santamour and Bentz, named by B. Rey, PP 7,240)—Could be 'Aurea', there seem to be several names for the same tree; I saw the "parent" in Oklahoma, large, wide-spreading, dome-shaped habit, yellow foliage (in mid-September), excellent gray-orange-brown exfoliating bark; Steve Bieberich, Sunshine Farms, Clinton, OK is propagating this clone.
- 'Hallelujah'—Fast-growing selection with excellent foliage and bark detail; survived –35°F without damage; from the late Arborvillage, Holt, MO; leaves larger than usual and still present December 19 at Raulston Arboretum.
- Heritage® ('Zettler', PP 10,846)—Strong, upright growth habit, excellent branching structure, no damage after –28°F; parent tree has not suffered breakage from wind and ice; from Heritage Trees, Jacksonville, IL.
- 'Hope'—Rounded habit, branches ascend then arch at extremities, producing semi-pendent appearance, bright green leaves larger than typical, yellow in fall; excellent gray, green, orange and brown exfoliating bark; 40' by 45'.
- 'Jade Empress'—Rounded habit, lustrous dark green leaves; described as easy to grow; from Head-Lee Nursery, Seneca, SC.
- 'King's Choice' (PP 5,554)—A gentleman walked into my office and introduced himself as Ben King. He said that he knew I liked Chinese Elm, and he wanted me to evaluate his new selection. After considerable discussion, he escorted me to his station wagon and handed me 18, strong, 4 to 6' high liners. King selected the tree from 1,000 Chinese Elms seedlings that were planted at King's Men Tree Farm, Hampstead, MD, in April 1978. The tree had grown at twice the rate of the other seedlings and was saved for evaluation. It grew 22' high and 16' wide in seven years and developed an oval-rounded outline. The patent describes the branching pattern as "a single bole, which divides into laterals at angles greater than 90° above the horizon, which then droops to a canopy silhouette much like [that of] American Elm." A photograph that accompanies the patent description does not clearly show this trait.

The leaves of this selection are up to 2 1/2" long, leathery, semi-glossy and dark green and turn a dull yellow in autumn. After 8 years, the bark had not developed an exfoliating character but had regular vertical fissures. The bark's color is described as grayed orange, which means little until one looks at the Royal Horticultural Society Colour Chart. From the information given in the patent description, this tree may not develop the typical bark of a Chinese Elm until it is much older. Softwood cuttings rooted 90% compared with 60 to 80% for the other Chinese Elms King tested. The hardiness is unknown, but a Zone 6 designation, possibly even 5, is probable. Laboratory hardiness testing indicates tolerance to at least -22°F. Had the opportunity to evaluate this under nursery conditions and several things went awry. First, more than one clone was circulated as 'King's Choice'. This appeared to be a result of a mixup in tissue culture. Second, the clones(?), although fast-growing, were weak-wooded and branches actually broke under nursery production via wind (storm damage). I do not know if it (they) is being produced on a commercial basis.

- 'Matthew'—Selection for extreme cold hardiness from Peter J. White, Earthscapes, Inc., Loveland, OH; upright vase-shaped growth habit, strong branches, early exfoliating bark; survived -30.4°F on January 19, 1994 and was the only elm in the nursery that did not suffer severe dieback; roots readily, named after Mr. White's youngest son; was sent photos of original tree, as described above; bark is early exfoliating and gray, green, orange and brown; good looking form, time will tell about ultimate performance.
- 'Milliken'—The parent tree resides in a grassy field in Spartanburg, SC and reminds of the outline of a White Oak from a distance; parent tree approximately 50' by 40' with dark green foliage; bark is superlative with brown, orange, tan mosaic on 2" diameter branches and the mature trunk; has withstood ice, hurricane force winds, and the ravages of time; extremely uniform outer tracery of fine branches lends a well-tailored profile.
- 'Ohio'—Moderate vase-shaped habit, appears more loose and open than many of the newer clones, 40' high in 28 years; small grass green leaves turn grayish red in fall; reddish purple fruit; exfoliating bark; see *American Nurseryman* 176(12):72 (1992); developed by A.M. Townsend, U.S. National Arboretum.
- 'Pathfinder'—Vase-shaped crown, 36' high and 30' wide after 27 years; glossy, yellow-green leaves, grayed red fall color; red-purple fruit; gray-orange exfoliating bark; see *American Nurseryman* 175(4):42 (1992); developed by A.M. Townsend, U.S. National Arboretum.
- 'Prairie Shade'—Selected from 800 seedlings planted in 1973, researchers initially selected 13, only two of these exhibited good form and were easy to propagate from cuttings; seven-year-old trees propagated from cuttings measure 30' tall and 20' wide, with 8" diameter trunks 6" above the soil line; the habit is upright-spreading; leathery, dark green leaves that are smaller than typical for the species; irregular bark character develops slowly, with only moderate flaking when branches are 2 to 3" in diameter; resistant to anthracnose (*Gnomonia ulmea*) and elm leaf beetle; survived the 1983–84 winter in Stillwater, OK, and no ice or wind damage has occurred; performed well in Lubbock, TX; Guymon, OK; and Dodge City and Manhattan, KS; see *HortScience* 21:162–163 (1986); recent reports from Oklahoma indicate significant susceptibility to anthracnose; pretty much died a commercial death due to fungal susceptibility; interesting how it can be evaluated as disease resistant before release and susceptible after.
- 'Red Fall' ('Red')—Selected by Steve Bieberich for red fall color, dark green summer foliage; small trees are oval; have grown the tree in my Georgia trials; fall color is nonexistent and habit not particularly handsome; talked to originator and he is no longer enthused about this clone.
- 'Sempervirens'—Sometimes listed as a variety, but taxonomic references do not consider this valid; generally the epithet refers to the semi-evergreen to evergreen nature of the foliage; described as a medium-sized, round-headed shade tree with graceful, broad-arching branches that assume a weeping tendency at the ends; leaves are dark green; older trees shed their bark in patches, somewhat like sycamores; this tree, or a reasonable facsimile, is widely grown in California and Florida but is listed as hardy in Zone 6; Hickman and Whitcomb reported severe injury at -8°F and -31°F during the 1983–84 winter in Stillwater, OK, realistically, this tree is hardy in Zone 8 and possibly in Zone 7; apparently 'Sempervirens' is extremely variable in form, which suggests it is seed-grown; appears to have characteristics similar to those of 'Pendens' (forma *pendula*), which Rehder described in 1945 as having long, loosely pendulous branches.
- 'Small Frye'—Perfect mushroom-headed small tree with uniform, dense branching and thickish, lustrous dark green leaves; bark exfoliates in gray, orange, brown patchwork; parent tree 15 to 20 years old, about 18' high, 25' wide; might prove a worthy selection in small landscapes, under utility wires, and in large containers; remarkably uniform and aesthetic habit; no leaf diseases to date; in early stages of evaluation; selected by the author.
- 'State Fair'—Globe-shaped crown with dense foliage and excellent exfoliating bark; selected by Steve Bieberich.

'The Thinker'—An introduction from University of Louisville campus, selected by Mike Hayman for rounded habit, good, dark green foliage and handsome exfoliating bark; probably will not become a commercial reality; named for proximity to statue by Rodin.

'True Green'—More evergreen than 'Sempervirens' or 'Drake' and also less hardy, although listed for Zone 7; at -4°F, the tree was severely injured in Stillwater, OK; develops a graceful, round-headed outline and has small, glossy, deep green leaves; unfortunately, the bark characteristics of 'True Green' are unknown; I have observed older Chinese Elms in California and Florida with semi-evergreen tendencies that developed respectable exfoliating bark, however, there was no way to determine whether the trees were any of the above.

Variegated Form(s)—More than one with some degree of edging, mottling or streaking to the leaves; the best was heavily marked with white, the green more speckled, and the entire tree without reversions; witnessed at Pat McCracken's North Carolina nursery in mid-July; no scorch, necrosis or browning; quite vigorous grower; Pat said difficult to propagate; if someone would crack the nut, gardeners would enjoy a beautiful, variegated, small tree.

Numerous compact, dwarf, and variegated forms are known. The compact forms have long served as bonsai "fodder." Interestingly, 'Frosty' with white-tipped marginal serrations, grows over 20' high; a 15 to 18' high specimen at Hillier, 1999, with lousy bark. 'Catlin' is semi-dwarf, smaller (1/4 to 1/2" long) leaves, may remain evergreen on containerized plants in California, exfoliating bark; 'Chessins' is shrubby to 3', small 1/3" long leaves, variegated; 'Cork Bark' ('Corticiosa') has corky bark, ±20' high and wide; 'Ed Wood' is miniature with tiny leaves, good bonsai material; 'Geisha' has a low habit, creamy young leaves, spotted and speckled, dark green edged with white at maturity; 'Hokkaido' is slow-growing, small leaves, corky bark with age; 'Seiju' is compact, larger leaves than 'Hokkaido' of which it is a sport, corky bark, smaller than 'Catlin', faster than 'Hokkaido'; 'Stone's Dwarf' is a dwarf selection with rough but not corky bark; and 'Yatsubusa' with tiny leaves on corky branches (name also used as a grex to include small-leaved variants suitable for bonsai) are known.

PROPAGATION: If seed is collected fresh (green to greenish brown stage) it germinates in good quantities; however, if left to dry it requires about 2 months cold. I have experimented with the seed and found at least 30 days cold the best prescription for success. Cutting procedures vary with investigator; ideally take cuttings in May–June, 5,000 to 10,000 ppm K-IBA, peat:perlite, mist. See Dirr and Richards, "In search of the perfect Chinese Elm," *American Nurseryman* 169(3):37–49 (1989) for additional propagation information. Tissue culture has been successful; be leery of tissue culture plants for mixups and possible genetic changes have occurred.

ADDITIONAL NOTES: Superior selections have been made for a number of good features. See Dirr, *American Nurseryman* 155(4):75–79 for an in-depth analysis of this and *U. pumila*. The late John Pair, Kansas State, reported it is a good tree for Kansas. John championed this tree for the central Great Plains and had targeted 2 to 3 superior, cold hardy clones. See Dirr and Richards, *Amer. Nurseryman* 169(3):37–49 (1989) for a detailed discussion. I remarked in the previous editions that *Ulmus parvifolia* had a great future. It is obvious from the new cultivars that the future is now and will continue.

NATIVE HABITAT: Northern and central China, Korea, Japan, Taiwan. Introduced 1794.

RELATED SPECIES:

Ulmus crassifolia Nutt., (ul'mus kras-i-fō'li-a), Cedar Elm, like the above,

also flowers and fruits in the fall. It makes a large, 50 to 70' high,

40 to 60' wide tree of oval-rounded outline. National champion is

120' by 68' in Meeman-Shelby State Park, TN. The 1 to 2" long,

1/2 to 1 1/4" wide leaves are lustrous dark green, stiff

and rough (scabrous) to the touch, occasionally borne

subopposite to opposite along the stem. Flowers in

clusters in leaf axils in late summer–early fall. Fruits 1/3"

long, ellipsoidal, tapering at ends, notched, pubescent. The

tree may have possibilities for use from Zone 7 to 9 for it withstands

drought and heavy, infertile soils. It is susceptible to Dutch elm disease, and

elm leaf beetles may cause damage. It is probably not preferable to *U. parvifolia* but does offer a useful

alternative. It is confused with *Ulmus alata*, Winged Elm, but does not have the pronounced corkiness

on the young branches and flowers in fall. Corky wings are often opposite each other along the stem. I

saw numerous specimens in San Antonio, TX. Used as a street and shade tree throughout Southwest.

Mississippi to Arkansas, Texas, northeastern Mexico. Introduced 1876.

Ulmus procera Salisb. — English Elm

(ul'mus prō-sē'ra)

LEAVES: Alternate, simple, ovate or broad-elliptic, 2 to 3 1/2" long, two-third's as wide, short acuminate, oblique, doubly serrate, dark green and scabrous or smooth above, soft pubescent beneath and with axillary tufts of white pubescence, 12 vein pairs; petiole—1/4" long, pubescent.

Ulmus procera has always been a mystery to me for what I was taught as English Elm never jibed with the published description. The answer to the problem is that plants do not read books and teachers should. I encountered a good guide to the elms commonly grown in England at the Chelsea Flower Show. It is entitled "Field Recognition of British Elms," by J. Jobling and A.F. Mitchell, Forestry Commission Booklet 42, available from HMSO, 49 High Holborn, London WC1V 6HB. The book describes the English Elm as broadest near the top, dense, either open umbrella in form or billowing hemispheres; the bark finely fissured into small rectangles, tissues seldom dominantly vertical, dark brown. There are creamy white-marked ('Argenteovariegata') and yellow leaf cultivars but they, like the species, have suffered the ravages of Dutch elm disease and I noticed in the *Hillier Colour Dictionary of Trees and Shrubs* that only one elm is presented with the comment that "the planting of elms has virtually ceased in England." 'Louis van Houtte' with yellow leaves turning yellow-green is attached to this species. Reminded me of 'Wredei Aurea'. A plant in Tony Avent's garden has performed well. 'Silvery Gem' has leaves with cream-white, irregular margins. One of the early introductions to America but difficult to locate. Interestingly, the tree is apparently wholly sterile and it is reproduced from suckers. The validity of this species has been questioned and it has been theorized it may be a hybrid between *U. minor* and *U. glabra* which should place it in the *U. ×hollandica* group(?). Zone 4 to 6. There was a large, stately tree on The Ohio State University campus, about 60 to 70' high.

Ulmus pumila L. — Siberian Elm

(ul'mus pū'mi-la)

LEAVES: Alternate, simple, elliptic to elliptic-lanceolate, 3/4 to 3" long, 1/3 to 1" (1 1/2") wide, acute or acuminate, usually nearly equal at base, nearly simply serrate, with the teeth entire or with only one minute tooth, dark green and smooth above, glabrous beneath or slightly pubescent when young, firm at maturity; petiole—1/12 to 1/4" long, pubescent.

BUDS: Large, globose flower buds, 1/4" long, blackish brown, with ciliate hairs along the edge of bud scales.

STEM: Slender, brittle, very light gray or gray-green, usually glabrous, can be slightly hairy, roughened by lenticellar projections.

FRUIT: Circular or rather obovate samara, 1/2" across, seed almost centered, deeply notched at the top (apex).

Ulmus pumila is a 50 to 70' high tree with a spread 3/4's to equal the height. Co-national champions are 86' by 128' in Londonderry, OH and 85' by 99' in Grand Junction, CO. The habit is rather open, with several large ascending branches with flexible, breakable, pendulous branchlets. The growth is fast and the wood brittle. The tree grows under any kind of conditions. The foliage is dark green and loved by insects. Laboratory feeding study, *J. Environ. Hort.* 12(4):231–235 (1994), showed that *U. pumila* or any hybrid with it as a parent were fodder for the elm leaf beetle. Resistant to Dutch elm disease and phloem necrosis. A poor ornamental tree that does not deserve to be planted anywhere! I have seen whole streets and cemeteries planted with this species. The initial growth is fast but the ensuing branch breakage, messiness, and lack of ornamental assets appalling. One of, if not, the world's worst trees.

Several cultivars have been introduced which would seem to have preference over the species. They include:

'Chinkota'—A cold hardy, seed-propagated line introduced by South Dakota State University.

'Coolshade'—Resistant to breakage in ice storms compared to species; *U. pumila* × *U. rubra*, introduced by Sarcoxie Nursery, Sarcoxie, MO in 1951.

'Dropmore'—Fast-growing form with small neat foliage, hardy in Dropmore, Manitoba, Canada; original selection made by Dr. Frank Skinner; Santamour and Bentz propose name to encompass 'Chinkota', 'Harbin', 'Harbin Strain', and 'Manchu'.

'Hamburg Hybrid'—Stronger wooded than species, fast growing, 4 to 6' per year, *U. americana* × *U. pumila*.

'Improved Coolshade' (PP 1,747)—Fast-growing, uniform habit, hardy, drought resistant and resistant to breakage from wind and ice; *U. pumila* × *U. rubra*.

'Lincoln' (PP 5,015)—Dark green leaves, hold into autumn, respectable branching, resistant to Dutch elm disease, 50' by 40'; Zone 3; *U. pumila* × *U. rubra*.

'Mr. Buzz'—Selection by former Westerveldt Tree Co. (now Plantation Trees), Selma, AL for dense crown, dark green foliage, and vigorous growth; have seen photographs and looks too good to be true, probably is no longer in cultivation.

'Pendula'—Pendulous branches; witnessed in late July at Architectural Trees, Bahama, NC: reasonably ugly but decidedly weeping; fun for weeping tree collector.

The principal attribute is for breeding Dutch elm disease resistance into hybrids like 'Regal', 'Urban', and others. I grew up with the species in the Midwest and fretted constantly about the potential for brain damage engineered by cascading branches. Upon arrival in Athens, I thought the blight was removed but, alas, the tree appeared with the same vengeance. Interestingly, in my 29 years in Athens, several large campus and city specimens have transpired. I have noticed tremendous elm leaf beetle damage; more than I remember from the Midwest. Some of the resistance is evident for a tree next to the University's agronomy greenhouses remained green into fall while others assume a skeletonized gray-brown. I may cut it (the good one) down before a breeder tunes in. How can I forget a September 1992 trip with Mike Glenn and John Barbour to Oklahoma where Steve Bieberich showed us the countryside? Most unforgettable was Woodward, OK where Siberian Elm was the tree of reckoning. The trip was in early September and by that time the elm leaf beetles had created a brown leafy haze. My question: can brown leaves photosynthesize? Native to eastern Siberia, northern China, Manchuria, Korea and, unfortunately, was not left there. Cultivated 1860. Zone 4 to 9.

ULMUS POSTSCRIPT

Considerable enthusiasm for elms and breeders, plantspeople, and nurseries continue to introduce new cultivars. Keith Warren, J. Frank Schmidt & Son, Inc., Boring, OR, planted a collection in a parking island using 'Frontier', 'Patriot', Accolade™, Triumph™, Danada Charm™, 'Emerald Sunshine', 'New Horizon', 'Princeton', 'Jefferson', and 'New Harmony'. I look forward to assessing the winner(s).

Dr. George Ware, Morton Arboretum, continues the elm evaluation work with 12 Chinese species including *U. gausсенii* (Anhui), *U. bergmanniana* (Bergman), *U. chenmoui* (Chemou), *U. castaneifolia* (Chestnut), *U. propinqua* var. *suberosa* (Corkbark), *U. davidiana* var. *mandshurica* (Father David), *U. glaucescens* var. *lasiocarpa* (Gansu), *U. harbinensis* (Harbin), *U. lamellosa* (Hebei), *U. prunifolia* (Plum-leaved), *U. taihangshanensis* (Taihang Mountain) and *U. microcarpa* (Tibetan). Dr. Ware is intrigued by the Anhui elm as it thrives in streamside habitats and thus may tolerate low oxygen levels.

I mentioned the *Ulmus parvifolia* 'Small Frye' that I discovered in Athens. If it pans out in the propagation and production phases, it would prove a great contributor because of superior foliage, bark and restrained habit. One could breed for these criteria and *never* succeed in a lifetime. Serendipity plays a notable role in new tree discoveries.

Vaccinium corymbosum L. — Highbush Blueberry

(vak-sin'i-um kôr-im-bô'sum)

FAMILY: Ericaceae

LEAVES: Alternate, simple, ovate to elliptic-lanceolate, 1 to 3 1/2" long, half as wide, acutish, cuneate, entire, dark green above, paler beneath, pubescent on midrib and veins; short petioled.

STEM: Slender, yellow-green to reddish in winter, granular; pith—solid, green; overall effect is quite handsome in winter.

SIZE: 6 to 12' in height with a spread of 8 to 12'.

HARDINESS: Zone 3 to 7(8).

HABIT: Upright, multi-stemmed shrub with spreading branches forming a rounded, dense, compact outline, especially under cultivation.

RATE: Slow.

TEXTURE: Medium in all seasons.

LEAF COLOR: Dark green, almost dark blue-green in summer changing to yellow, bronze, orange or red combinations in fall; excellent fall coloring shrub; late color, superb red, early December at Coker Arboretum, Chapel Hill.

FLOWERS: White, possibly tinged pink or pinkish, urn-shaped, 1/3" long, May, just before leaves completely unfold; borne in axillary racemes in great quantities.

FRUIT: Berry, green, reddish tinged, maturing blue-black, bloomy, rounded, 1/4 to 1/2" across depending on the cultivar, edible but require a complement of sugar; July through August.

CULTURE: Transplant balled-and-burlapped or from a container into moist, acid, organic, well-drained soils (pH 4.5 to 5.5); native to somewhat swampy soils but does extremely well under acid, sandy conditions; chlorosis is a significant problem and pH of the soils should be the first concern of anyone desiring to culture blueberries; actually they are very easy to grow if given the above conditions; mulch to reduce injury around roots and preserve moisture; prune after fruiting; full sun or partial shade.

DISEASES AND INSECTS: Actually the cultivated blueberries are subject to a number of insects and diseases; if the shrub is being grown for ornamental rather than commercial purposes no extensive control program is necessary and there are usually sufficient fruits for a few pies, jams, and the birds.

LANDSCAPE VALUE: Could blend well into the shrub border or small garden plot; two or three plants will provide many quarts of berries; it is wise to check with the local extension service or the state university to determine the best cultivars for a given area; Bonnie and I sequestered a few bushes here and there in the garden, always some fruits for birds, Cheerios and gobbling on-the-go; the species is everywhere I travel in the East—swamps, woods in the understory, mountain sides; almost ubiquitous from Maine to Florida; lifestyle plant offering health benefits including preventing/delaying cancers, slowing the aging process (memory and motor skills) and strengthening blood vessels; one cup of blueberries proves 15% of Vitamin C and 14% of daily dietary fiber.

CULTIVARS: Numerous selections and hybrids have been named and are preferable to the wild types. When selecting cultivars for your garden, write or call your county extension service to find out which are best for your area. Note that the cultivars also vary in shape, vigor and productivity as well as size, color, and taste of the fruit. Although single cultivars can be planted, more than one cultivar should be planted for best pollination. Counted about 42 patented cultivars on www.uspto.gov in March 2009.

'Berkeley'—Mid-season, vigorous, spreading, and productive. Light-blue fruits of good quality are quite large; berries store well and generally ripen one week after 'Blueray'.

'Blue Haven'—Medium size, light blue, excellent flavor; 4 to 5' high.

'Blue Ridge'—Low chill, early mid-season form, field tolerance to stem blight; medium to large fruit, excellent color, firmness, pleasant high acid flavor, see *HortScience* 25(12):1668–1670 (1990).

'Bluecrop'—Midseason; hardier and more drought resistant than most; upright shrubs are unusually productive to the point of overbearing; medium to large, light-blue fruit of good quality, fruit flesh is firm, resistant to cracking, and flavor is good; plants are vigorous, spreading and consistently productive; the ripening time is similar to 'Blueray'; 4 to 6' high; 'Blueray' and 'Bluecrop' appear to be a good combination for cross-pollination.

'Bluegold'—Medium to large size, firm, light blue fruits; compact, 4 to 5' high.

'Bluejay'—Early to mid season highbush with medium to large, light blue fruit; 5 to 7'; rapid grower.

'Blueray'—Midseason; very hardy, upright, exceptionally vigorous bush produces large, light-blue, highly flavored tart fruit; ripens 1 to 2 weeks after 'Bluetta', depending on vigor; 'Blueray' grows to heights of 4 to 6', and its diameter is similar; summer leaf color is a glossy, dark green, giving way to bright red in fall; its red stems stand out in the winter; a neat, compact grower.

'Bluetta'—Medium vigor, productive bush which ripens in June.

- 'Bounty'—Produces high yields of large, good quality fruit, recommended for fresh fruit production; tolerant to *Botryosphaeria dothidea*, resistant to *B. corticis*, see *HortScience* 24(1):161–162 (1989).
- 'Brigitta'—Large light blue fruits with good flavor, described as sweet yet slightly tart; Australian cultivar.
- 'Burlington'—Late; vigorous, upright, moderately productive shrub; small to medium, light-blue fruit of fair dessert quality.
- 'Cape Fear'—Low chill, mid-early ripening, precocious, large fruit, fine color, firmness, average quality, see *HortScience* 25(12):1668–1670 (1990).
- 'Chandler'—Large mid blue fruits with excellent flavor, long ripening season; dark green foliage; 5 to 6' high.
- 'Collins'—Ripens with 'Bluetta'; fruit is light blue, sweet, and has an excellent flavor.
- 'Coville'—Late; very vigorous, spreading bush with large, light-blue berries of good quality when fully ripe.
- 'Darrow'—Large light blue fruits, juicy robust flavor; 4 to 6'.
- 'Dixi'—Late; vigorous, spreading bush that is not very hardy; large, medium-blue berries are of excellent quality but subject to cracking.
- 'Duke'—Early; vigorous, productive, commercial cultivar; 4 to 5' by 4 to 5'; large, medium blue, crisp-flavored fruit.
- 'Earliblue'—Early; vigorous, upright bush with large, good quality, sweet berries.
- 'Elliot'—Medium-size, powder-blue, firm; slightly tart fruits; more upright, reaching 6' high and spreading as much as 4 to 5' in diameter; leaf color during summer is bluish green, turning to orange-red in fall.
- 'Hardyblue'—Medium size, light blue, firm, sweet fruits, very productive; 4 to 6', established cultivar in the Pacific Northwest.
- 'Herbert'—Late; vigorous, upright bush; medium-blue, sweet berries are among the largest and best quality; fruit is resistant to cracking and does not shatter; ripening time is late June.
- 'Jersey'—Late; an old favorite and perhaps the most widely grown; vigorous, upright, very productive bush; large, light-blue berries are acidic when picked early but sweet when fully ripe; 'Jersey' and 'Rubel' are the only cultivars to survive bad winter and late-spring frosts at Geneva, NY.
- 'Late Blue'—Large blue fruits maturing into September.
- 'Legacy'—Medium to large, light blue, robust flavored fruits; may hold leaves through winter; foliage turn bright orange in cold climates; 6' by 6'.
- 'Nelson'—Large light blue, firm, flavorful fruits, productive; selected from crosses of 'Bluecrop' and 'Berkeley'.
- 'Northland'—Can be used from the Canadian provinces into Zone 7; medium-size, mid blue, sweet fruits, highly productive; bright green, oval leaves that turn orange in the fall; height exceeds 4', and it spreads to a 5' diameter.
- 'November Glo'—Developed by the late Dr. Arthur Elliott in Michigan, it was named for retaining the fiery red foliage throughout November and December; plants reach heights of 4 or 5' and can be used as accent plants and hedges; foliage has good color on its graceful, lance-shaped leaves.
- 'Olympia'—Medium to large, mid blue, sweet fruits.
- 'Patriot'—Early, medium blue, sweet, large, about 25-cent size; upright grower; first witnessed at Wisley Garden and was amazed at the size of the fruits . . . gigantic; apparently *Phytophthora* resistant.
- 'Pemberton'—Late; unusually vigorous, erect bush that bears a year or two earlier than most; productive; but medium-blue berries are difficult to pick and subject to cracking in wet weather.
- 'Pink Champagne'—Dark pink fruits with good flavor; early to mid season; highbush; USDA-ARS introduction.
- 'Pink Lemonade'—Bright pink fruits, mild pleasant flavor; mid-late to late season ripening; USDA-ARS introduction.
- 'Rancocas'—Red stems, good foliage, heavy fruits.
- 'Reka' (PP 6,700)—Medium size, flavorful fruits; burgundy-red fall color; 4 to 6'; from New Zealand.
- 'Rubel'—Good flavored fruits in midseason and red fall foliage.
- 'Spartan'—Early (after 'Dixi'); large, light blue fruit; vigorous upright grower, 5 to 6'.
- 'Sunrise'—Early-maturing tetraploid; large fruit; larger plant stature, 5-year-old plants grow 5 1/4 to 6' high; resistant to red ringspot virus, see *HortScience* 26(3):317–318 (1991).
- 'Toro'—Early to midseason; good for commercial production; sky-blue fruits; 5 to 6'.
- 'Weymouth'—Early; erect bush of below average vigor with medium-size, dark-blue berries of poor dessert quality that fall off the plant.

SOUTHERN Highbush Varieties

These plants flower and ripen their berries before rabbiteye (*V. ashei*) blueberries.

- 'Avonblue'—Very early season, ripens one week after 'Sharpblue'; very prone to overbearing and pruning is necessary to balance the fruit load; young plants must be defruited to obtain good growth; blooms a week after 'Sharpblue'; 400 chilling hours (45°F or below) required to satisfy bud rest and allow flowers to open and develop normally.

'Flordablue'—Very early season; difficult to propagate and grow; ripens one week after 'Avonblue'; 300 chilling hours required.

'Sharpblue'—Very early season; self-fertile, therefore, it may be planted in solid blocks; does not grow as fast as rabbiteyes and the fruit must be stripped when the plants are young to obtain good growth; necessary to prune off excess flowers on older plants; it must be grown on well-drained soil to prevent root rot; subject to early blooming and bird damage; fruits have a wet scar when picked, but can be shipped with careful management; grows as far south as Homestead, FL; it is slow growing, maturing at a height of 4 to 5'; typical glossy green leaves that change to orange-red in fall; with its compact growth, large leaves and neat growing habit, it makes an altogether satisfactory landscape plant; 300 chilling hours required.

'Southland'—Moderately vigorous, dense, compact plant; light blue, medium to large fruits of good flavor.

PROPAGATION: Seed, some species germinate immediately, others germinate over a long period of time.

Seeds of *V. corymbosum* do not require pretreatment. Cuttings, especially softwood, collected in June root readily under mist in peat:perlite when treated with 1,000 ppm IBA; I have had good success this way; a rooting hormone may not be necessary but is always a good safeguard.

ADDITIONAL NOTES: There are about 150 species (have seen 450 species listed) of *Vaccinium* and it is quite difficult to separate many of the types without a road map. Many make great garden shrubs because of fruit and fall color. In general they prefer an acid soil and if provided this reward one for many years. I remember a retired professor in Urbana, IL who was determined to grow *V. corymbosum* at all costs in the calcareous, high pH soil of the area. He went so far as to use HCl (hydrochloric acid) to acidify the soil in his garden and still had chlorotic plants. The best way to handle the problem under conditions like his is the use of raised beds and a medium like pine-bark, peat moss or some other acid organic. On a magnificent October day I scouted a Maine bog with Professor Bill Mitchell, formerly of the University of Maine, and saw *V. corymbosum* in fluorescent fall color growing in what appeared to be the wettest and most acid of soils.

In the fall of 1997, the blueberries at the Horticulture Farm were as vibrant red as I remember during my 30 autumns in the South. In early January 1998, Bonnie and I hiked the White Cedar Swamp on Cape Cod and in the wet peat bog soils, primarily on hummocks, grew *V. corymbosum*.

NATIVE HABITAT: Maine to Minnesota, south to Florida and Louisiana. Introduced 1765.

RELATED SPECIES:

***Vaccinium angustifolium* Ait. — Lowbush Blueberry**
(vak-sin'i-um an-gus-ti-fō'li-um)

LEAVES: Alternate, simple, lanceolate, 1/3 to 3/4" long, acute at ends, serrulate with bristle-pointed teeth, lustrous dark green above essentially glabrous on both surfaces; var. *laevifolium* House has larger leaves about 3/4 to 1 1/2" long and represents more southerly distributed members.

Vaccinium angustifolium, Lowbush Blueberry, is a low, straggly, open-growing shrub reaching 6" to 2' in height and spreading 2' and greater. The foliage is lustrous dark to blue-green in summer changing to bronze, scarlet and crimson in fall. The 5-lobed flowers are white, tinged pink to reddish, 1/4" long, April–May. Flowered May 28, 2005 along Route 15 on the road to Sedgewick and Deer Isle, Maine. The fruit is a bluish black, bloomy, very sweet berry, 1/4 to 1/2" across. Does extremely well in dry, acid, poor soils and is the main fruit crop in the state of Maine. Amazing plant that grows in the most sandy, rocky, impoverished soils imaginable. Wild blueberries are grown on 60,000 acres in Maine with only half this acreage available for harvesting each year. Most of the crop is frozen or canned with <1% sold fresh. Our annual late summer pilgrimage to Deer Isle, ME allows us to travel the route (15) not taken from US1. It snakes, curls, dips and dives heading toward the Atlantic when on Caterpillar Hill appears the most spectacular sight: Lowbush Blueberry fields, views of the ocean and islands. By late summer, the blueberries are initiating reddish foliage coloration, with residual glaucous blue berries remaining. We stop, photograph, sample, muse and appreciate. My vacation thoughts turn to blueberry cream pie, blueberry jelly, blueberry muffins . . . life on a late August day in Maine is wonderful. Interestingly, few, if any, commercial cultivars have been selected. The Lowbush Blueberry is a managed wild crop. The keys are weed management, burning, minimal to no fertility and Mother Nature. The value of the crop approximated \$40 million per year in the 1990's. For additional information write UMaine, Orono. University of Maine introduced six cultivars for ornamental rather than fruit value. All are prostrate, 5 to 7" high, 'Burgundy', 'Claret', and 'Jonesboro' are notable for deep red autumn coloration of leaves and stems while 'Pretty Yellow', 'Spring', and 'Verde' have green to greenish yellow leaves in autumn. 'Cumberland' and 'Fundy' are sweet, large-fruited, fresh market cultivars, released by Agricultural Canada, see *Canad. J. Plant Sci.* 68(2):553–555 (1988). 'Ruby Carpet' (PPAF) has deep green summer foliage that turns fluorescent red in fall; low growing, 4 to 6" high; selected for adaptability to drier soils. 'Brunswick' has sky blue, pea-sized fruit; glossy dark green leaves, red fall color; 1 1/2' to 2' high; from Nova Scotia. Newfoundland to Saskatchewan, south to the mountains of New Hampshire and New York. Introduced 1772. Zone (2)3 to 5(6).

***Vaccinium arboreum* Marsh.** — Farkleberry, Sparkleberry
(vak-sin'i-um är-bō'rē-um)

LEAVES: Alternate, simple, obovate to oblong, evergreen, semi-evergreen to deciduous depending on location, 1/2 to 2" long, about half as wide, acute or obtuse, entire or obscurely denticulate, leathery, lustrous dark green and glabrous above, slightly pubescent beneath or downy.

Vaccinium arboreum, Farkleberry or Sparkleberry, is abundant in the University's Botanical Garden as an understory plant in rather dry woods. It ranges from a spreading shrub to a 15 to 20' small tree. Co-national champions are 18' by 31' in Houston, TX and 28' by 41' in Choctaw, AL. The 1/2 to 2" long, leathery dark green leaves turn rich red to crimson in fall. The 1/4" long, white, reflexed, 5-lobed flowers appear with the emerging fresh green spring leaves and are followed by 1/4" diameter, shiny, black, inedible, persistent fruits with 8 to 10 seeds. The bark exfoliates and is composed of grays, rich browns, oranges and reddish brown. This is one of the most handsome native understory plants in deciduous woods. Heat and drought tolerances are legendary. Difficult (perhaps impossible) to root from cuttings and seeds represent the greatest hope. A pink-flowered form is in the process of being propagated and introduced into cultivation by Ted Stephens, Nurseries Caroliniana. Virginia to North Carolina to Florida, southern Illinois and Texas. Introduced 1765. Zone 7 to 9.

***Vaccinium ashei* Reade**, (vak-sin'i-um ash'ē-ī), Rabbiteye

Blueberry, is best described as the southern equivalent of *V. corymbosum* in modern taxonomy. GRIN lists *V. virgatum* Ait. as the correct species. In general, Rabbiteye is similar to Highbush but is better adapted to culture in the southern states. Habit is upright with landscape size approximating 8 to 10' high. Many selections have been made for superior fruiting characteristics. The foliage of some selections is a glaucous blue-green and genuinely attractive. The plants color well in the fall and are enthusiastically recommended by this author for the home landscape. Magnificent red fall

color, early December, in the planting at the Horticulture Farm, Athens. Because the rabbiteye blueberry requires cross-pollination for maximum fruit set, plant 3 or more cultivars with a minimum of 2 cultivars. Chill hours refer to the number of hours at 45°F or below necessary to satisfy bud rest and allow flowers to open and develop normally. Several good extension publications exist and those desirous of additional information should write the Horticulture Department, University of Georgia. The University has a long-term tradition in blueberry breeding, now directed by Dr. Scott NeSmith, Griffin Experiment Station. He has many exciting potential introductions in the pipeline. To date, his releases include: 'Alapaha' (PP 16,266), 'Ochlockonee' (PP 17,300), 'Vernon' (PP 18,291), 'Camellia' (PP 18,151), 'Palmetto' (PP 16,756), and 'Rebel' (PP 18,138) forms of southern highbush blueberry. Zone 7 to 9.

Cultivars include:

- 'Alapaha' (PP 16,266)—Late flowering, early ripening, reduction in frost damage, increased productivity of high-quality fruit.
- 'Austin'—Early ripening, medium to large, high quality fruits for mechanical harvesting, 450 to 500 chill hours; named to recognize the contributions to blueberry industry of Max Austin, retired professor, Horticulture, University of Georgia, see *HortScience* 32(7):1295–1296 (1997).
- 'Baldwin'—Late season, vigorous and upright with fruit of medium size; the ripening season may extend into August and September and is an excellent choice for you-pick operations where late season fruit is desired; not recommended for mechanical, fresh market harvest; 450 to 500 chill hours.
- 'Beckyblue'—Early season; a University of Florida release for the fresh fruit trade; blooms early, 300 chill hours.
- 'Biloxi'—Medium size, light blue, firm, strong-flavored fruit; vigorous grower; about 400 chill hours; 1998 USDA release.
- 'Bladen'—Upright vigorous grower, early ripening, medium-sized fruit, good flavor and productivity; easy propagation via softwood and hardwood cuttings; hybrid of *V. darrowi* Camp, *V. corymbosum*, *V. tenellum* Ait., and *V. ashei*, see *HortScience* 30(1):150–151 (1995).
- 'Bluebelle'—Mid-season; plants are moderately vigorous with upright growth; berries are large, round, light blue, and have excellent flavor, fruit ripening beginning in midseason and extends over a relatively long period; under favorable conditions the berries size well throughout the season and production is high, thus being an excellent pick-your-own variety; berries tend to tear when harvested, therefore, this variety is not recommended for shipping; 450 to 500 chill hours.
- 'Bonita'—Early season; a fresh fruit shipping variety from Florida; the shrubs are vigorous and ripen about three days after 'Climax'; blooms early so it is best planted by 'Woodard' or 'Beckyblue'; about 300 chill hours.

- 'Brightwell'—Early season; introduced by the University of Georgia Coastal Plain Experiment Station in 1982; plants are vigorous and upright; berries are medium in size, have small, dry stem scars and good flavor; 'Brightwell' ripens over a relatively short period beginning after 'Climax' and about the same season as 'Woodard'; suitable for mechanical harvest; 350 to 400 chill hours.
- 'Briteblue'—Mid-season; moderately vigorous and grows upright and open; berries are light blue, large, and very firm with good flavor when fully ripe, season of ripening is generally before 'Tifblue'; berries are easily hand picked because they grow in clusters; mature berries have a long retention on the plant and are an excellent choice for pick-your-own operations; 400 to 650 chill hours.
- 'Camellia' (PP 18,151)—Excellent fruit attributes, especially size and color; relatively late flowering for an early to mid season variety; excellent vigor under field and high density conditions.
- 'Centurian'—Late season, medium to large, dark blue fruits with crisp, aromatic flavor; lustrous, leathery, dark green leaves.
- 'Climax'—Early season; plants grow upright and open; berries are medium in size and medium dark blue in color, have a small scar and good flavor; fruit ripening begins 3 to 5 days before 'Woodard', concentrated ripening with few shriveled or overripe fruit; excellent for mechanical harvesting; 450 to 550 chill hours.
- 'Cooper'—Upright grower; selected for fruit production in early June for the southeastern coastal plains; hybrid with 72% *V. corymbosum*, 25% *V. darrowi*, and 3% *V. angustifolium*, see *HortScience* 29(8):923–924 (1994).
- 'Delite'—Late season; moderately vigorous producing an upright plant; berries are light blue, sometimes being a reddish blue when ripe, large and firm, and have excellent flavor, not sharply acid before fully ripe; season is slightly later than 'Tifblue'; 500 chill hours.
- 'Georgiagem'—Moderately vigorous, semi-erect; produces moderate yields of medium-sized fruits of good flavor, color and firmness; ripens 15 days earlier than 'Climax'; requires at least 350 hours of chilling below 45°F, see *HortScience* 22(4):682–683 (1987).
- 'Gulfcoast'—Similar to 'Cooper' but flowers and fruits earlier (mid-May); same pedigree as 'Cooper', see *HortScience* 29(8):923–924 (1994).
- 'Jubilee'—Sweet, sky-blue fruits produced in large clusters and ripen over two weeks; brilliant red fall foliage; 500 chilling hours; 5 to 6' high and wide.
- 'Misty'—Low chill, 100 to 300 hours, selection for early season production and upright, vigorous growth habit to 6' or more; see *HortScience* 32(7):1297–1298 (1997); USDA release.
- 'Ochlockonee' (PP 17,300)—Late flowering, high and consistent productivity, large berry size, moderate chill requirement, late ripening, high quality fruit.
- 'O'Neal'—Vigorous, semi-upright, early-flowering, self-fertile, low chilling (~400 hours) requirement; early-ripening, large fruits, good firmness and flavor; grows 6' high; see *HortScience* 25(6):711–712 (1990); developed at NC State University.
- 'Palmetto' (PP 16,756)—Early ripening, favorable commercial fruit attributes, concentrated ripening, good yield, excellent vigor.
- 'Powderblue'—Mid to late season; height averaging 6 to 10', spreads to 5 or 6' in diameter and does not sucker at the base; leathery oval leaves are bluish, coloring from bright yellow to orange in fall; stem color after leaf drop is green to yellow; similar enough to 'Tifblue' in appearance, quality, season and mechanical harvesting characteristics that the two can be harvested together and used as pollinators for each other.
- 'Premier'—Early season; a release from North Carolina State University; the shrubs are vigorous and productive, but the canes may be too limber to support the fruit load; similar in growth habit to 'Powderblue' except that its lanceolate leaves are a deeper green that turn to orange-red in the fall; stem color varies from red to burgundy; about 550 chill hours.
- 'Rebel' (PP 18,138)—Early ripening, high yield, excellent fruit attributes especially size and color, high plant vigor.
- 'Reveille'—Medium size, light blue, crisp flavored fruit; hot pink flowers; 5 to 6' high; 500 to 600 chill hours; NC State release in 1987.
- Rosa's Blush™—Metallic rose-pink new growth; *V. darrowi*.
- 'Southmoon' (PP 9,834)—Fruits have good flavor; 500 chill hours; reported to do well in lighter, sandy soils with generous added organic matter; 5 to 6'.
- 'Sunshine Blue'—Dense, rounded shrub, 3 to 4' high; red buds open to pink flowers; medium size, dark blue fruits in mid-season; self-fertile; from Ken Muir, *The Garden* November 2005.
- 'Tifblue'—Mid to late season; plants make vigorous, upright growth; this has been the best commercial variety from the standpoint of appearance, productivity, and shipping qualities, however, most years the fruits ripen too late to receive high fresh market prices; the large, light blue berries are very firm and are highly flavored; berries of this variety, like 'Woodard,' are very tart until fully ripe, berries remain on the plant several days after fully ripe; 550 to 650 chill hours.

'Vernon' (PP 18,291)—Late flowering, early ripening, high and consistent yield, large fruit size, excellent plant vigor.

'Woodard'—Early season; plants are the shortest and most spreading of the rabbiteye varieties, plant sprouts over an area of 3 to 4' in 6 to 10 years and do not grow as tall as 'Tifblue', so they may be hand picked more easily; berries are light blue and are large early in the season, the quality of the berries is excellent when they are fully ripe but are very tart until ripe; 'Woodard' ripens 7 to 10 days before 'Tifblue'; a poor choice for fresh market sales, because it is too soft; 350 to 400 chill hours.

OTHER VACCINIUM (BLUEBERRY) HYBRIDS AND CULTIVARS:

'Ornablu'—According to a West Virginia University publication, it is a hybrid between *V. corymbosum* and *V. pallidum* collected from the wild in Alabama; during its 12th season in the field, it was about 3' tall and 5 1/2' in diameter, making it suitable for specimen planting; 'Ornablu' manifests all the attributes of the blueberry family in a pronounced manner; declared unfit for competition with commercial fruit varieties, however, someone fell in love with its beauty, and it was saved from being grubbed out.

'Top Hat' ('Tophat')—A release from Michigan State University developed at the South Haven Experimental Station; named for its neat, very dense growth, which is reminiscent of that of *Viburnum opulus* 'Nanum'; result of crosses between *V. corymbosum* and *V. angustifolium*; matures at about 18"; small, glossy leaves, white bell-shaped flowers, delicious berries and fiery, red fall color; besides being used in landscapes where a low plant is desired, it can also serve as a container plant for the patio and as an excellent bonsai subject.

The University of Minnesota and others introduced the half-high series, hybrids between *V. corymbosum* × *V. angustifolium* that survive -40°F, these cultivars may grow slightly taller in warmer areas. See *HortScience* 21(5):1240-1242 (1986) for full descriptions of the Minnesota half-high North series.

'Chippewa'—Half-high, with sweet, low acid, light blue berries; hardy; listed as self-fruitful; 4' by 4'; introduced in 1996.

'Friendship'—Similar in height and growth habit to 'Northcountry'; fruits are mild, subacid, sweet, sky blue with waxy bloom; see *HortScience* 25(12):1667-1668 (1990).

'Northblue'—Half-high, taller than 'Northsky', growing to 25" (30"); large fruit, high yield, produces more fruit than 'Northsky'; hardy; introduced in 1981.

'Northcountry'—Half-high, medium low-growing, grows 24" high, 30 to 40" wide; sweet, mild, sky blue fruits, excellent flavor, similar to 'Northblue'; plant with other cultivars to improve fruit set, introduced in 1986.

'Northsky'—Light blue fruits with good flavor; about 10 to 18" tall, 2 to 3' wide, dense, with glossy, dark green summer foliage that turns dark red in the fall; introduced 1981.

'Polaris'—Half-high, with highly aromatic, firm, light blue berries, bright orange-red fall foliage; 4' by 4'; introduced 1996; needs a pollinator.

'St. Cloud'—Half-high, moderate growth habit, good yield; introduced 1990.

Vaccinium crassifolium Andrews, (vak-sin'i-um kras-i-fō'li-um), Creeping Blueberry, is scarcely a household name in American gardening circles but might deserve consideration for ground cover use. The lustrous dark green, finely serrate, 1/3 to 3/4" long, 1/8 to 3/8" wide, oval leaves are spaced about 1/4" apart along the stem. The reddish petiole is only about 1/16" long. The rosy red, 1/4" diameter flowers occur in short lateral and terminal racemes in May. The evergreen nature makes it a good candidate for ground cover use in the southeastern United States. If provided a sandy, well-drained situation it might prove adaptable. Will probably grow 6" (2' is listed) high and has the potential to spread many times its height. 'Wells Delight' offers lustrous elliptic dark green leaves and outstanding disease tolerance; 'Bloodstone' is a *V. crassifolium* subsp. *sempervirens* form with reddish new growth that matures to lustrous dark green, will grow 6 to 8" high and makes a rather pretty ground cover. In winter, the maturing foliage assumes an attractive reddish cast and the stems become distinctive dark red. Susceptible to *Phytophthora* and stem anthracnose. My observations indicate that these cultivars require a well-drained soil. 'Bloodstone' perished after several years on the Georgia campus. Simply never grew off and prospered. See *HortScience* 20:1138-1140 (1985) for specifics on both cultivars. North Carolina to Georgia. Introduced 1787. Zone 7 to 8.

Vaccinium elliotii Chapm.
(vak-sin'i-um el-i-ot'ē-i)

LEAVES: Alternate, simple, tardily deciduous, elliptic-ovate, 1/2 to 1 1/4" long, one-third to one-half as wide, acute to acuminate, finely serrate, rich green, shining, thin, glabrous or sparsely pubescent, particularly so on the lower surface; petiole—short.

STEM: Slender, green, almost grass green, turning reddish in autumn.

Vaccinium elliotii, is a 6 to 12' high, slender branched shrub that often occurs as an understory plant in deciduous woods. Habit is upright arching with long, slender, supple, green shoots. The small, handsome, green leaves turn rich red and reddish purple in fall. Fall color persists into December and, in the deciduous woods in the Southeast, where most leaves are now mulch, this species is quite showy. As mass planting, naturalized-type situation, would prove potent. The white to pink, 1/4" long, narrowly urceolate flowers often open before the leaves. Flowers occur in 2- to 6-flowered fascicles from the buds of the previous season's wood. The 1/5 to 2/5" long, black berries ripen in summer. Grows in a wide variety of habitats from wet to well-drained, stream banks, wet thickets, bottomland woodlands. This is a wonderful understory plant that along a woodland edge would be superb. My observations of native populations indicate phenomenal resiliency. Species needs an advocate. Southeastern Virginia to north Florida, westward to east Texas and Arkansas. Zone 6 to 9.

***Vaccinium stamineum* L. — Deerberry**
(vak-sin'i-um stam-in'ē-um)

LEAVES: Alternate, simple, elliptic, ovate, oblong, obovate, or sub-orbicular, 3/4 to 3" long, 1/3 to 1 1/4" wide, acute to short acuminate, cuneate to rounded to subcordate at base, entire, occasionally serrate, rich green to glaucous blue-green, pubescent to varying degrees above (less) and below (more); petiole—short.

Vaccinium stamineum, Deerberry, is a variable shrub from 3 to 15', usually inhabiting well-drained soils, often sandy in nature. Foliage varies from green to glaucous blue-green. The white flowers appear with the leaves in April–May (April, Chapel Hill, NC) with the pistil-stamen complex about twice as long as the petals. The fruits range from 1/5 to 3/5" diameter, are ovoid, globose to slightly pear-shaped and color from whitish to dark purple, bloomy or not, largely inedible. This is a terrifically variable species worthy of use for naturalizing. I have observed 2 to 3' high shrubs in sandy woods and 10' high shrubs in improved soil. Have seen blue foliage types that rival a Blue Colorado Spruce. Massachusetts to Minnesota, south to Florida and Louisiana. Doubtfully well-adapted to heavy, wet soils. Introduced 1772. Zone 5 to 9.

***Vaccinium macrocarpon* Ait.— American Cranberry, Large Cranberry**
(vak-sin'i-um mak-rō-kär'pon)

FAMILY: Ericaceae

LEAVES: Alternate, simple, evergreen, 1/4 to 3/4" long, 1/8 to 1/3" wide, elliptic-oblong, flat or slightly revolute, slightly whitened beneath, lustrous dark green in summer assuming reddish purplish hues in fall and winter; petiole—short.

BUDS: Small or minute, solitary, sessile, with 2 apparently valvate scales or the larger with some half-dozen scales.

STEM: Slender, very obscurely 3- or 5-sided or distinctly angled; pith small, nearly round, continuous; leaf scars small or minute, half-rounded or crescent-shaped, somewhat elevated; 1 bundle trace.

SIZE: 2 to 6" in height, spread is indefinite.

HARDINESS: Zone 2 to 6.

HABIT: Low, dense, small-leaved evergreen ground cover.

RATE: Slow to medium; I have grown plants in containers with excellent success.

TEXTURE: Beautifully fine in all seasons.

LEAF COLOR: Glossy medium to dark green in summer; new growth is often bronzy; during cold weather the foliage takes on reddish bronze to reddish purple hues.

FLOWERS: Perfect, pinkish, 1/3" across, corolla deeply 4-cleft with revolute linear-oblong lobes, borne solitary, axillary, nodding, jointed with pedicel; May–June; not showy but interesting from a morphological viewpoint.

FRUIT: Berry, red, globose, 1/2 to 3/4" across, acid, ripening in September or October.

CULTURE: Transplant as a container-grown plant into a moist, high organic matter soil; in the wild is found growing in moist sphagnum bogs; full sun, possibly light shade; most important to keep the roots cool and moist.

DISEASES AND INSECTS: Many associated with commercial production but nothing of consequence for the homeowner to worry about; review of the literature indicated more problems than I realized with commercial production; not as easy as Ocean Spray makes it look.

LANDSCAPE VALUE: A novelty evergreen ground cover which is quite handsome. I have had good success with container-grown plants which were transplanted into a 1/2 soil:1/2 sphagnum peat mixture.

CULTIVARS:

'Ben Lear'—Early-ripening, deep red fruits; from a native Wisconsin population.

'Hamilton'—A compact form, non-vining, slow-growing, pink flowers.

Lo-Hugger™ ('Lohzam')—A 4 to 6" high ground cover; shiny dark green leaves turn red-bronze in winter, reads like the species; in fact, as I perused the description in Lake Country Nursery's 2007–2008 catalog I was looking for unique traits to justify the introduction.

'Select'—Shiny dark green leaves, red-bronze in winter; large red fruits.

'Stevens'—A commercial variety that produces abundant fruit.

PROPAGATION: Seeds require 3 months cold stratification for best germination. Cuttings are easy to root. Softwood cuttings treated with 1,000 ppm IBA, placed in peat:perlite under mist rooted 80% in 6 weeks.

ADDITIONAL NOTES: The American Cranberry is the source of the cranberries which we relish during the holidays and for that matter the rest of the year. My children consumed vats of the tangy, tart juice. Like *V. angustifolium* and *V. corymbosum*, true American fruits. Massachusetts and Wisconsin are the leading states in cranberry production and a trip to Cape Cod at harvesting time (or for that matter any time) is well worth the effort. In mid-January, Bonnie and I spent a delightful sunny day on the Cape touring and hiking. In Sandwich, off Route 6A, a flat-surfaced reddish haze, acres in scope, caught our attention. Indeed, a cranberry bog, on such a fine sunny day, was the center of the plant universe. Very interesting crop as far as cultural and nutritional practices are concerned and anyone interested should consult a text on modern fruit production.

NATIVE HABITAT: Newfoundland to Saskatchewan, south to North Carolina, Michigan and Minnesota. Introduced 1760.

RELATED SPECIES:

***Vaccinium oxycoccos* L.**, (vak-sin'i-um ok-si-kōk'ōs), Small Cranberry, European Cranberry, has 1/6 to 1/3" long, dark green, evergreen, strongly revolute, ovate to oblong-ovate, tinged blue beneath leaves on a creeping framework of filiform stems. Flowers and fruits smaller than those of *V. macrocarpon*. The red, 1/4 to 1/3" diameter fruits are rounded to pear-shaped and may persist on plants through winter. Found in northern Europe, Asia and America. Cultivated 1789. Zone 2 to 5.

***Vaccinium vitis-idaea* L.** — Cowberry, Foxberry
(vak-sin'i-um vī'tis ī-dē'a)

LEAVES: Alternate, simple, oval to obovate, 3/8 to 1" long, half as wide, often notched at apex, leathery, lustrous dark green, lower surface sprinkled with black dots; short-stalked.

Vaccinium vitis-idaea, Cowberry, may grow to 10" (4 to 12"). The evergreen foliage is lustrous dark green above and paler dotted beneath; turns metallic mahogany in winter. The flowers are white or pinkish, campanulate, 4-lobed, 1/4" long; May through June; borne in short sub-terminal nodding racemes. The fruit is a dark red, 1/4 to 3/8" diameter berry with an acid, bitter taste; ripens in August. Culturally it performs best on moist, peaty soil and in full sun. The variety (subspecies) *minus* (Lodd. et al.) Hulten, Mountain Cranberry, Lingonberry, is lower growing (4" rarely 8") and hardier (Zone 2) than the species. The variety ranges from Labrador to Massachusetts to Alaska and British Columbia (Cultivated 1825) while the species is native to Europe and northern Asia. Cultivated 1789. Zone 5. I have seen the variety *minus* in Maine and have come to cherish and appreciate it for the refined, dainty habit and the excellent evergreen foliage. Variety *majus* Lodd. is listed with larger fruits and leaves 1 to 1 1/2" long. Many cultivars have been selected in Europe where the plant is more popularly known as Lingonberry and assumes fruit crop status. Famous for making tart jelly, jams, juices and sauces. Please send me a jar if you have multiples. Many cultivars of var. *majus* have been selected for fruiting qualities. 'Erntdank' produces heavy crops of medium-sized berries; 'Erntkrone' has large, dark red fruits; 'Koralle', one of the most widely grown forms, produces two harvests of bright red, pea-sized fruits per year on a 12" by 12" framework; and 'Masovia' bears abundant fruits. University of Wisconsin released 'Splendor' and 'Regal' lingonberries for use in breeding or commercial production; see *Fruit Varieties J.* 48(3):182–184 (1994). Tissue culture propagation of cultivars is widely used; see *Fruit Varieties J.* 48(1):7–14 (1994).

Viburnum L. — Viburnum

FAMILY: Adoxaceae (also placed in Caprifoliaceae and Viburnaceae)

A garden without a viburnum is akin to life without music and art. I have a special fondness for this great group of plants that numbers about 150 species and contains numerous cultivars. They range in size from 2 to 3' to 30'(60'), in odor from the sweetest perfume to the stenchiest stink, in flower from white to pink (rose), and in fruit color from yellow, orange, pink, red, blue, and black. The late Dr. Donald Egolf, U.S. National Arboretum, introduced 18 superior types, all of which are presented here. For many years viburnums were slighted in the mid south region but I now see *Viburnum plicatum*, *V. p. f. tomentosum*, *V. macrocephalum*, *V. xpragense*, *V. xburkwoodii* and many of Dr. Egolf's excellent selections becoming almost commonplace. For additional information see Wyman, Krüssmann, Bean, and Dirr, *American Nurseryman* 150(9), (1979) and *Plants and Garden Handbook* 37(1):32–35 (1981). Also, Kathleen Fisher's article on Donald Egolf's Viburnums, *Amer. Horticulturist* 68(10):30–35 (1989) is required reading.

My Ohio State education had much to do with instilling this great love of viburnums. In the woody plants course we were required to learn about 22 different viburnums. The initial force-feeding energized my system and to this day I become excited when a flowering or fruiting specimen of a worthy viburnum species confronts my everyday life. In Rowallane, Northern Ireland, on a fine June day, I witnessed the cultivar 'Rowallane' in glorious flower. Having only read about this clone of *V. plicatum* f. *tomentosum*, it was exciting to experience the genuine article. Likewise, on the Blue Ridge Parkway in North Carolina, where in July *Viburnum cassinoides* grew on the mountainsides in profusion; that same species in late August to early September with glaucous pinkish to rose, maturing to blue-black and purple-black fruits.

Met a viburnum companion, Gary Ladman, Classic Viburnums, 1385 Q Rd, Upland, Nebraska at the Western in Kansas City. Gary and Susan visited Bonnie and me in spring 2007. Rain, lightning, thunder and we are on the trail of *V. nudum* in the wild. Amazing we are alive but then considering the cause. . . .

In the previous edition, I mentioned the possibility of a *Viburnum* book. The book was published in late summer 2007 by Timber Press and is more comprehensive with over 420 color photographs. Lloyd Kenyon's book on Viburnums, 2001, *Viburnum* is also an excellent reference. In the 6th edition I have primarily updated and expanded the cultivar treatments based on the treatment in the *Viburnum* book.

Viburnum acerifolium L. — Mapleleaf Viburnum, Dogmackie

(vī-bēr'num ā-sēr-i-fō'li-um)

LEAVES: Opposite, simple, suborbicular to ovate, 3-lobed, sometimes slightly so, 2 to 4"(5") long, about as wide, the lobes acute to acuminate, rounded to cordate at base, coarsely dentate, slightly pubescent above and dark green, more densely so and with black dots beneath; petiole—1/2 to 1" long, pubescent.

BUDS: Remind of *V. dentatum*.

STEM: Pubescent in youth, brown, glabrous with maturity.

Viburnum acerifolium is a low, sparsely branched shrub growing 4 to 6' tall and 4' wide. Clonal suckering thickets may extend forever.

The foliage is bright to dark green in summer changing to reddish purple in fall. The flowers are yellowish white, all fertile, early June (early May, Athens), borne in 1 to 3" diameter, long-stalked, flat-topped, terminal cymes. Have observed pink budded seedlings in nature but the color is lost as the flowers open. The fruit is a black, ellipsoidal, 1/3" long drupe which ripens in September and often persists into winter. An extremely shade tolerant species reserved for naturalizing. The habit could best be described as suckering for it develops rather large, loose, open colonies in the wild. Is adapted to shade and rather dry soils as it occurs in the understory of the forest in southern locales. It is an excellent plant for use in heavily shaded situations and I find the range of fall colors (creamy pink, rose, red to grape-juice purple) intriguing. Roots well from June–July cuttings. New Brunswick to Minnesota, south to North Carolina and Georgia. Introduced 1736. Zone 4 to 8.

*Viburnum xburkwoodii* Burkw. & Skipw. — Burkwood Viburnum

(vī-bēr'num bērk-wood'ē-ī)

LEAVES: Opposite, simple, oblong, ovate to elliptic, 1 1/2 to 4" long, 3/4 to 1 3/4" wide, acute or obtuse, rounded or heart-shaped, indistinctly toothed, lustrous dark green above, a bit rough to the touch, much lighter

(gray-green) beneath and tomentose, veins-often rusty brown in color; petiole—1/4 to 1/2" long, scurfy-pubescent.

BUDS: Vegetative-foliose, naked, tomentose.

FLOWER BUDS: Clustered (cymose), 1/2" across, grayish pubescent, remind of small cauliflowers.

STEM: Light tan in color, tomentose.

SIZE: 8 to 10' with spread about 2/3's height; occasionally rounded to broad-rounded; 15' high plants at UGA Botanical Garden.

HARDINESS: Zone (4)5 to 8; has been injured at Minnesota Landscape Arboretum but is about the hardiest of the semi-snowball fragrant types; also injured in Orono, ME; fine at Morton Arboretum, Lisle, IL; performs well in Zone 7.

HABIT: Upright, multi-stemmed, often tangled mass of fine stems yielding a somewhat straggly appearance; never as dense as *V. ×juddii* and *V. carlesii* as the young growth extensions are elongated and seldom branched.

RATE: Slow to medium.

TEXTURE: Medium in foliage, medium in winter.

LEAF COLOR: Lustrous dark green above; light gray-brown beneath; holds green color late, tends toward a semi-evergreen character especially in southern states (Zone (7)8); fall color may be a sporadic wine-red.

FLOWERS: Pink in bud to white in flower, spicy, aromatic, almost *Daphne odora* fragrance, April, effective for 7 to 10 days, hemispherical, 5-rayed cyme approximately 2 to 3"(3 1/2") across, each flower 1/3 to 1/2" wide, with 5 spreading, rounded lobes, anthers pale yellow, often opens in late March in Athens (March 22, 2003), full flower April 9, 1993 and March 29, 1994.

FRUIT: Red changing to black, 1/3" diameter, ellipsoidal-flattened drupe, July–August, usually sparsely produced and of insignificant ornamental importance; have seen respectable fruit when other plants of a similar nature (taxonomic affinity) were in close proximity thus facilitating good cross pollination.

CULTURE: Most viburnums require a slightly moist, well-drained soil, are pH adaptable but prefer a slightly acid situation; probably should be moved balled-and-burlapped or as a container specimen, small plants can be handled bare root; avoid sulfur sprays as many viburnums are defoliated by them; a very serviceable group of plants of easy culture provided the soil is well-drained; nematodes in the south can be problematic; full sun to moderate shade.

DISEASES AND INSECTS: Bacterial leaf spot, crown gall, shoot blight, leaf spots, powdery mildew, rusts, downy leaf spot, spot anthracnose, spray burn (caused by sulfur sprays), viburnum aphid, asiatic garden beetle, citrus flatid planthopper, tarnished plant bug, thrips, potato flea beetle, dogwood twig borer, and seven scale species; although the list is impressive the viburnums are relatively free of major problems.

LANDSCAPE VALUE: Excellent choice for the shrub border, works well with broadleaf evergreens, fragrance permeates the entire garden; thrives even in a polluted environment; the more I travel the more convinced I am that this is an excellent garden plant; it is often considered a second class citizen among fragrant viburnums but its heat and cold tolerance are notable assets; it is definitely one of the best viburnums in the Midwest and South; some pruning is necessary to keep it looking good; in the Dirr Georgia garden and has followed me through the horticultural years; asks little, gives much; still delight picking an emerging inflorescence and inhaling the fragrance.

CULTIVARS:

American Spice™ ('Duvone', PP 17,751)—New introduction by Bailey Nurseries, St. Paul, Minnesota; relatively compact form, the original selection was 4' tall by 4 1/4' wide in 14 years. Foliage becomes lustrous medium to dark green in early summer, and leaves persist late into fall, eventually developing shades of deep red and purple with yellow and orange overtones. Leaves are 2 to 3 1/2" long, 1 1/4 to 2 3/4" wide, petiole 1/6 to 1/3" long. Flowers are reddish in bud and pure white when open, with a spicy fragrance. Inflorescences 1 1/2 to 2" wide. Fruits are 1/3 to 1/2" long, oblong-ellipsoidal drupes, red to black at maturity. Plant was discovered in a block of 'Sarcoxie' at Duvall Nursery, South Lyon, Michigan. Differs from 'Sarcoxie' in its compactness, earlier developing flowers and foliage (two to three days), and increased fragrance. Survived ten consecutive days of -20°F without snow cover in winter of 1993–94. Testing in Georgia and foliage is excellent. Has not flowered so 2010 will tell a tale.

'Anne Russell'—Resulted from a backcross between *V. carlesii* with *V. ×burkwoodii* made in 1951, was selected and named after his wife by John Russell at L. R. Russell Ltd., Richmond Nurseries, Windlesham, England. The habit is more rounded and densely twiggy than typical *V. ×burkwoodii*. The pink-budded, fragrant, 3" wide flowers occur in abundance. I have observed plants with red flower buds in England. At PMA Plant Specialties, Somerset, the red buds were as prominent as Christmas ornaments on a compact specimen. Leaves are primarily deciduous, owing to 75 percent *V. carlesii*, more rounded and more akin to *V. carlesii*, and not as shiny as 'Park Farm Hybrid'. A plant

at Wakehurst Place, England, was 5' high and wide with leaves like *V. carlesii*: rounded, serrated, and entirely deciduous, April 20, 1999. Plants to 12' high have crossed my path, causing me to suspect that some 'Anne Russell', so tagged, may not be true to form. Will flower in late March–early April in Athens. In January 2006, we acquired 'Anne Russell' from Piedmont Carolina Nursery for our Chapel Hill garden; it performs and looks like the real thing. A plant at Hillier in 1999 was dense, 5' high and wide, with some leaf spot.

'Carlotta'—Derived from the same backcross as 'Anne Russell' and introduced by W. B. Clarke, San Jose, California. Considered an improved *V. carlesii* with larger broad-ovate leaves. I have been unable to track this in cultivation.

'Chenaultii'—Listed as *V. ×chenaultii* and, on occasion, shows in the literature as such. Leaves are lustrous dark green, slightly smaller, and more refined than *V. ×burkwoodii*. White flowers average 2 to 3" diameter, slightly pink in bud opening white, and fragrant. The branches are fine-textured, and the overall habit quite refined. Will grow 10' high. Plants that large grew at Callaway Gardens, Pine Mountain, Georgia; in England, 7 to 8' was the tallest I witnessed. Raised in France.

'Compact Beauty'—Listed by the Dawes Arboretum, Newark, Ohio. No additional information available.

'Conoy'—A terrific hybrid, and Bonnie and I have lovingly appreciated its stellar performance in our Athens garden. Habit is compact, 5 to 6' high, 6 to 8' wide. The foliage is exquisite—a polished dark green, slightly wavy-surfaced, cupping in the cold of winter, 1 1/2 to 2 1/2" long. Pink buds open to white, essentially nonfragrant flowers in early April (Athens) and are followed by 1/3-inch-long glossy ovoid drupes in late summer that change from red to black. This magnificent garden plant was bred by Don Egolf, U.S. National Arboretum, using *V. utile* × *V. ×burkwoodii* 'Park Farm Hybrid', and introduced in 1988 (for a full description, see Egolf, Donald R. 'Conoy' *Viburnum*. *HortScience* 23:419–421 (1988)). Cross made in 1968, selected in 1976, named and released in 1988. Continues to grow in stature and prominence among commercial nurserymen and gardeners. Displays superb drought tolerance once established. Witnessed spectacular red fruit on plants at Swarthmore College in 2007.

'Fulbrook'—Same parentage (supposedly) as 'Anne Russell' with large, sweet-scented, pink-budded flowers that open white. Each flower is 3/8" wide, the cymes 3" across. Matures 8' high by 10' wide. Leaves are like *V. carlesii* with more luster, strongly serrated, 3 to 4" long and 2 to 3" wide. The few plants I observed do not measure up to 'Mohawk' and 'Park Farm Hybrid'. I thought the foliage on the plant at Hillier was inferior to that of *V. carlesii*. Raised by Florence Paget, distributed by Douglas Garden, Fulbrook House, Elstead, Surrey, England. The Hillier plant was 5' high and wide in 1999. The more I observe this and 'Anne Russell', the more confused I become. I suspect a mix-up. Typical plants of 'Anne Russell' are always better than the best specimens of 'Fulbrook'.

'Mohawk'—Result of the genius of Egolf, who backcrossed *V. ×burkwoodii* × *V. carlesii* in 1953, selected this taxon in 1960, and released it in 1966. Embryo culture was used to expedite seedling growth. Shining dark red buds open to white petals with red-blotched reverse. The fragrance is heavenly. Inflorescences average 3 to 3 1/2" (4") across and are prime in early to mid April (Athens); full flower April 6, 2004 at the JC Raulston Arboretum, Raleigh, North Carolina. Flowers are abundant. Leaves are glossy dark green, turning orange-red to red-purple in mid November (Athens) and abscising clean by late November. The habit is rounded to broad-rounded, typically 7 to 8' high, although I have seen plants over 10' high. My experiences and observations elevate 'Mohawk' to the Top 5 aristocrats among fragrant viburnums.

'Park Farm Hybrid'—In the genuine incarnation, is a choice garden plant. Unfortunately, it is confused in U.S. commerce. I researched its identity throughout gardens and nurseries, never positive that I had the real McCoy in my sights. At Hillier Arboretum, the genuine article showed its true brilliance. Raised in 1924 by Burkwood and Skipwith, a sister seedling of *V. ×burkwoodii*, it has larger leaves that are evergreen (completely so at Hillier), lustrous dark green, 3 to 4" long, entire or slightly serrated. The leaves are narrow-ovate-elliptic, not as round as the other *V. ×burkwoodii* types and consistently longer. The widest leaf measured by the author was 1 3/8" by 3 1/8" long. The deep pink buds open to fragrant white flowers in 3 to 5" wide inflorescences. Often listed as more compact than typical *V. ×burkwoodii* and wider than high. My notes state 8 to 10' high and wide (Hillier), 10' high and 8' wide (RHS Wisley), 10' high and 15' wide (Hillier). All abundantly endowed with flowers, which persisted for two weeks. In full flower April 19, 1999 at Hillier. I was fortunate to root cuttings of the outstanding Hillier form and now have the plant in our Georgia trials. It is being used in hybridization work with *V. utile* and *V. macrocephalum* f. *keteleeri*. The first generation seedlings of 'Park Farm Hybrid' × f. *keteleeri* were

deciduous to evergreen, small to large leaved, glossy to dull surfaced. All have flowered and only one seedling passed the initial screening use.

'Sarcoxie'—Result of a backcross of *V. ×burkwoodii* × *V. carlesii* by Dale Wild of Sarcoxie Nursery, Missouri. Described as upright in youth, more rounded with maturity, fragrant flowers 2 to 3" across. I have never observed this cultivar.

PROPAGATION: In general seeds of viburnums are not the easiest to germinate; they show a double dormancy and require warm/cold periods of different duration; 3 to 5 months warm followed by 3 months cold is sufficient for many; it is best to place the cleaned seeds in warm stratification and watch for radicle emergence; when this occurs the seeds should be transferred to the cold. I have rooted cuttings from June–July collected wood with 100% efficiency; cuttings were dipped in 1,000 ppm IBA/50% alcohol solution; in general, cuttings of most viburnums are easy to root although some taxa, particularly the fragrant, semi-snowball types, experience overwinter survival problems. See Dirr and Heuser (2006) for a good discussion.

ADDITIONAL NOTES: The species was developed in England by Albert Burkwood and Geoffrey Skipwith in 1914 and introduced in 1924. It is a cross between *V. carlesii* and *V. utile*, the latter having proved to be of little worth as a garden shrub but a fine parent in breeding programs.

RELATED SPECIES:

***Viburnum utile* Hemsl.** — Service Viburnum
(vī-bēr'num ū'ti-lē)

LEAVES: Opposite, simple, ovate to oblong, 1 to 3" long, 1/4 to 1 1/4" wide, obtuse, rarely acutish, broad-cuneate or rounded, entire, leathery, lustrous dark green and glabrous above, prominently veined (5 to 6 pairs) and white beneath with a dense covering of stellate hairs; petiole—1/6 to 1/3" long.

Viburnum utile, Service Viburnum, is a small, 4 to 6' high and wide, evergreen shrub of rather straggly habit. The leaves have a rather wavy and at times almost inrolled (revolute) appearance. The pink-budded, essentially none to slightly fragrant, white flowers occur in mid-April (Athens) to May in 5-rayed, 2 to 3" diameter, rounded cymes. The fruit is a 1/4" long, bluish black drupe. This species has been most important in breeding work and has given our gardens *V. ×burkwoodii* and its cultivars, along with *V. ×pragense*. The species is seldom seen in gardens and is not the handsomest of plants owing to the open habit, small leaves and rather nondescript flowers. However, it carries genes for heat tolerance and old plants at Callaway Gardens and in Aiken, SC attest to this. Also, the fine glossy foliage character appears often in the off-spring. A small plant in our garden reminds one of the power of the great plant breeders. Our gardens are blessed because certain individuals see and seize the future. I have three different forms with varying leaf sizes and habits. The best yet grows in the garden of Hillary Barber, Athens, GA. Leaves are lustrous black-green, extremely small, narrow-ovate. The habit is akin to *Cotoneaster dammeri*. Worthy of a name. Central China. Introduced 1901. Zone 6 to 8.

***Viburnum carlesii* Hemsl.** — Koreanspice Viburnum
(vī-bēr'num kār-lēs'sē-ī)

LEAVES: Opposite, simple, broad-ovate to elliptic, 1 to 4" long, 3/4 to 2 1/2" wide, acute, usually rounded to subcordate at base, irregularly toothed, dull dark green to somewhat sheeny and stellate pubescent above, densely so and paler beneath; petiole—1/4 to 1/2" long.

BUDS: Vegetative—foliose, naked, hairy; flower buds large—1/4 to 1/2" wide.

STEM: Light brown to gray, stellate pubescence on young stem; old stems are gray and exhibit a characteristic fissuring.

SIZE: 4 to 5' possibly to 8' in height, by 4 to 8' in width, have seen plants 10' high and wide, the more I travel the garden path the larger the specimens I see.

HARDINESS: Zone (4)5 to 7(8); injured in Orono, ME; fine at Morton Arboretum.

HABIT: Rounded, dense shrub with stiff, upright spreading branches.

RATE: Slow.

TEXTURE: Medium in summer and winter, clean in appearance.

LEAF COLOR: Dull dark green with a satiny sheen, very pubescent on the upper surface, more so on lower, reddish to wine-red in fall color, not consistent in coloration and usually disappointing, fall color on occasion is excellent prompting thoughts of clonal selection; Matt Vehr, former horticulturist, Spring Grove, showed me slides of a rich red-purple fall-colored form.

FLOWERS: Perfect, pink to reddish in bud, opening white, each individual flower 1/2" across; late April to early May, late March to early April in Athens; in dense hemispherical cymes, 2 to 3" across, often termed semi-snowball type flowers; flowers are at their best when leaves are 1/2 to 2/3's mature size; fragrance almost like *Daphne odora*, truly outstanding.

FRUIT: Drupe, 1/3" long, egg-shaped, flattened, red changing to black (not effective), August to September.

CULTURE: Transplant balled-and-burlapped, container-grown, or as a small bare root plant; best in well-drained, slightly acid soil with even moisture; full sun to partial shade; prune after flowering; plants were grafted on *V. lantana* and I have seen the scion consumed by the understock; be careful to buy own-root plants.

DISEASES AND INSECTS: Bacterial leaf spot can be troublesome; nematodes infect this species; noted abundant aphids on plants in Rockport, ME in late May.

LANDSCAPE VALUE: A valuable shrub for fragrance; I used it in a foundation planting along a walk at my Illinois home and for ten days in late April-early May it was a joy; some of the newer cultivars and *V. xjuddii* are superior and should be used in preference; not as adaptable as *V. xjuddii* or *V. xburkwoodii*; in Wichita, KS the species is common and successfully cultured in high pH soils and wind-swept conditions.

CULTIVARS: At the Hillier Arboretum, the Slieve Donard Nursery, County Down, Ireland, introductions 'Aurora', 'Charis', and 'Diana' were carefully studied. These selections resulted from the work of Leslie Slinger, who imported seed from Japan and introduced the three cultivars in 1958.

'Aurora'—An excellent selection that first attracted my attention during my 1991 sabbatical at the Arnold Arboretum. The Arnold plant was 6 to 8' high and wide. Rich deep pink-red buds open to pinkish white, spicily fragrant flowers. Inflorescences are larger—to 5"—and more substantial than those of the species. It is starting to appear in U.S. nurseries. A 6' by 7' plant at Hillier, somewhat scraggly in outline, had some leaf spotting, although leaves were green at emergence.

'Arlene'—Listed by the Dawes Arboretum, Newark, Ohio.

'Charis'—Vigorous form, probably larger than 'Aurora' at maturity. Red-budded flowers open to pink and at maturity are white. Highly fragrant. Not impressive at Hillier: loose, open, bedraggled, 6' high and wide in 1999, with rounded, toothed leaves and smaller flowers than 'Aurora'.

'Compactum'—Superb dwarf selection that matures 3 to 4' high and wide with dark green leaves and flowers about the same size as the species. Displays greater resistance to bacterial leaf spot. Introduced by Hoogendoorn Nurseries, Newport, Rhode Island, in 1953.

'Diana'—Vigorous clone of relatively compact habit that is red in bud, opening the same and finally turning pink, and fragrant. Purple-tinged young foliage and young stems and petioles are reddish purple. This is arguably the finest of the Slieve Donard introductions. I witnessed a dense, 6 by 8' specimen at Hillier in 1999 with excellent foliage and no leaf spot.

'Marlou'—Introduced by Ward van Teylingen, Boskoop, Netherlands.

Spice Island™ ('JNSA')—Red-pink buds, white flower; satiny dark green leaves, red-purple in fall; 3 to 5' by 3 to 5', compact like Hoogendorn's; roots from cuttings; Michael Yanney selection, Johnson's Nursery.

Spiced Bouquet™ ('J. N. Select')—Produces dark rose-pink buds that open to soft pink flowers. It has a compact habit, growing to 5' high and 6' wide in ten years with good foliage density. Leaves have a pronounced glossy sheen. Selected by Michael Yanney in the late 1980s. Introduced by Johnson's Nursery, Menomonee Falls, Wisconsin.

Sugar 'n' Spice™ ('Select S')—Abundant flowers in smaller inflorescences, fine textured, healthy, dark green leaves, wine-red to maroon fall color; typical habit, 5' by 5' in 5 years; Michael Yanney selection, Johnson's Nursery.

'Variegata'—Listed by Kenyon (2001) as a slow-growing variegated form. I have not observed it; have observed photos of a yellow-leaf-splashed variation that was selected by Gary Ladman.

PROPAGATION: Generally considered difficult but June–July cuttings treated with 8,000 ppm IBA-talc rooted 80% and all were successfully transplanted after going through a dormancy cycle; this is one of those plants that dislikes root disturbance after rooting. Several wide crosses with *V. lantana* were constructed at University of Wisconsin with embryo rescue being utilized to generate plants; see *J. Environ. Hort.* 13(4):193–195 (1995) for exciting possibilities; later crosses between the best seedlings have yielded about 10 promising selections that are still being evaluated (2007) by Dr. Brent McCown.

NATIVE HABITAT: Korea. Introduced 1812.

RELATED SPECIES:

***Viburnum bitchiense* Mak.** — Bitchiu Viburnum
(vī-bēr'num bitch-i-ū-en'sē)

LEAVES: Opposite, simple, ovate to oblong, 1 to 3" long, 1/2 to 3/4" wide, obtuse, subcordate to cordate, dentate especially toward apex, dark green above, pubescent on both surfaces, 6 to 7 vein pairs; leaves pubescent to degree of being gray-green rather than dark green on a single plant in the Georgia trials.

Viburnum bitchiense, Bitchiu Viburnum, is somewhat similar to *V. carlesii* but with smaller leaves, more slender stems, looser habit and smaller pinkish white flowers (1 1/2 to 2"(3") across) in looser clusters. Bitchiu is considered inferior to *V. carlesii* but selected forms may rival Koreanspice. Height varies from 8 to 10', similar spread. The dark bluish green foliage may turn dull reddish purple in fall but is usually not effective. The red, changing to black, fruit is produced sparsely. Bitchiu has imparted some of its good characteristics to *V. xjuddii*. Keep looking for definitive ways to separate this from *V. carlesii*. The looser, laxer, more open inflorescence and stronger dentate serrations toward apex of the leaf are helpful. Have observed worthy, robust specimens of *V. bitchiense* that rival *V. carlesii*. A wild-collected seedling in the Georgia trials, collected by Dan Hinkley, has larger rich pink buds, opening white, fragrant, to 4" diameter. Superb sheeny blue-green leaves and in 2006, developed red-maple fall color. Taxonomists might discourse whether *V. bitchiense* is really different from *V. carlesii*. Japan, Korea. Cultivated 1909. Zone 5 to 7.

***Viburnum xcarlcephalum* Burkw. ex R.B.**

Pike, (vī-bēr'num kārī-sef'a-lum),
Carlcephalum or Fragrant
Viburnum, grows 6 to 10'(15')

high with an equal spread.
Habit is somewhat open
and loose. Foliage is dark
green with a slight luster in
summer changing to reddish
purple in fall. Leaves are the
largest of the fragrant, semi-
snowball group, often 4 to 5" long.

The flowers are pink in bud, finally
white, fragrant, late April to early May,
borne in 5 to 6" diameter, up to 100-flowered,

hemispherical cymes. In full flower from late March to early April in Athens. One of the best descriptions I read termed the inflorescences lumpy. Fruit is a drupe which changes from red to black; however, it is seldom effective. Have collected handfuls of fruits and germinated with the small seedlings appearing similar. Two-year-old plants showing differences, some with lustrous dark green foliage and developing flower buds. Reasonable plant for the garden. Result of a cross between *V. carlesii* × *V. macrocephalum* var. *keteleeri*. Originated in England in 1932 at the Burkwood and Skipwith Nursery and introduced into the United States about 1957. It is relatively easy to root from softwood cuttings. It is the latest of the semi-snowball types to flower. Usually somewhat coarse and in no way as fine a garden shrub as *V. xjuddii*. Have seen on occasion in the South and was pleased with floral performance. Hardiness is somewhat suspect and a Zone (5)6 to 7(8) rating is safest. An 11' high plant was reported at the Morton Arboretum (Zone 4/5).

CULTIVARS:

'Cayuga'—An Egolf introduction that resulted from a backcross of *V. carlesii* × *V. xcarlcephalum* in 1953. A superior seedling was selected in 1960 and named in 1966. In general, the plant in all its parts is smaller than *V. xcarlcephalum*, although this is somewhat misleading, as I have observed 10-foot-high plants. Leaves are darker green with a bit more polish than the species. I measured leaves 5" long, 2 3/4" wide, toothed, pubescent on both surfaces, with a 1/4-inch-long, pubescent petiole. Wonderful orange-red fall color has occurred in Athens. Flowers, 4 to 5" across, are pink in bud, opening white, and fragrant. In full flower April 29, 2005, Swarthmore College, Pennsylvania; April 15, 2004, Hickory, North

Carolina. In youth, the habit is distinctly upright, spreading with time, and becoming somewhat leggy. Hardiness is similar to the species, perhaps slightly greater. Plant was 8 1/2' high and 11' wide at 20 years.

'Chesapeake'—As is true for 'Eskimo', appears to belong with *V. × burkwoodii* because of the foliage characteristics. Egolf crossed 'Cayuga' with *V. utile* in 1962 and introduced 'Chesapeake' in 1981 (see Egolf, Donald R. 'Chesapeake' viburnum. *HortScience* 16:350 (1981)). 'Chesapeake' has lustrous dark green wavy leaves and 2" wide, pink-budded flowers that open white, with minimal (no) or ever-so-slight fragrance. Flowers open after *V. × carlcephalum* in early to mid April (Athens). Fruits are dull red to black and seldom abundant. Size is larger than the 6' high and 10' wide in 16 years that was originally cited. Plants reach 10' high and wide or greater. I witnessed an 8' by 8' plant at Savill Gardens, England, on April 14, 1999; a 10 to 12' high and slightly wider plant on the Georgia campus, May 20, 2006. Branches are brittle and difficult to tie up during the balling and burlapping process. The flowers pale by comparison with its sister seedling 'Eskimo', and it is not as cold hardy, probably surviving to -15°F.

'Chesapeake'

'Eskimo'—Appropriately named for the white snowball flowers that dot the plant in early to mid April (Athens). Pale cream buds, etched with pink, open pure white, each inflorescence 3 to 4" in diameter and nonfragrant. The lustrous dark green leaves are flat surfaced, a reliable trait that permits separation from 'Chesapeake'. The leaves are more evergreen than 'Chesapeake'. Habit is upright in youth, oval-rounded with maturity, approaching 8 to 10' in height. This is the real deal in flower and makes a great show in the shrub border. 'Cayuga' was crossed with *V. utile* in 1962; a selection from this cross was selfed in 1967. A seedling was selected for evaluation in 1975 and introduced as 'Eskimo' in 1981. See Egolf, Donald R. 'Eskimo' viburnum. *HortScience* 16:691 (1981).

'Eskimo'

'Variegatum'—Listed, but I have only witnessed 'Maat's Select', an unstable gold-cream-green leaf form named for Dick van der Maat, Boskoop, Netherlands.

***Viburnum ×juddii* Rehd.**, (vī-bēr'num jud'ē-ī), Judd Viburnum, is the result of a cross between *V. carlesii* and *V. bitchiuense* with the best features of both parents. I feel it is superior to run-of-the-mill *V. carlesii* and may eventually replace it in northern and southern areas. The habit is full and rounded with mature height approaching 6 to 8'. It is more resistant to bacterial leaf spot and roots much more readily from softwood cuttings. The inflorescence ranges from 2 1/2 to 3 1/4" wide and when open is highly fragrant. I have heard people say that the fragrance of *V. ×juddii* is not as pronounced as that of *V. carlesii* but am hard-pressed to distinguish between the two. This hybrid was raised at the Arnold Arboretum by William H. Judd, propagator, in 1920; flowered for the first time in 1929 when it was 6' high and named in 1935. Nurserymen are selling this hybrid in greater numbers and someday it may replace *V. carlesii* as the dominant semi-snowball viburnum. Zone 4 to 8. Has proven an adaptable and floriferous shrub in the University's Botanical Garden. It is located by a walk that leads from the parking area and many people stop to sample its delicious perfume. The plants are now over 10' high. Flowers in late March–early April in Athens.

***Viburnum macrocephalum* Fort.** — Chinese Snowball Viburnum
(vī-bēr'num mak-rō-sef'a-lum)

LEAVES: Opposite, simple, deciduous or semi-evergreen, ovate or elliptic to ovate-oblong, 2 to 4" long, 1 1/4 to 2 1/2" wide, acute or obtusish, rounded at base, denticulate or entire, dark green and nearly glabrous above, stellate-pubescent beneath; petiole—1/2 to 3/4" long.

Viburnum macrocephalum, Chinese Snowball

Viburnum, is a dense, rounded shrub growing 6 to 10' high in more northerly climes. The flowers are white, non-fragrant, each individual floret 1 1/4" across, May to early June, (mid-April in Athens), borne in 3 to 8" diameter hemispherical cymes. Extremely showy in flower but requires a protected location and well-drained soil. I have seen it flowering in Columbus, OH, in a protected area. The foliage is semi-evergreen in the South. In the southern states the plant may grow 12 to 15'(20') high and form a massive rounded shrub. It tends to flower in the fall during warm weather in the South. In full flower it is a spectacular

shrub and certainly worthy of consideration in larger gardens. For many years, it was been a staple in the entrance planting to our home. Every 3 or 4 years I cut it 2 to 3' from the ground because of its tendency to overgrow the surrounding vegetation. First year after cutting back, there are no flowers, subsequent years unbelievable profusion. Interestingly, the showy florets are apple green when emerging, finally white. People stop to ask the identity of the plant. Great for obtrusive show. It is relatively easy to root from June–July cuttings using 3,000 to 5,000 ppm IBA-quick dip but resents disturbance after rooting and should be left in place until the second year. Does not fruit as the flowers are sterile. China. Introduced 1844. Zone 6 to 9.

Forma *keteleeri* (Carr.) Rehd. is the wild type with fertile and showy, nonfertile flowers in a lace-cap configuration. Foliage is similar to *V. macrocephalum*. The white, slightly off-odor flowers open in early April (Athens) in 4 to 5" wide, flat-topped cymes. The shiny red to black, oblong, 1/2" long fruits are beautiful. Easily 10 to 15' high and larger. Witnessed a 17' by 14' specimen at Hillier, July 1, 1999. Native to China. Introduced about 1860. This was used to produce *V. xcarlcephalum* (*V. carlesii* × *V. m. f. keteleeri*). Egolf crossed f. *keteleeri* with 'Eskimo' in 1988, which resulted in a dense, broadleaf evergreen shrub with large white irregular, cloud-like inflorescences of fertile and sterile flowers in early to mid April (Athens). In full flower April 6, 2006 (Athens). This hybrid, selected by Ruth Dix and Margaret Pooler in 1997, National Arboretum 69852 (now 'Nantucket'), has proven outstanding in the UGA tests and displays superior heat and drought tolerances. Has consistently (five years) maintained all its foliage through the winter. Grew to 6 1/2' by 4' in five years; original plant 12' by 7'. Seedling populations of 'Nantucket' have segregated to compact/large, evergreen/deciduous, fragrant/non-fragrant and repeat flowering. Exciting plants in this mix with several worthy of introduction. 'Nantucket' has consistently set astronomical numbers of flower buds year-in, year-out. It receives no supplemental irrigation and, in 2007 and 2008, two of the hottest and driest years on record in Athens, performed magnificently.

Viburnum cassinoides L. — Withered Viburnum, Swamp Viburnum, Appalachian Tea

Viburnum, Swamp Blackhaw, False Paraguay Tea, Wild Raisin

(vī-bēr'num kas-i-noy'dēz)

LEAVES: Opposite, simple, elliptic or ovate to oblong, 1 1/2 to 3 1/2"(4 1/2") long, 3/4 to 2 1/4" wide, acute or bluntly acuminate, rounded or wedge-shaped, obscurely dentate or denticulate, bronze-to chocolate-tinted in youth, dull dark green above, nearly glabrous, somewhat scurfy beneath; petiole—1/4 to 3/4" long, scurfy.

BUDS: Valvate, flowers with a bulbous base terminating the shoots, similar to *V. lentago*; vegetative—long, narrow, without the fattened base.

STEM: Gray to brown, scurfy in youth, finally glabrous.

Viburnum cassinoides grows 6 to 10' tall with a similar spread. It is a handsome dense shrub, compact and rounded, with spreading, finally slightly arching branches. The dull dark green foliage changes to orange-red, dull crimson, and purple in fall. The emerging leaves are often bronze- or purple-tinted. The flowers are creamy white, June to early July, borne in 2 to 5" diameter, flat-topped, arching at extremities cymes. Each flower is about 1/5 to 1/4" diameter and the yellowish stamens create a soft yellow patina over the entire inflorescence. The fruit is the most beautiful attribute as it changes from green to pink, then from red to blue before becoming black in September. Often all colors are present in the same infructescence (fruiting cluster). A very lovely but little used shrub which has a place in naturalizing, massing, and the shrub border. I have seen it used effectively in a mass planting at the Holden Arboretum, Mentor, OH. In Maine, I saw it growing along the roadside and while trekking the highest mountain in Georgia discovered it in full fruit all along the route. Many plants I have observed in the wild were in the 12

to 15' range although most books do not allow the species to grow over 12'. This is a fine viburnum and in fruit is spectacular. Considerable variation would allow for selection of flower, fruit, foliage and habit. I am on patrol and eventually will have a worthy clone or three. Newfoundland to Manitoba and Minnesota south to Georgia. Introduced 1761. Zone 3 to 8.

Cultivars:

Buccaneer™ and Defender™—Listed, but I was unable to locate descriptions.

Challenger™ ('KLMC')—Clean, dark green foliage, orange, red, purple in fall; pink-blue-black fruits; 5 to 6' by 5 to 6' in 5 years; Roy Klehm selection for the Midwest.

'Deep Pink'—Described by Connecticut nurseryman Mike Johnson, Summerhill Nursery, as a deep pink-fruited form that he discovered in Maine.

Hillier Form—A yet untitled clone that botanist Allen J. Coombes was considering naming. Young leaves emerge in early April (Athens) a rich, shiny, deep chocolate-purple. The large dark blue-green leaves turn deep mahogany-purple in fall. Typical white flowers and beautiful robin's-egg blue fruits. This is a large form, easily reaching 10' high and 12' wide and beyond.

'Nanum'—Dwarfish mound of crinkled, crisped, convex leaves that emerge bronze, deepening to green. Leaves are larger than the species, up to 5" by 3". It is a slow-growing and small plant that in our tests did little to impress. Flowering has not been reported. The largest plants in the author's purview grew at the Hillier Arboretum and were 2 1/2' high by 3 to 4' wide.

'Sear Charm'—Similar to 'Royal Guard' with narrower leaves and smaller stature; buds and leaves, when emerging, appear similar to *V. cassinoides*; when fully open look quite different; description per Chris Pattison, Gloucestershire, England.

'Summer Hill' is listed as a hybrid with shiny green leaves that may stay green in warm climates. Matures 5 to 6' high. Offered by the former Roslyn Nursery.

A closely related species, *Viburnum nudum* L., (vī-bēr'num nū'dum), Smooth Witherod, is equally beautiful and perhaps more so because the leaves are more lustrous. The leaves and stems may also be less pubescent but this appears to be somewhat variable. I grew this species in my Illinois garden where it survived -20°F. The red to reddish purple fall color is also attractive. With selection this could become a well-received garden plant. Current thinking merges *V. nudum* under *V. cassinoides*. For purposes of discussion, I have kept them separate. Those previous comments aside, Meyer, Mazzeo and Voss, *A Catalog of Cultivated Woody Plants of the Southeastern United States*, USDA-ARS, USNA Contribution No. 7 (1994), *The New RHS Dictionary of Gardening* (1992), Hillier Manual (2002), GRIN and RHS Plant Finder 2008–2009 maintain species status. As I grow wiser and more skeptical, I realize that almost everything in nomenclature comes full circle. The question remains whether I can outlast the taxonomists. See *Nursery Management and Production* 14(1):14–15, 72 (1998) for an update on my emotional bonding with the above two species. National champion 33' by 20' in Oconee, GA. Connecticut, Long Island to Florida, west to Kentucky and Louisiana. Introduced 1752. Zone 5 to 9.

*Viburnum
nudum*

Cultivars:

var. *angustifolium* Torrey and Gray—Smaller, narrower leaves (2 to 3" by 1") and smaller stature than the species. My initial reaction to the plants trialed at UGA was "Where's the beef?" Young plants were open, and the foliage was not as sheeny as that of the typical species. At five years of age, plants are more dense, and the red-purple, long-persisting fall color is a great bonus. Perhaps hasty in my judgment. Flowered later than the species and 'Pink Beauty'. Full flower, early May 2009 (Athens). Produced lovely pink to blue fruit in copious quantities. I walked my UGA viburnum trials on June 8, 2006 and was impressed with the 8' by 6', densely foliated specimen. The finer-textured leaves make it distinct from the species.

Brandywine™ ('Bulk')—Described as a heavy-fruited selection, 5' high and wide, from Mark Bulk in the Netherlands. The fruits are produced in shades of green, pink, and blue. I have yet to see the plant but have doubts about the 5' height. Also, the fruits on most *V. nudum* are the same color. Time will tell if it is unique. The plant is listed as PPAF. I have yet to witness a *V. nudum* produce more fruits than 'Pink Beauty'.

'Count Pulaski'—A multi-stemmed, loosely structured form with rapid growth. Larger leaf than typical, almost glossy. Extremely floriferous with white, musky-scented flowers. Fruits are borne in 6' to 10' wide, flat-topped cymes in colors that range from green to exotic salmon-pink to shades of lavender, to blue and purplish black. A lone plant in the great garden of Coach Vince Dooley, Athens, Georgia, has grown tall, lanky, and open. Fruits have not paralleled the description above. 'Earth Shade', 'Pink Beauty', and 'Winterthur' are superior. The original plant was collected in Pulaski County, Arkansas, and introduced by Larry Lowman.

'Earth Shade'—Glossy dark green leaves take on hues of yellow, orange, and red in autumn. More compact than 'Winterthur' but in the 6 to 10' range. Typical cream-white flowers, pink to blue fruits of the species.

Original plant was given to me by William Flemer of Earth Shade Nursery, Warne, North Carolina. I considered it superior to run of the mill seedlings and named it after Bill's former nursery.

'Moonshine'—Glossy green leaves; have observed only once, nothing spectacular; am unsure of origin.

'Pink Beauty'—Has remained relatively compact in our Chapel Hill, North Carolina, garden and set abundant fruit without another pollinator. Leaves are absolutely stunning, glossy dark green in summer, developing red-purple autumn hues. Flowers opened fully on May 23, 2006 in Chapel Hill. Fruits start pink, mature to blue-purple-black, and were still present on April 4, 1999 as the new bronzy leaves are pushing forth. See Dirr, *NMPro* 25(9):6 (2008).

'Winterthur'—An improved form selected at the Winterthur Garden, Delaware. Killed the first one in Georgia, added another, and it grew well, with lustrous, waxy foliage, compact, 6' in ten years. A planting at Longwood Gardens was 10' high, rather open, in late April 2005. Red fall foliage and abundant blue fruits were evident on the Longwood plants on September 29, 2002.

Viburnum davidii Franch. — David Viburnum

(vī-bě'rnum da-vid'ē-ī)

LEAVES: Opposite, simple, evergreen, narrowly oval or slightly obovate, 2 to 6" long, 1 to 2 1/2" wide, acuminate, cuneate, conspicuously 3-veined, toothed toward apex, leathery, lustrous dark green, almost dark bluish green above, pale beneath, glabrous except for axillary tufts of hair below; petiole—1/4 to 1" long.

Viburnum davidii forms a low, compact, 3 to 5' high mound of thick, dark blue-green evergreen foliage. It is a beautiful viburnum and if it never flowered or fruited it would still be a plant of the first order. I have seen it in abundance throughout Europe. In Athens, GA and Aiken, SC where I observed plantings, it is still subject to the vagaries of weather and the flowers and leaves may be injured. It appears to require a more moderate, even climate than can be offered in most parts of the United States. Ideally it is suited to the Pacific Northwest. The pink-budded, finally dull white flowers occur in dense, 2 to 3" wide, 7-rayed cymes in April–May. The 1/4" long, oval fruits are a beautiful shade of blue. Unfortunately, the plant is either functionally dioecious or requires cross pollination from another clone for fruit is not set unless the proper conditions are met. In England, clones have been designated "male" and "female." The plant in fruit is spectacular and the first impulse is to locate a source for one's own garden. I have seen the plant used in combination with other broadleaf evergreens and it was effective. The Isle of Mainau in Germany has several large specimens. 'Jermyns Globe' is now considered a hybrid of *V. davidii* × *V. calvum* (*V. xglobosum* Coombes) and the original plant, compact and rounded, was 12' by 12'. Also, occasionally growing and seemingly more contentedly, is *V. cinnamomifolium* Rehd., that is larger, 6 to 10'(20') high and apparently more cold hardy (Zone 7). There is a relatively respectable specimen at the Atlanta Botanical Garden. Woodlanders, Aiken, SC reported this a better doer than *V. davidii*. Shaky for all but the collector. China. *Viburnum davidii* is native to Western China. Introduced 1904. Zone (7)8 to 9.

CULTIVARS:

'Angustifolium'—A narrower leaf form with the same traits as the species but a more refined appearance. In habit, as I first witnessed the plant (1999), it was compact and spreading. The same plant was 5 to 6' high and looser and more open as viewed in March 2006. I have read mention that it may be a hybrid between *V. calvum* and *V. davidii*, although I see no *V. calvum* in the gene pool. It is faster growing and flowers slightly later than *V. davidii*. May be closer to *V. cinnamomifolium*. Origin unknown. Certainly would be worth testing for adaptability in the United States since the leaf texture is similar to *V. davidii* and *V. cinnamomifolium*.

Viburnum dentatum L. — Arrowwood Viburnum

(vī-bě'rnum den-ta'tum)

LEAVES: Opposite, simple, suborbicular to ovate, 2 to 4 1/2" long, 1 to 4" wide, short acuminate, rounded or subcordate, coarsely dentate, lustrous dark green and glabrous above, glabrous beneath or bearded in the axils of the veins, with 6 to 10 pairs of impressed veins; petiole—1/2 to 1" long.

BUDS: Imbricate, usually appressed, green to brown, small, lower bud scale forming a V-shaped notch, glabrous, almost glossy.

STEM: Glabrous at maturity, gray to gray-brown, leaf scars with ciliate hairs around the margins.

SIZE: 6 to 8' to 15' in height in favorable locations, spread 6 to 15'.

HARDINESS: Zone (2)3 to 8.

HABIT: Multi-stemmed, dense, rounded shrub with spreading, finally arching branches, suckering tendency and will colonize.

RATE: Medium.

TEXTURE: Medium in leaf and winter habit; some specimens are so delicately branched as to appear medium-fine in winter.

LEAF COLOR: Lustrous dark green in summer, sometimes without the sheen, fall color ranges from yellow to glossy red to reddish purple; selections for superior clones both in habit and foliage have been introduced (see CULTIVARS); I have seen poor fall-colored specimens growing next to brilliant glossy red forms; the differences were not attributable to soils or climate but genetics.

FLOWERS: White, actually yellow stamens create a creamy color rather than pure white, somewhat ill-scented, occasionally no scent, May to early June, early May (Athens), effective 10 to 14 days, borne in 2 to 4" (5") diameter, flat-topped, 7-rayed cymes on 1 1/2 to 2 1/2" high, raised peduncles; May 15 to 25, 2007 and 2009, full flower in Chapel Hill, NC area.

FRUIT: Drupe, oval-rounded, 1/4" long, blue or bluish black, late September through October; birds relish the fruits and seeds are found germinating in many out-of-the-way places; some plants have particularly striking blue fruits, actual seed (stone) has a narrow deep groove on one side.

CULTURE: Fibrous rooted, transplants well, adapted to varied soils (possibly most durable viburnum for East and Midwest), prefers well-drained conditions; sun or partial shade; suckers freely from the base and may have to be restricted from getting out of bounds; observed growing at water's edge so more wet soil tolerant than credited.

DISEASES AND INSECTS: In North, the Viburnum beetle has ravaged the species; otherwise I have not noticed significant problems.

LANDSCAPE VALUE: Valued for durability and utility, the ornamental characters are secondary to other viburnums, good in hedges, groupings, masses, filler in shrub border; University of Illinois effectively employed this shrub for screening parking lots; its utilitarian and adaptable nature is readily evident for I have observed it growing in the sands of Cape Cod, not too far removed from the salt spray, but never forming the first or second line of defense; in Nebraska it withstands the high pH, heavy soils and the vagaries of that climate; without a doubt it is one of the most functional viburnums; numerous cultivars introduced in the past 10 years; the landscape jury is still deliberating on the merits.

CULTIVARS:

Autumn Jazz® ('Ralph Senior')—Graceful, vase-shaped habit, 8 to 10' high, 10 to 12' wide, glossy green summer foliage, white flowers, and blue-black fruits. Fall color is yellow-orange-red-burgundy, and I observed it turning yellow-orange-red at the Chicago Botanic Garden on October 28, 1998. It has minimal fall color in Zone 7. A good-quality, 10' by 10' specimen grew at the Minnesota Landscape Arboretum on July 20, 2005. Introduced in 1992 through Chicagoland Grows® and selected by Synnesvedt Nursery, Round Lake, Illinois.

Black Forest™ ('KLMnine')—On Roy Klehm's Beaver Creek Nursery production/trial list.

Blue Blaze™ ('Blubzam')—Low spreading habit and moderate growth rate, and matures 5' high by 7' wide. Two to 4" wide, cream-white cymes occur in May–June followed by blue fruits. Attractive, 3" long, gunmetal-green leaves have deep wine-colored lower surfaces. This is a Lake County Nursery introduction, part of the Lake Erie Series™.

Blue Muffin™ ('Christom')—Glossy dark green leaves, intense blue fruits and grows 5 to 7' high, 2 to 4' wide. This form was listed as 4 to 5' high and wide in ten years but has grown 7' high in five years in Athens, Georgia. Selected by Tom Watson, Christom Farms Nursery, Cambridge, Wisconsin. Sold under the Proven Winners® banner.

Cardinal™—Light green leaves, brilliant red fall color, white flowers, 1/4" long, blue fruits on an upright 10 to 12' high and wide habit. In five years, no fall color in UGA trials. Hardy to Zone 4. Introduced by Roy Klehm, Beaver Creek Nursery, Illinois.

Chicago Lustre® ('Synnesvedt')—Glossy dark green foliage, white flowers, and blue-black fruits. Reddish purple in fall but not really striking; no appreciable fall color in Zone 7 (our *V. bracteatum* 'Emerald Luster' is superior). A 1990 Chicagoland Grows® introduction, Synnesvedt selection, that grows to be a rounded shrub 10' high and wide. I witnessed a 10' by 8' plant at the Minnesota Landscape Arboretum on July 21, 2005.

Cream Puffs™ ('Crpuzam')—Large, broad-rounded shrub maturing 10' by 12' with abundant white flowers, bright blue fruits, and red fall foliage. A Lake County Nursery introduction, Lake Erie Series™.

Crimson Tide™ ('KLMsix')—Clean summer foliage, blazing red fall color, exceptional vigor, and an upright habit similar to Autumn Jazz®. Grows 10 to 12' high and wide. Zone 4. Introduced by Roy Klehm, Beaver Creek Nursery.

var. *deamii* (Rehd.) Fernald—Larger leaves and flowers, shows up in collections. Eugene W. Coffman, Ridge Road Nursery, Bellevue, Iowa, lists it as one of the best forms of *V. dentatum*. It is a good representative for the Midwest of the terrific variation within *V. dentatum*. There was a loose, spreading

- shrub at Hillier, 10' high and wide, on July 1, 1999. Leaves are larger than *V. dentatum* with upper and lower surfaces extremely pubescent. Flowers are larger than *V. dentatum* with no odor.
- Dwarf Form—A selection that grew 5' high while others in seedling population were 8' high. Finer-textured branches and leaf size than species. Abundant cream-white flowers, reddish purple fall color, and blue-black fruit that is held above the foliage. Selected at Reeseville Ridge Nursery, Reeseville, Wisconsin. Also listed as 'Compactum', which is invalid.
- Fireworks™ ('Firzam')—Compact habit, 6 to 7' by 4 to 5', that is somewhat columnar in outline. Thick, glossy green leaves turn ruby-red in autumn. Produces cream-white flowers and blue-black fruits. A Lake County Nursery introduction, Lake Erie Series™.
- 'Golden Arrow'—Develops yellow leaves that may photobleach (turn white) and lose their color as they mature in Zone 7 and south. Leaves are smaller than typical *V. dentatum*. Shrub as viewed on April 9, 2006 at the JC Raulston Arboretum was not appealing. Discovered by Jon Roethling. I believe that this is the same as Yellow Leaf Selection.
- Grow Low™ ('GrowLo')—Listed by Beaver Creek Nursery.
- Indian Summer™ ('KLMeight')—Clean summer foliage and a blend of orange and red in the fall. It is an upright, rounded, vigorous form that grows 8 to 12' high and wide. Zone 4. Introduced by Roy Klehm, Beaver Creek Nursery.
- Little Joe™ ('KLMseventeen')—True compact form. Original plant was 4' high and wide after ten years. Finer-textured branches and smaller leaves than the species. Typical flowers and fruits. Purple-green fall color. Introduced by Roy Klehm, Beaver Creek Nursery.
- 'Moonglow' ('Moonglo', 'Moon Glow')—Rounded habit at maturity, low-spreading when young. Matures 8' high and wide. Inflorescences are cream-white, dome-shaped, rather than flat like the species. The stamens, as they mature, turn reddish, giving the appearance of cinnamon sprinkled on top of the flowers. Fruits are blue, larger than typical for the species, ripening in August–September. Leaves are rounded, lustrous dark green, with wavy margins and few serrations. Introduced by Moon Nurseries, Chesapeake City, Maryland.
- Northern Burgundy® ('Morton')—Dark green summer foliage that turns burgundy in fall. Grows 10 to 12' high, more upright than Autumn Jazz®. Same flowers and fruits as species, again nothing to get excited about in Zone 7. Chicagoland Grows® promotion, Synnesvedt introduction in 1992. A 10 to 12' high, quality specimen grew at the Minnesota Landscape Arboretum on July 20, 2005; it had duller and smaller foliage than Chicago Lustre®.
- 'October Glory' (PP 12,079)—Turns brilliant red in October and maintains the red color into November in Zone 5. Produces dense, flat, white clusters (cymes) of flowers in June that are effective for three weeks. Cold hardy and can withstand –20°F without damage. Introduced by William Flemer III, Princeton Nursery, Princeton, New Jersey.
- 'Osceola'—Selected by Rick Webb in the Florida parishes of Louisiana. Found growing at the edge of a pocasin (pine/holly forest) on clay hills. Slightly smaller foliage with late yellow-purple fall color. Good flower and fruit production. Original plant was 9' by 10' at seven years. The central reason for introduction was to have a true southern provenance that would perform well. I can attest to the disappointing *V. dentatum* cultivar performance in our UGA trials. Of the current five, none have any (much less reliable) fall color. All flower and fruit quite well, probably because of proximity of other pollinators.
- Papoose™ ('Papzam')—New pink-tinged leaves that have some gloss in summer and turn gold-red in fall, white flowers, and blue fruits on a compact, 5' high shrub. It is tighter and more densely branched than average *V. dentatum*. Introduced by Lake County Nursery, Lake Erie Series™.
- Pathfinder™ ('Patzam')—Glossy black-green leaves that are smaller and more deeply serrated than the species, white flowers, and metallic blue-black fruits. Grows 5 to 6' by 3 to 4' with a slender, upright habit. A Lake County Nursery introduction, Lake Erie Series™.
- 'Perle Bleu'—Described as producing heavy crops of blue fruits. It has medium green leaves and was in full, stinky flower on May 4, 2006 at the JC Raulston Arboretum. Grows 8 to 10' high, otherwise like the species.
- var. *pubescens* Ait.—Hairy in all its parts, hence its common name, downy viburnum. It is recognized for densely downy pubescent stems and leaf undersides with leaves of thicker texture; merged into *V. dentatum* by GRIN.
- Raspberry Tart™ ('Rastzam')—A true compact rounded form, 4 to 5' high and wide, with shiny green leaves that change to raspberry-red in fall. White flowers are followed by blue-black fruits. Another Lake County Nursery introduction, Lake Erie Series™.
- Red Feather® ('J. N. Select')—Leaves emerge red-purple, mature lustrous dark green, and then turn a consistent deep red burgundy in fall. Grew 6' by 5' in nine years. Mature size listed as 8 to 10' high and wide. Selected by Michael Yanny in 1989 from open-pollinated seedlings. Introduced by Johnson's Nursery, Menomonee Falls, Wisconsin.
- Red Regal™ ('KLMseven')—Reddish orange fall color and is upright, 8 to 12' high and wide. Zone 4 hardiness. A Roy Klehm, Beaver Creek Nursery introduction.

var. *scabrellum* Torr. & A. Gray.—The same as *V. ashei* Bush which is consistently the last viburnum to flower in the UGA trials. Foliage is smaller, lustrous, heat tolerant, and turns yellow in fall. White flowers with no noticeable odor arrive in late May—early June (June 12, 2006, Athens, Georgia) followed by blue fruits. Growth habit appears restrained. Probably maturing in the 5 to 8' range. There was a 7' by 10' dense, sprawling form with lustrous dark green leaves and scabrous stems at Hillier on July 1, 1999. Appears self-fruiting, as no other viburnums were in flower. Found naturally in east Texas, Louisiana, eastward to Florida. In full flower June 18, 2004 at the JC Raulston Arboretum; June 17, 2003 at the University of Georgia.

'Tree Form'—Listed by Louisiana Nurseries with small tree-like habit and large white flowers, followed by showy blue-black fruits.

Vanilla Cupcakes™ ('Vacuzam')—Offers large olive-green leaves and golden fall foliage on an upright-rounded plant that matures 5 to 6' high and wide. Large vanilla-white flowers are followed by bright blue fruits. A Lake County Nursery introduction and the heaviest fruiting of the Lake Erie Series™.

PROPAGATION: Seed, 180 to 510 days at fluctuating temperatures of 68 to 86°F, followed by 15 to 60 days at 41 to 50°F. Softwood cuttings are easy to root, 1,000 to 8,000 ppm IBA have given good results.

ADDITIONAL NOTES: Indians used the strong shoots which developed from the roots for the shafts of their arrows; hence, the name Arrowwood.

NATIVE HABITAT: New Brunswick to Minnesota, south to Georgia, Introduced 1736.

RELATED SPECIES: There are a great number of closely related species that do not differ significantly at least from a landscape standpoint although there are those who will disagree with this contention. Godfrey (1988) calls *V. dentatum* a polymorphic species complex interpreted various ways by different authors. If the readers can envision this group as a north-south, east-west continuum showing slight differences in leaf characteristics, pubescence, habit and size but possessing similar creamy white flowers and blue to blue-black fruits then they have grasped the essence of a confusing group of species.

Viburnum bracteatum Rehd., (vī-bēr'num brak-tē-ā'tum), Bracted Viburnum, is a difficult

species to properly identify, even for the advanced gardener. Consider it a souped-up version (72 chromosomes, an octaploid) of *V. dentatum* with glossier, thicker-textured leaves. Otherwise I see little difference between the two species, and, within the complex *V. dentatum*, individual plants that resemble *V. bracteatum* do appear. I have grown a selection, 'Emerald Luster', for ten years in the UGA trials that is 10' by 8' in outline: a respectable haystack. This lone specimen is tightly branched and, in foliage, lustrous dark green. Over the years, I have observed a number of plants labeled as *V. bracteatum*, but I am never absolutely convinced. The basis for the epithet is the presence of distinct bracts that subtend the inflorescence. Leaves, 2 to 5" long, 1 1/2 to 3" wide, almost rounded at times, with 5 to 6 vein pairs, ending in coarse dentate teeth; turn yellow to bronze in fall. Leaves are pubescent on impressed veins below; petiole is about 1/2" long and pubescent. Leaves display remarkable heat tolerance and hold up better than those of most named *V. dentatum* cultivars in Athens. Flowers, white and malodorous, open in early to mid May (Athens), in 2 to 3"(5") wide, flat-topped cymes.

On 'Emerald Luster' the flowers are borne in profusion, producing a striking contrast to the glossy dark green foliage. Tolerates sun and shade (will be more open in shade) in well-drained soils. Excellent drought tolerance as evidenced by ten years in Georgia trials without flinching. Makes a great screen, shrub border, or naturalizing and wildlife shrub. Unique in that the purple-blue-black fruits (at least of 'Emerald Luster') occur in profusion without cross-pollination, meaning a single plant is self-fruitful. Easy to root from cuttings and to grow in containers. The species grows to 10' high and wide. A 15' tall plant of the species resides in the Hillier Arboretum. Zones 6 to 8. Native to the southeastern United States.

Viburnum bracteatum

Viburnum molle Michx., (vī-bēr'num mol'lē), Kentucky Viburnum, melds into the *V. dentatum* complex, and doubtfully, by leaf, could it be separated from the *V. dentatum* taxa. According to the molecular work of Winkworth and Donoghue, *Viburnum* phylogeny based on combined molecular data: implications for taxonomy and biogeography. *American J. Bot.* 92:653–666 (2005), it is more closely related to *V. ellipticum* from the West Coast than *V. dentatum*. The dark green leaves, 2 to 5 inches long and about as wide, 8 to 10 vein pairs, coarsely dentate, are soft pubescent on the lower surface (sometimes with reddish glandular hairs). The 1/2 to 2" long, slender petioles are glabrous to glandular-hairy. Flowers, white, in 5- to 7-rayed, 2 to 3 1/2" wide cymes in May are followed in August–October by 3/8" long, ellipsoidal, bluish black fruits. The species forms a rounded shrub, 8 to 12' high and wide, and resembles everyday

V. dentatum. The major difference is the gray to brown exfoliating bark, which shreds in papery pieces not unlike *Acer griseum*, paperbark maple. Excellent naturalizing plant but seldom available in commerce. Grows in calcareous (limestone) soils on rocky hills and bluffs. Zones (5)6 to 8. Native to Pennsylvania to Arkansas and Missouri. Introduced 1923. ***Viburnum ozarkense*** Ashe is related and was recently elevated to legitimate species status based on field work and morphological analysis. Now considered an endemic shrub species of the Interior Highlands of Arkansas, Missouri, and Oklahoma. Not listed in GRIN.

Viburnum rafinesquianum Schultes, (spelled *V. rafinesqueanum* in GRIN), (vī-bēr'num raf-in-es-kwē-ā'num), Rafinesque Viburnum, Downy Arrowwood Viburnum. I knew little about this native, relatively compact, finely twiggy species that inhabits Canada (Quebec and Manitoba) and much of the eastern United States (to Arkansas, Missouri, and Kentucky). I observed thriving specimens at the Minnesota Landscape Arboretum (Zone 4) and the UGA Botanical Garden (Zone 7). These specimens were compact, 5 to 6' high, 6 to 8' wide, and densely clothed with 1 to 2 1/2" long, 1 to 1 3/4" wide, dark green, 4- to 6-veined, coarsely toothed leaves. I noticed mildew on a plant at the Minnesota Landscape Arboretum on July 20, 2005. Leaves emerge early, generally mid to late April in the Chapel Hill, North Carolina, area, where the species is abundant in the understory. Fall color is muted red to russet-red, and I continue to look for a bright red fall-coloring seedling. The white, malodorous flowers are held in 1 1/2 to 3" wide, 5- to 7-rayed terminal cymes in late April–early May (Chapel Hill). Flower abundance is prominent in shade, even more so in sun. Fruits are black, not particularly showy, 1/3" long, ellipsoidal, lost among the foliage, ripening by July. Have observed some fruits transitioning from red to black. Adaptable to extremes of soil and climate, full sun and shade, and tolerant of heat and drought. In 2005, extreme drought conditions prevailed from early July to early October in Chapel Hill. Although showing some effects of stress, I did not see a brown (dead) plant among the extensive native populations. Many years past, Mark Griffith, a former student, propagated liners and offered same through Griffith Propagation Nursery. I think Mark still has some for sale . . . A utilitarian plant for native landscapes. Beautiful in woodland settings. Usually found in calcareous soils of dry slopes and woods. Zones (3)4 to 7.

Viburnum rafinesquianum

CULTIVARS:

'Louise's Sunbeam'—A yellow-foliage shrub, discovered in North Carolina by the author in May 2005. Compact, dense, 4' high and wide, it is named after Louise Quinlan, our youngest daughter's, Susy's, organ donor. The noble and memorable story of its discovery brings me to tears. In mid April 2006, I returned to the original location and walked the site, discovering two additional yellow-leaf seedlings. I suspect that seeds from the original plant gave rise to these color variants. All are safely ensconced in an undisclosed location as I evaluate the three for potential release into commerce. Our goal is to give any royalties to the Sweet Melissa Fund at the University of North Carolina, Chapel Hill, which supports lung transplant patients and their families.

Viburnum recognitum Fern. (*V. dentatum* var. *lucidum* Ait. by GRIN), (vī-bēr'num re-kog-nī'tum). Tangentially a subset of *V. dentatum* but given species status, *V. recognitum* is a large shrub, listed as 10 to 15' high and almost as wide, but my sightings of cultivated plants reflect 5 to 6' by 5 to 8', and 8' high and wide. Further field notes state, "Much like *V. dentatum* in habit, leaf, and flower" (July 1, 1999 at Hillier). Hillier plant was broad-rounded, extremely dense, 10' by 12', with lustrous dark green foliage. The typical thinnish, lighter green leaves are 2 to 4" long and as wide or wider, with 10 to 15 pairs of coarse marginal teeth and 6 to 8 vein pairs. Leaves on the herbarium specimens varied from ovate to rounded, typically longer than wide. The leaf underside and petiole are prominently pubescent; likewise the buds and stems. Bean, W.J. *Trees and Shrubs Hardy in the British Isles*. Vol. 4. St. Martin's Press, New York (1981), stated that the parts are essentially glabrous. The flowers, white, open in June in 3 to 5" wide cymes. Blue-black, 1/3" long, oval-round fruits mature in late

Viburnum recognitum

summer. Like *V. dentatum*, very adaptable but better suited to cold-climate areas. Zones 4 to 6. From a landscape viewpoint, not sufficiently distinct from the better adapted and superior *V. dentatum* cultivars. Native to eastern North America. Typically more northerly distribution than *V. dentatum*. Introduced in the 18th century.

Viburnum dilatatum Thunb. — Linden Viburnum

(vī-bēr'num dī-la-tā'tum)

LEAVES: Opposite, simple, suborbicular to broad-ovate to obovate, 2 to 5" long, to about one-half to three-quarter's as wide, abruptly short acuminate, rounded or subcordate at base, coarsely toothed, dark green above, often lustrous, hairy on both sides, with 5 to 8 pairs of veins; petiole—1/4 to 3/4" long.

BUDS: Imbricate, slightly pubescent, 4 to 6 bud scales, blunt, brownish, often with a tinge of red in the scales.

STEM: Young branches hispid, brown, lenticels-orange (prominent).

SIZE: 8 to 10' in height, 2/3's to equal that in spread, actually have observed a few plants wider than tall.

HARDINESS: Zone (4)5 to 7, possibly in Zone 8 where some shade is helpful but does not appear well adapted, have seen in Zone 9 but the plants were languishing, seriously injured along with 'Catskill' and 'Erie' at Orono, ME.

HABIT: Often upright, somewhat leggy and open; also dense and compact in other forms; selection is the key within this species; the cultivars are superior to run-of-the-mill seedlings.

RATE: Slow-medium.

TEXTURE: Medium in leaf, medium to coarse in winter.

LEAF COLOR: Dark green, often lustrous, changing to an inconsistent russet-red in fall, may range from bronze to burgundy, leaves hold late.

FLOWERS: White, 1/4" diameter, May to early June, effective 7 to 10 days, borne in pubescent (pilose), flat-topped, 3 to 5" diameter, mostly 5-rayed cymes; often profusely produced and literally smothering the plant in a veil of creamy white, malodorous, significantly so; flowers mid May, Athens.

FRUIT: Drupe, 1/3" long, ovoid, bright red, cherry red or scarlet (excellent color), September to October and often persisting into December (sometimes into spring) when fruits may take on the appearance of withered red raisins; I have seen fruiting cymes heavy enough to bend the branches; plant several clones for best fruiting; superior selections are available that hold their fruit color through winter; Don Shadow, Winchester, TN has a fine, somewhat upright selection ('Asian Beauty') that maintains the glossy rich red fruit color through winter while one of the outstanding U.S. National Arboretum selections, 'Erie', loses its rich red fruit color; I have compared these two forms as they grew side-by-side in the nursery in late January and the differences were quite striking.

CULTURE: Easily transplanted; best in slightly acid, even-moistured soils but will do well in higher pH situations; full sun or partial shade; seems to prefer cooler climates but can be grown in Zone (7)8 if sited properly; ideally in Zone 8 provide moist soil and partial shade.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Specimen, shrub border, all purpose shrub, ornamentally valuable in three seasons; outstanding for fruits, however, little used compared to the normal garden variety (forsythia, deutzia) shrubs; some of the new selections are outstanding and should be used in preference to seed-grown materials. Observed stray seedlings (red- and yellow-fruited) at Bailey Arboretum, Long Island, in 2007. Did not realize that the species would escape to any degree.

CULTIVARS: Many, with the best resulting from Egolf's breeding work and several other worthy introductions from plantspeople who kept their eyes open.

'Asian Beauty'—Shiny dark green foliage, russet-red fall color, and excellent cherry-red fruit production and color retention. Fruits persist with good color into winter, eventually darkening. 'Asian Beauty' has an upright habit with significant vigor, reaching 10' or greater with age. One of the best fruit producers, it is becoming more common in commerce. A Don Shadow introduction, Winchester, Tennessee.

'C. A. Hildebrant's' (PP 16,889)—Observed only once by the author and immediately identified as a selection of *V. dilatatum*. A recent sighting in a nursery catalog lists it as a *V. wrightii* selection. Supposedly grows only 4' and has great quantities of bright red fruits. The plants I witnessed were relatively compact, but I have doubts about the 4' size at maturity. Probably larger. The leaves are extremely lustrous dark green and perhaps more leathery than the run-of-the mill seedling. Also, the stems and leaf undersides as well as the petioles are covered with dense pubescence. This characteristic is common to *V. dilatatum*, whereas *V. wrightii* is essentially glabrous. A Conard-Pyle introduction.

Cardinal Candy™ ('Henneke') (PP 12,870)—Glossy foliage and good vigor. There were stinky white flowers fully open on May 10, 2006 at the JC Raulston Arboretum, Raleigh, North Carolina. Glossy red fruits are persistent, remaining into spring. Fruiting appears heavy without a pollinator. Listed as 5 to 6' high; I suspect larger based on the vigor of container plants at the Center for Applied Nursery Research, Dearing, Georgia. Zones (4)5 to 7. A Proven Winners® introduction selected by Rodney Henneke from a batch of seed-grown plants after -30°F killed all except for Cardinal Candy™.

'Catskill'—A dwarf *V. dilatatum* seedling selection made in 1958 from plants raised from seed obtained from Japan. 'Catskill' was selected for the compact growth habit; smaller and rounder leaves; and good autumn coloration. The compact, wide spreading growth habit has been constant. The smaller, dull, dark green leaves, which are more nearly rounded than on most *V. dilatatum* plants, assume good yellow, orange, and red fall coloration. The creamy white inflorescences are produced in May (late April 1994, Athens). The dark red fruit clusters, which are dispersed over the plant, ripen in mid August and provide a display until mid winter. There was an extremely dense 3 1/2' high and wide plant at Hillier in 1999. The original plant, at 13 years old, was 5' high and 8' wide. This selection did not do well in the Illinois field tests; however, it has performed well in Tennessee. A planting in the UGA Botanical Garden was 6' high, densely broad-rounded, and produced red fruits, although never as abundantly as its neighbor 'Erie'. See Egolf, Donald R. Eight new *Viburnum* cultivars (Caprifoliaceae). *Baileya* 14:106–122 (1966).

'Catskill'

'Erie'—Forms a rounded-mounded shrub, 6' high and 10' wide in 14 years. Dark green leaves assume good yellow, orange, and red fall color. Produces white flowers in 4 to 6" wide, flat-topped cymes and prolific red fruits, which after frost become coral and persist as coral to pink. Highly resistant to diseases and insects. Excellent performer in Cincinnati and Athens. In my experience, grows more upright than description just given; in Athens, it is now 10' by 8'. Excellent fruit set in Zone 7 if a cross-pollinator is available. Resulted from open-pollinated seed collected in Japan. Released in 1970. Styer Award recipient in 1992. See *HortScience* 10:430–431 (1957) and Egolf, Donald R. *Viburnum dilatatum* Thunb. cv. 'Erie' (Caprifoliaceae). N.A. 32226, P.I. 347259. *Baileya* 18:23–25 (1971).

'Iroquois'—Resulted from a cross of two *V. dilatatum* selections made in 1953. The cultivar was selected for large, thick-textured, dark green leaves; abundant inflorescences of creamy white flowers; large, glossy, dark scarlet fruits; and dense, globose growth habit. The heavy-textured foliage is ornamental in all seasons, glossy green in summer, and orange-red to maroon in autumn. In mid May the inflorescences transform the plant into a mound of creamy white. The glossy red fruits are larger than those on *V. dilatatum* plants. The flat, wide-spreading fruit clusters contrast well with the dark green leaves. The fruits, which ripen in late August, persist after the leaves have fallen, and often the dried fruits are in abundance in mid winter if not eaten by birds earlier. The original specimen was 9' high and 12 1/2' wide. Excellent form based on my observations; have seen fruit so heavy it weighs the branches down.

This is still one of the best forms and when well fruited is the envy of all the fruiting shrubs. See *Baileya* 14:109–112 (1966).

Littleleaf Form—A name I attached to a dark green, small-leaf taxon (about one-third to one-half the size of species' leaf) that Rick Crowder, Hawksridge Nursery, Hickory, North Carolina, showed me. I asked Rick about specifics, and he had no background information. Good-looking plant if it flowers and fruits like the species.

'Michael Dodge'—An introduction with all the fine qualities of the species except the large fruits are a beautiful bright yellow that is much more attractive than those of 'Xanthocarpum'. Fall color is reddish. Named after the White Flower Farm horticulturist, discovered by Hal Bruce at Winterthur, in Delaware. Supposedly matures smaller than most *V. dilatatum* types at 5' by 6'. This plant has a unique history as recounted in a January 24, 2001 letter from its namesake. In 1969, at Winterthur, Michael crossed 'Xanthocarpum' with *V. dilatatum*, and harvested, cleaned, and sowed fruits that same fall. They germinated in great abundance in the spring of 1970, but Michael then accepted a position at White Flower Farm. Hal Bruce lined out seedlings at Winterthur, and told Michael there were several attractive selections. Conard-Pyle, West Grove, Pennsylvania, was given propagation rights. I witnessed it in glorious fruit at Swarthmore College in fall 2001. Truly the best of the yellow-fruited *V. dilatatum* types and performing admirably in our UGA trials.

'Mt. Airy'—I discovered as a stray, misnamed seedling with lustrous leathery dark green foliage and abundant large bright red fruits while surveying the *Viburnum* collection at Mt. Airy Arboretum, Cincinnati, Ohio. Interestingly, about 30 feet away were plants of 'Erie' that were not close in fruit size and abundance; obviously ample opportunities existed for cross-pollination, so if good fruit were to occur, it should have. The new clone was 6 to 7' high and wide (10' high in 2004) with pleasing upright rounded outline. Cuttings were rooted, and the plant has found a small niche in commerce. Appears to be nothing more than a bird-planted seedling but has all the characteristics of true *V. dilatatum*. Early leafing by early April. Flowered mid April 1995 in the Dirr garden. Don Shadow tells me this cultivar is more cold hardy than most.

'Ogon'—A rare yellow-foliage form that was given to me by Ted Stephens, Nurseries Caroliniana, North Augusta, South Carolina. Unfortunately, in Athens, Georgia (Zone 7), it photobleaches (turns white) in full sun. In shade, it loses the color over time. Beautiful when first emerging, less so later.

'Oneida'—Resulted from a cross of *V. dilatatum* × *V. lobophyllum* made in 1953. This deciduous shrub was selected for the abundance of nonoffensive flowers in May (late April, Athens, Georgia; late May, Mt. Airy Arboretum, Cincinnati, Ohio) and sporadic flowers throughout the summer; its thin-textured foliage that turns pale yellow and orange-red in autumn; and its upright growth habit with wide-spreading branches. Because of the two or three sporadic flowering periods, abundant fruits are produced that ripen in August and persist on the plant until mid winter. The original plant has grown to a height of 10' and a width of 9 1/2'. It has not proven as impressive as 'Erie' and 'Iroquois' but is still a good choice. My more recent field notes are more positive, including comments about a 10' high plant with excellent red fruits on September 27 at Brooklyn Botanic Garden and a Swarthmore plant with fruits as good as any typical *V. dilatatum*. Also, the leaves and stems are more glabrous than typical *V. dilatatum* due to *V. lobophyllum* parent. See *Baileya* 14:106–122 (1966).

forma pilosulum Nakai—Pilose pubescence sticks straight out from stems and leaves. I have only observed this form once. Arguable whether it deserves taxonomic rank.

'Vernon Morris' (PP 17,936)—Cream-white to yellow-colored fruits on a large upright shrub. Introduced in 1993. Witnessed in brilliant yellow fruit in October on Long Island. Similar to 'Michael Dodge' in fruit.

'Xanthocarpum' (f. *xanthocarpum* Rehd.)—Has yellow to almost amber-yellow fruits, which are not produced in great abundance and do not make the show of the better yellow-fruited types. As I have seen the fruits, scarcely yellow in the classical sense, more yellow-orange. A rounded, dense, 6' by 8' form was recorded at Hillier on July 1, 1999. A plant grew in the great *Viburnum* collection at the Arnold Arboretum.

PROPAGATION: Seeds require about 5 months warm/3 months cold but even then germination is not guaranteed; softwood cuttings, 8,000 ppm IBA, peat:perlite, mist equals high rooting; I have rooted this species without difficulty; on July 24 collected cuttings of 'Erie' and 'Mt. Airy' in Cincinnati, OH, 10,000 ppm KIBA, 2 perlite:1 peat with 100 and 80% rooting, respectively, and 100% overwinter survival.

NATIVE HABITAT: Eastern Asia. Introduced before 1845.

RELATED SPECIES: A number of comparable species have been observed by the author. Doubtfully, will any supersede *V. dilatatum* in every day commerce, and it is not as easily obtainable as should be the case. *Viburnum betulifolium* Batal. with abundant red fruits at Trewithen Garden; *V. burejaeticum* Reg. & Herd. with heavy red fruits, eventually black, at the Morton Arboretum; *V. corylifolium* Hook. f. & Thorn.; *V. cotinifolium* D. Don.; *V. erosum* Thunb.; *V. hupehense* Rehd.; *V. ichangense* (Hemsl.) Rehd.; *V. kansuense* Batal.; *V. lobophyllum* Gräbn.; *V. phlebotrichum* Sieb. & Zucc. and possibly others might be considered. For substantial discussions of the above species, consult *Viburnums* (2007) Timber Press.

***Viburnum wrightii* Miq.** — Wright Viburnum
(vī-bēr'num rīt'ē-ī)

LEAVES: Opposite, simple, ovate or broad-ovate, 3 to 5" long, 1 to 2 1/2" wide, abruptly acuminate, rounded or broad-cuneate at base, coarsely dentate, dark green and glabrous above, essentially glabrous beneath, except tufts of hairs in axils of veins, 6 to 10 vein pairs; petiole—1/4 to 3/4" long.

STEM: Essentially glabrous which permits easy separation from *V. dilatatum*.

Viburnum wrightii, Wright Viburnum, is similar to the above but differs in its larger leaves and the relative absence of pubescence on the stem and inflorescence. I have seen true *V. wrightii* enough times to be able to separate it from *V. dilatatum*. The habit is upright-rounded, 6 to 10' high. The round-ovoid red fruits average about 1/3" in length and are quite showy. The dark metallic green leaves may turn a good red in fall. Might add that what is sold or labeled as *V. wrightii* in most situations is *V. dilatatum*. Native to Japan. Introduced 1892. Zone 5 to 7. Possibly, slightly more cold hardy than *V. dilatatum*.

CULTIVARS:

'Hessei' (var. *hessei* (Koehne) Rehd.)—A compact form with attractive dark green summer and red fall foliage and sealing-wax red fruits. Flowers, white, are produced in 2" wide cymes. In full flower April 26, 1999 at Hillier and my field notes state, "Actually fragrant." Apparently many plants were grown from seed collected by C. S. Sargent, Arnold Arboretum, by Hesse Nurseries, Germany. 'Hessei' has occasionally been listed as superior, but one person's 'Hessei' may not be the same as another's. 'Hessei' was 7' by 8', dense, with clean foliage and a heavy fruit set on June 30, 1999 at Hillier. Appears to have less pubescence than the species. Japan and Korea. Introduced 1909.

***Viburnum farreri* Stearn.** — Fragrant Viburnum
(vī-bēr'num fār'er-ī)

LEAVES: Opposite, simple, obovate or oval, 1 1/2 to 4" long, 1 to 2 3/4" wide, acute, broad-cuneate or cuneate, serrate with triangular teeth, sparingly pubescent above and pubescent on veins beneath, finally glabrous or nearly so, with 5 to 6 pairs of veins and the veinlets impressed above and below, dark green; petiole—1/3 to 3/4" long, purplish.

Viburnum farreri (*V. fragrans*) grows 8 to 12' tall with a similar spread and is often rather loose, unkempt and unruly. The foliage emerges bronzy-green and matures to dark green in summer changing to reddish purple in fall. The fragrant flowers are pinkish red in bud opening to white tinged with pink, early to mid-April before the leaves, borne in a 1 to 2" long and wide panicle; one of the earliest viburnums to flower. Fruit colors red, finally black and is effective in July to August but I have never seen a good display. The flowers often open in the fall on a rather sporadic basis and push forth full force in spring at the first sign of warm weather. Unfortunately, late frosts wreak havoc on the species and it is seldom that the flowers are not browned to one degree or another. I grew the species in my Illinois garden and enjoyed the foliage more than the flowers which suffered from the vagaries of the midwestern winters. I have had good success rooting the species and 'Candidissimum' from softwood cuttings. Northern China. Introduced 1910. Zone (4)5 to 8. Has survived and performed reasonably well at the Morton Arboretum, Lisle, IL.

CULTIVARS:

- 'Bowles' ('Bowles' Variety')—Listed by the University of British Columbia Botanical Garden, is described as superior to the species. Considered lost to cultivation by Kenyon (2001).
- 'Candidissimum' ('Album')—Produces pure white fragrant flowers that are more easily singed by cold. Fruits are described as light yellow but I have yet to see. The leaves show no reddish pigmentation in spring or fall. Their summer color is a soft yellow-green. Typically not as vigorous or large as the species although a 10' high specimen grew at RHS Hyde Hall. A 6' by 4' upright plant is at Hillier.
- 'Farrer's Pink'—Pink flowers. There was a 10' tall plant at RHS Hyde Hall and a 6' by 3' foot young plant at Hillier in 1999.
- 'Fioretta'—A stocky, compact form with pink flowers from November to March; reported to grow 5' high in ten years (Houtman, Ronald. 1998. *Viburnum. Dendroflora* 35:96–148).
- Fragrant Breeze™ ('KlmV')—Exceptionally fragrant soft pink flowers, freely produced before the leaves; upright in youth, spreading with age; good cut-branch form; 8 to 12' by 8 to 10' in 10 years; Roy Klehm introduction.
- 'Mount Joni'—An early-flowering form that repeats in spring.
- 'Nanum'—Can either delight or shock, depending on condition. Small, to 5', usually less, rounded becoming lumpy with age, it produces small panicles of pink flowers in spring. A dense, compact plant, 3 1/2' high and wide, grew at Hillier in 1999. Foliage is similar to the species but smaller. Leaves 1 1/2 to 2 1/2" long, 3/4 to 1 1/4" wide, petiole 1/2 to 3/4" long, shorter intervals between nodes, 1/2 to 1" apart. Overall shrub appears bronze-green. If groomed properly, a respectable garden addition.
- White Perfume™ ('KlmW')—Early, strongly fragrant, freely produced, tight inflorescences of small, white flowers; 8 to 12' by 8 to 10' in 10 years; Roy Klehm introduction.

RELATED SPECIES:

Viburnum ×bodnantense Stearn., (vī-bēr'num bod-nan-tens'ē), Bodnant *Viburnum*. My affection for this group of hybrids between *V. farreri* and *V. grandiflorum*, named after Bodnant Garden in Wales where they originated, ebbs and flows with the seasons. From fall to spring, fragrant flowers are often present. The floral effect is not overwhelming, but the fragrance and unique timing more than compensate. I grew *V. farreri* in our Urbana, Illinois, garden, where it prospered; *V. ×bodnantense* in Georgia, where it perished. This was my fault for I sited it in full sun and a dryish location. 'Dawn', in other southern gardens, properly sited, has performed with dignity. The foliage is akin to *V. farreri*, 2 to 4" long, 1 to 2" wide, bronze when emerging, later medium green, narrowly oval, tapering at the ends and regularly toothed except at the base. Described in European literature as having good autumn color, this has not occurred under my watch in the United States. The fragrant flowers appear from the naked branches in cymes that are 1 to 2" wide by approximately 1" high. The buds are pink (varying degrees) and open to lighter colors (pink to almost white). The red fruits mature in summer (June in England) and in my experience are limitedly produced. They eventually turn black at maturity, but I have yet to witness this latter color stage. The habit is cumbersome and stiff, upright in youth, eventually somewhat rounded. Certainly more appealing when fully foliated than naked-stemmed. Will grow from 8 to 10'(15') high and wide, or wider. Behemoth-like specimens are common in English gardens. Quite adaptable, sun and shade, with reasonable moisture. Grows from Chicago, Illinois, to Atlanta, Georgia. Zones 5 to 7, 8 and 9 on West Coast.

CULTIVARS: The three cultivars—'Charles Lamont', 'Dawn', and 'Deben'—have separate origins. The original crosses were made by Charles Lamont in 1933 at the Royal Botanic Garden, Edinburgh, using *V. grandiflorum* as the maternal parent. Initially, none were considered worthy of naming. Flowers open over an extended period, so if injured by cold, another spurt follows. There is a surreal, mystical aura to the flowers, and as I traipsed around the Hillier Arboretum in February and March in the dank and cold, I had the "feeling" that I was being watched. Can plants see? Certainly worthwhile plants for the winter garden. Their oafishness can be masked by groundcover shrubs and perennials like *Sarcococca*, *Danae*, *Helleborus*, and *Skimmia*.

'Charles Lamont'—A seedling with brighter pink flowers (than 'Dawn') and a more free-flowering nature. Leaves are the largest of the three cultivars (the *V. grandiflorum* trait). An upright-spreading, stiff, coarse plant, 15' high and 10' wide, grew at Hillier in 1999. A 15 to 18' high specimen grew at RHS Wisley on May 25, 2006.

'Dawn'—Derived from *V. farreri* × *V. grandiflorum* (1934) by Charles Puddle, head gardener at Bodnant Garden, Wales. The flowers are pink with dark purple-pink anthers. This is the most common form in cultivation in the United States. Witnessed a 12' by 8' plant with great foliage at Hillier on July 2, 1999.

'Deben'—Appeared as a chance seedling at Notcutts Ltd., England. The buds are pink, opening apple-blossom pink, and fading to white. Flower clusters are larger than those of 'Dawn'. May be a cross with *V. farreri* 'Candidissimum' as one parent. The flowers show cold injury (browning) more so than 'Dawn' and 'Charles Lamont'. There was an upright-spreading form, 12' high by 10' wide, at Hillier in 1999.

Viburnum japonicum (Thunb.) Spreng. — Japanese Viburnum
(vī-bēr'num ja-pon'i-kum)

LEAVES: Opposite, simple, evergreen, leathery, ovate to broad-ovate, 3 to 6" long, 2 to 4" wide, abruptly acuminate, cuneate to rounded, nearly entire with remote teeth toward apex, leathery lustrous dark green and glabrous above, lighter green and glabrous below with minute black dots, 3 to 5 vein pairs, veins impressed; petiole—1/2 to 3/4" long, reddish green, channeled above; leaves with no distinct odor when crushed.

BUDS: Terminal—loosely scaled, reddish green, glabrous, 1/2" long; laterals—with 3 visible scales, appressed, 1/4 to 1/3" long.

STEM: Stout, angled, green initially, finally gray, with onion skin type of epidermis, remote small rounded orangish brown lenticels; pith—white, solid, ample.

Viburnum japonicum is an evergreen shrub that matures between 6 to 8' in height and width. Have seen 10' high plants in England; Lancaster in *Viburnum conundrum*. *The Garden* 125:(11) 822–823 (2000) noted 20' high plants were recorded in Japan. It is extremely dense in habit and would make a fine screen. The lustrous dark green foliage is attractive throughout the seasons. The fragrant, white, 3/8" wide flowers are produced in 2 to 4" diameter, rounded, short-stalked, 7-rayed cymes. The fruit is a 1/3" long, oval-rounded, red drupe. Terribly confused with *V. awabuki* and *V. odoratissimum* which are more prevalent in U.S. cultivation than true *V. japonicum*. Observed plants in Raleigh and Atlanta with reasonable vigor. One of the parents of 'Chippewa', 'Huron' and 'Fugitive', providing the genes for superior lustrous, leathery, dark green foliage. Japan. Introduced 1859. Zone 7 to 9.

CULTIVARS: An arbitrary system since two of the clones, 'Huron' and 'Chippewa' have true *V. japonicum* as a common parent and are most logically included here. Have evaluated in Athens for five years. Seldom hear anything mentioned about the two cultivars even among the most ardent viburnum supporters. Reported that both 'Huron' and 'Chippewa' need to be in close proximity for good fruit set.

'Chippewa'—A hybrid between *V. japonicum* × *V. dilatatum* with semi-evergreen to deciduous leaves and a densely branched, multi-stemmed nature. The parent plant was 8' high and 10' wide after ten years. Leaves are glossy, leathery dark green, 2 to 4 1/2" long, 1 1/2 to 3" wide, and turn dark maroon to bright red in autumn. The white, malodorous flowers occur in 4 to 7 1/2" wide, 5- to 7-rayed cymes containing 200 to 300 flowers per inflorescence. Oblong dark red, 3/8" long, 1/3" wide fruits ripen in August and persist into winter. No winter damage has occurred at −10°F, but foliage is deciduous. A five-year-old plant is 6' high and 8' wide in the UGA trials. Generally, 'Chippewa' is more irregular and not as effective as the more compact 'Huron'. Flowers seven to ten days ahead of 'Huron'. Fruit set has been minimal. Remarkably good heat tolerance in Zone 7. The result of a backcross by Egolf utilizing embryo rescue to generate plants.

'Fugitive'—Could go with *V. dilatatum*, but better here; recently (mid May 2007) saw the plant at McCracken's Nursery and it is a *V. dilatatum* × *V. japonicum* hybrid; plant was about 6' by 6'; full and dense with cream-white flowers; do not know actual origin.

'Huron' (*V. lobophyllum* × *V. japonicum*)—A tardily deciduous (December, Zone 7), dense-branched, multi-stemmed shrub that grew 7 1/4' by 9 1/4' after 17 years. Leaves are leathery, dull dark green turning rich purple in late autumn. Holds leaves later than 'Chippewa'. White flowers occur in 4 to 6" wide, 6- to 7-rayed cymes containing 250 to 400 florets per inflorescence. Flower buds just showing on April 15, 2006 at the Sarah P. Duke Gardens, Durham, North Carolina; in full flower April 26, 2003 in Athens, Georgia. Ovoid dark red, 1/4 to 1/3" long, 1/3" wide fruits ripen in August and persist into winter. Hardy to at least −10°F, at which temperature it is deciduous. For additional information on both cultivars, see Egolf, Donald R. 'Chippewa' and 'Huron' viburnums.

Viburnum
'Huron'

HortScience 22:174–176 (1987). The plant in the Georgia trials is 4' high and wide after five years. Habit is more compact and dense than 'Chippewa'. Fruit set has not been heavy.

'Variegatum'—A marble-cake mix of cream and yellow on a bronze background as the leaves emerge, cream-yellow on glossy green with maturity. Slower growing than the species, and I have noticed reversions. A collector's plant. A 6' high plant grew in the JC Raulston Arboretum. This plant had two variegated shoots remaining when observed June 29, 2006; all others green.

RELATED SPECIES:

Viburnum awabuki K. Koch (*V. odoratissimum* var. *awabuki* (K. Koch) Zabel according to GRIN)
(vī-bēr'num a-wa-bū'kē)

LEAVES: Opposite, simple, evergreen, ovate-lanceolate, 3 to 6 1/2" long, 1 1/2 to 2 1/4" wide, obtuse to acute, cuneate, remotely serrate (quite variable), leathery lustrous waxy dark green and glabrous above, dull olive-green below and glabrous, 7 to 11 vein pairs; petiole—3/4 to 1" long, stout, brown and rubbery; leaf with no discernable odor when crushed.

BUDS: Terminal—large, 1/2" long, grayish brown, glabrous with long-pointed scales; laterals—smaller, otherwise similar.

STEM: Stout, angled, brown, glabrous, dotted with abundant grayish lenticels; pith—white, solid, ample.

Viburnum awabuki, a large lustrous dark green leaf form of great beauty, was promoted by the late J.C. Raulston. He mentioned observing "large pendulous masses (6 to 10" diameter) of bright red fruits hanging in the 15' tall plant like ornaments on a Christmas tree." There is a large 15 to 20' high specimen at the Augusta National Golf Course. I have a gift plant from Dr. Raulston that above 10°F showed no injury. Unfortunately, the nomenclature of this form is confusing, being a Japanese continuum of the widely distributed *V. odoratissimum*. *Hortus III* reduces it to var. *awabuki*. Perhaps the var. *awabuki* should be more properly classified under *V. odoratissimum*. *Viburnum awabuki* is also listed as *V. macrophyllum*, a name with no botanical credibility. It is often confused with *V. odoratissimum* but the young wood is not so warted, the secondary veins run to the margin, and the inflorescence is rounded-cymose rather than paniculate. 'Chindo' was introduced by J.C. Raulston, discovered in a schoolyard on Chindo Island, Korea, noted for producing large, pendulous, red fruit clusters, grows 15 to 20' high, from my perspective not much different than typical *V. awabuki*, probably requires cross pollination for heavy fruit set, protect from wind, cold, winter sun. 'Variegatum' has white margins and dark green centers. Prone to reversion but striking when stable. Japan. Introduced 1879. This is a handsome viburnum and probably best suited to Zone 7 and into 9. In the South, this has been grown and cultivated as *V. japonicum*, *V. macrophyllum*, and *V. odoratissimum*. Has become popular for grouping and screening. I see the species in significant usage in southeastern landscapes. Also, a more compact form that for 10 years in Georgia trials is only 8 to 10' high. Definitely different from the typical, rapid-growing species type.

Viburnum odoratissimum Ker.-Gawl.
(vī-bēr'num ō-do-ra-tis'i-mum)

LEAVES: Opposite, simple, evergreen, elliptic-ovate to elliptic-oval, 2 to 4" long, 1 to 2 1/4"(3") wide, obtuse, rounded, entire or with remote teeth toward apex, dull olive-green and glabrous above, pale gray-green below with 4 to 6 vein pairs, with brownish tufts of hair in the vein axils, veins not as impressed as *V. japonicum*; petiole—1/4" long, glabrous, brown; leaf when broken extremely fetid, similar to odor of *V. sieboldii* leaves.

BUDS: Laterals—valvate, with two loosely fitting scales, 1/3" long, brownish green, glabrous.

STEM: Stout, brown, glabrous, dotted with numerous, small grayish lenticels; pith—white, ample.

Viburnum odoratissimum has a dull dark green upper leaf surface, the leaf is wider, and with foul odor when broken. It grows 10 to 20'(30') high and is

relegated to Zone 7, ideally 8 to 10. 'Red Tip' with young foliage reddish green is known. Japan. 'Red Tip' and the species are less cold hardy than *V. awabuki*. Witnessed large screen, 20' high, at Louisiana Nurseries, Opelousas, LA and a 50' high tree at Leu Gardens, Orlando. Grows as an understory tree in broadleaved evergreen forests near the coast, even under gloomy (shady) environments. India, southeast Asia, Japan, Taiwan, Java, Philippines, and Celebes (Sulawesi).

Viburnum lantana L. — Wayfaringtree Viburnum

(vī-bēr'num lan-tā'na)

LEAVES: Opposite, simple, ovate to oblong-ovate, 2 to 5" long, 1 1/2 to 4" wide, acute or obtuse, cordate to rounded at base, rather closely denticulate, dark green and sparingly stellate-pubescent and wrinkled above, stellate-tomentose beneath; petiole—1/2 to 1 1/2" long; very uniform serrations and a strong reticulate venation pattern are good identification features.

BUDS: Naked, foliose, grayish tomentose; flower buds similar to *V. carlesii* but larger and coarser.

STEM: Young branches light gray-brown, scurfy pubescent, older branches gray, usually heavily lenticelled, stout, coarse, thick.

SIZE: 10 to 15' in height (possibly as large as 20') by 10 to 15' in spread.

HARDINESS: Zone (3)4 to 7(8), does not appear vigorous in Zone 7, in fact not well-suited in the mid and lower South.

HABIT: Multi-stemmed shrub with stout spreading branches, usually rounded in outline, often leggy.

RATE: Medium.

TEXTURE: Medium in leaf, often quite ragged in winter habit, appearing coarse.

LEAF COLOR: Dull dark green (almost a bluish green), leaves quite pubescent below and somewhat leathery in texture; fall color tends toward purplish red; however, very inconsistent in Midwest and East, often poor.

FLOWERS: White, no fragrance (somewhat stinky?), actually creamy due to numerous yellow stamens, early to mid-May, 10 to 14 days, borne in 3 to 5" diameter, flat-topped, 7-rayed cymes; flowers profusely in Midwest.

FRUIT: Drupe, 1/3" long, yellow changing to red and finally black, often all colors present in same infructescence, August to late September, outstanding attribute of this plant; I have noticed that fruit set is best when several different clones are in close proximity.

CULTURE: Fibrous rooted, readily transplanted; withstands calcareous and dry soils better than other viburnums; sun or 1/2 shade; prefers well-drained, loamy situation.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Used for hedges, screens, massing, shrub border; foliage persists until November in parts of Midwest; winter coarseness should be considered before this species is used extensively; reports of it escaping and seeding in woodlands in northern Illinois and I suspect other midwestern locales; lost some of its cachet with the advent of improved cultivars like 'Mohican' and 'Alleghany', *V. lantana* × *V. rhytidophyllum* hybrids.

CULTIVARS:

'Aureum'—Rather handsome golden yellow young shoots, later becoming green. I have seen this form on occasion, not too offensive. Reported to hold yellowish coloration when sited under some shade. Not as large as the species, to 8' high, and not as vigorous. Witnessed a 7' by 10' plant at Hillier in 1999. Leaf shape, size, and pubescence similar to the species. During a visit to England in late May 2006, I noted several plants with diminished yellow leaf color. Introduced in 1921 by Spaeth of Germany.

var. *discolor* Huter—Smaller, 1 3/4 to 2 1/2" long, 1 to 1 1/2" wide, serrated, firmer-textured leaves with dense woolly, almost white, pubescence below. Upper surface is lustrous dark green with short

pubescence. Eight to 10 vein pairs. Habit is more compact than the species. Has potential for breeding improved foliage characteristics into *V. lantana* and related taxa. Noted a loose, open habit on a 3 1/2 to 5' plant at Hillier on July 1, 1999.

'Emerald Triumph'—Bred by Harold Pellett, University of Minnesota, for its superior, lustrous dark blue-green foliage, red to black fruits, maroon fall color, and more compact habit. I have tracked the excellent performance of this hybrid from the Lyle E. Littlefield Ornamental Gardens at the University of Maine, Orono, to the JC Raulston Arboretum in Raleigh, North Carolina. In the author's opinion, it is superior to everyday *V. burejaeticum*, *V. lantana*, or *V. ×rhytidophylloides*. 'Emerald Triumph' is more compact than *V. burejaeticum*, probably 6 to 8' high and wide. Leathery lustrous dark green foliage. White flowers in 2 to 3" wide cymes and green-red-black, 3/8 to 5/8" long, ovoid fruits that mature earlier than *V. lantana*. Red coloration lasts for three to four weeks. An excellent viburnum for northern Zones 4 to 6(7). This form was about 50% leafed out on March 23, 2004 and in full flower April 6, 2004 at the JC Raulston Arboretum. Somewhat resistant to the viburnum beetle. Introduced in 1994 see Rose and Pellett, *J. Environ. Hort.* 12(1):59–60 (1994).

'Macrophyllum'—As I witnessed on April 14, 1999 at RHS Wisley, has larger leaves than the species, and the inflorescences are listed as much as 8" across.

'Mohican'—A seedling selected in 1956 from a population grown from *V. lantana* seed received from Poland. The plant, as a deciduous shrub, was selected for compact growth habit, thick dark green leaves, persistent orange-red fruits, and resistance to bacterial leaf spot. Leaves are 3 1/2 to 4 1/2" long, 1 3/4 to 2 1/4" wide, pubescent on both surfaces but not to the degree of typical *V. lantana*; in fact, the underside of the leaf is more green than the gray one would expect from *V. lantana*. The creamy white flowers and expanding pale green leaves appear together for a week in early May. The orange-red fruits begin to ripen in early July and remain effective for four or more weeks, whereas fruits on other *V. lantana* plants pass rapidly from red to black. The original specimen in 15 years had grown to 8 1/2' high and 9' wide. Witnessed a 10' by 8', oval-rounded, dense specimen with clean foliage and heavy fruit at Hillier on July 1, 1999. An Egolf introduction and now quite popular in the nursery trade.

'Rugosum' (var. *rugosum* Lange)—Leathery-leaf form with larger, darker green leaves that are more handsome than those of the species. Tends to become open and rather ragged with age.

'Variegatum'—Yellow-variegated leaves.

'Variifolium'—Spotted, speckled, and swooshed white, cream, and yellow variegation. New leaves emerge tinged pink-bronze. They average 3" by 2 to 2 1/2", appearing rounded. The variegation was stable and the plant more compact (5') than the species. Have observed this twice, and it appears unique from 'Variegatum' and 'Versicolor', although the latter name has been used as a synonym for 'Variifolium'.

'Versicolor'—Pale yellow young leaves, finally turning gold.

PROPAGATION: Cuttings, softwood, root easily. This species is often grown from seed.

NATIVE HABITAT: Europe, western Asia, occasionally escaped from cultivation in eastern United States. Long cultivated.

Viburnum lantanoides Michx. — Hobblebush (formerly *V. alnifolium* Marsh.)

(vī-bēr'num lan-tā-noi'dēz)

LEAVES: Opposite, simple, broad-ovate to suborbicular, 4 to 8" long, nearly as wide, short acuminate, cordate, irregularly denticulate, stellate-pubescent above at first, later glabrous and dark green, more densely pubescent beneath, chiefly on the veins; petiole—1 to 2 1/2" long, scurfy.

Viburnum lantanoides is a straggling shrub with pendulous outer branches; often develops a procumbent habit and roots develop where the branches touch the ground; reaches 9 to 12' in height. The summer foliage is medium to dark green and develops reddish to deep claret in fall although I saw plants in Maine in rather deep shade that were beautiful rose-gold, green-gold to pinkish purple. Color or semblance of same develops early and it is not unusual to experience blushed red to red-purple leaves in mid to late summer. Easy plant to identify because of the large leaves, premature fall coloration and somewhat straggly habit. In the southern Appalachians, the plant grows in identifiable quantities above 3,000' elevation. One of my favorite discoveries when hiking. The flowers are borne in flat-topped, 3 to 5" diameter cymes, the outer flowers of which are sterile, white, about 1" diameter and produced in mid-May. The fruit is a red, finally purple-black drupe about 1/3" long which matures in September. Probably

requires two seedlings to facilitate cross-pollination and heavy fruit set. This species is maximally adapted to shady, moist areas. This is a shrub that one has to adapt to for it lacks the symmetry of many viburnums. Probably best adapted to a naturalized situation. 'Praecox' is described as flowering three weeks before the typical species. I have yet to see this form. 'Serenity' was listed by Eastern Plant Specialties, Georgetown, ME, for more restrained habit. Native to New Brunswick and Michigan to North Carolina in the mountains. Introduced 1820. Zone 3 to 5(6).

Viburnum lentago L. — Nannyberry Viburnum, Sheepberry

(vī-bēr'num len-tā'gō)

LEAVES: Opposite, simple, ovate to elliptic-obovate, 2 to 4" long, half as wide, acuminate, broad cuneate to rounded at base, finely toothed, lustrous dark green and glabrous above, glabrous or scurfy on the veins beneath; petiole—1/2 to 1" long, mostly winged with wavy margin.

BUDS: Vegetative—valvate in nature, long pointed, slightly curved, lead-gray in color, 3/4 to 1" long; flower buds—fat at base and tapering to a long point, about 1" long.

STEM: Slightly pubescent to essentially glabrous, brownish in color.

SIZE: 15 to 18' possibly to 30' in height, spread quite variable, national champion is 22' by 14' in Ontonagon County, MI.

HARDINESS: Zone 3 to 7, seldom grown in Zone 7.

HABIT: Shrub or small tree with slender finally arching branches, somewhat open at maturity, often suckering.

RATE: Medium.

TEXTURE: Medium in leaf, medium-coarse in winter.

LEAF COLOR: Soft yellow-green when unfolding, gradually changing to glossy dark green; fall color develops purplish red but is not guaranteed, often poor green and falls off as such.

BARK: Blackish, patterned scaly to blocky.

FLOWERS: White, appearing creamy due to yellow stamens, early to mid-May, 7 to 10 days, borne in 3 to 4 1/2" diameter, flat-topped cymes; flower is good but color is typical of many viburnums.

FRUIT: Drupe, oval, 1/2" long, bluish black, bloomy, September to October and often December; common name is derived from smell of the fruits; the color actually starts out green and in the course of maturation may show tinges of yellow, rose and pink before finally becoming bluish black; actually most handsome in the early stages of coloring.

CULTURE: Fibrous rooted, transplants readily, often suckers profusely forming a thicket; adaptable to a wide range of conditions; sun or shade; native species of great durability; moist or dry soils.

DISEASES AND INSECTS: Mildew may occur, especially when grown in shaded area; usually no serious problems are encountered.

LANDSCAPE VALUE: Ideal shrub for naturalizing, works well in shrub borders, as a background or screen plant and limitedly for specimen use; good winter food for the birds; large notable specimen at Biltmore Gardens, almost tree-like, 25' high, flowers late April—early May.

CULTIVARS:

'Deep Green'—Thick glossy leaves, white flowers, and pink-rose to black fruits grows to 20' high. Listed by Fairweather Gardens, New Jersey.

'Pink Beauty'—Has pink fruits maturing to violet; I have never seen the cultivar but Krüssmann mentions that it is quite attractive.

'Show Girl' (variegated) and 'Nanum' are also in the literature but doubtfully available.

PROPAGATION: Seed, 150 to 270 days at 68 to 86°F fluctuating temperatures followed by 60 to 120 days at 41°F. Cuttings, softwood; from personal experience this species roots easily from softwood cuttings.

ADDITIONAL NOTES: A hybrid, *Viburnum xjackii* Rehd., between *V. lentago* and *V. prunifolium* exists. If the identification characteristics do not fit one or the other species, blame it on hybridity.

NATIVE HABITAT: Hudson Bay to Manitoba, south to Georgia and Mississippi. Introduced 1761.

Viburnum obovatum Walt. — Small Viburnum

(vī-bēr'num ob-ō-vā'tum)

LEAVES: Opposite, simple, evergreen, semi-evergreen to deciduous, oblanceolate to spatulate, some rounded-obovate, 3/4 to 2" long, 1/3 to 1 1/4" wide, obtuse or rounded, cuneate, entire or finely serrate midway to apex, dark green, often lustrous, glabrous, lower surface brown dotted; sessile or with petiole to 1/5" long, red.

BUDS: Extremely small, 1/32 to 1/16" long, rusty brown, pubescent, not unlike those of *V. rufidulum* only smaller and lighter colored.

STEM: Slender, pubescent, gray-brown on first year stem; light gray-brown on second, glabrous; pith—solid, white, ample.

Viburnum obovatum is a densely twiggy, upright ascending, large shrub or small tree, the only thing small being the leaves. Habit is rather wild and splaying with a 10-year-old plant now 12' high and wide. The small leaves turn bronze-purple in fall-winter and persist into the New Year during mild winters, 15°F and above. Leaf persistence and winter coloration varies from plant to plant and year to year. In Athens, primarily evergreen in the compact types with foliage remaining green or tinged red-purple. Small, white flowers in 1 3/4 to 2 1/4" diameter cymes open with the emerging leaves, April in Athens. Flowers are not in any sense spectacular. Fruits are 1/4 to 1/3" diameter, ellipsoidal to spherical, red to shiny black drupes. Adapted to wet soils in the wild. Supportive of drier situations under cultivation. Semi-shade to full sun for best growth. Have seen in Tampa, FL landscapes. Also, more compact cultivars utilized in coastal North Carolina landscapes. I believe that the compact selections will become important components in Zone (6)7 to 9 landscapes. In many respects, they resemble evergreen *Ilex crenata* and *I. vomitoria* but the white flowers literally froth the foliage in late March–April for 2 to 3 weeks. The stems are supple, easily pruned, and regenerate new shoots. 'Mrs. Schiller's Delight' (smallest) and 'Reifler's Dwarf' have proven outstanding in our Georgia trials. South Carolina to Florida and Alabama. Zone 6 to 9.

CULTIVARS: Ten accessions of *V. obovatum* are growing in our UGA trials. I have yet to witness insects, diseases, or drought- or heat-related maladies. These cultivars range from compact, rounded shrubs like 'Reifler's Dwarf' to the upright, open 'St. Paul'. The compact clones would make great alternatives to the dwarf hollies like 'Carissa', 'Rotunda', 'Helleri', and 'Shillings'. Foliage on these compact forms has remained completely evergreen, with dark green to wine-red winter coloration. All produce abundant white flowers that shroud the foliage. Truly amazing that the species has not been domesticated to any degree for everyday landscape use in Zones 6 to 9. In November 2006 I witnessed three new compact introductions, Bright 'n' Tight™, Snow Fury™, and Specmaker™, from Steve Reifler. All were growing in 3-gallon containers, and Snow Fury™ was the densest, with the most aesthetic, lustrous dark green foliage.

'Christmas Snow'—Grew 5 1/2' by 4 1/2' in three years. This form has an upright habit that is more open than most cultivars but tighter than the species.

'Lord Byron'—Upright in habit, with larger leaves than the species. It is a hybrid with *V. rufidulum*. Flowers occur at all the nodes, making a great show. Observed at Hawksridge Nursery, Hickory, North Carolina.

'Mrs. Schiller's Delight'—The most compact in the UGA trials, growing to 14" by 3' in three years. It produced abundant flowers and lustrous dark green foliage. Would make a great grouping or mass planting.

'Reifler's Dwarf'—One of the first in the UGA collection, reaching 3 1/2' by 4 1/2' after five years. It has lustrous dark green foliage that is sometimes red-purple in winter and abundant white flowers. Certainly an eye-catcher, and many visitors ask about its identity.

'St. Paul'—A rather loose, open selection, attaining 12' by 8' in five years. Foliage and flowers are sparse compared to 'Reifler's Dwarf'. Flowers open earlier than the dwarf types, late March 2006 at the JC Raulston Arboretum, Raleigh, North Carolina. Perhaps more attractive than the species, which can grow larger and is open and splaying.

'Whorled Class'—Unique by virtue of the 3 leaves per node—hence the name. Growth habit is dense, compact, 2 1/2' by 3 1/2' after three years. Lustrous dark green leaves. The white flowers are not as abundant as on 'Reifler's Dwarf' and 'Mrs. Schiller's Delight'. 'Best Densa' is similar, if not the same.

Viburnum opulus L. — European Cranberrybush Viburnum

(vī-běr'num op'ū-lus)

LEAVES: Opposite, simple, similar to *V. trilobum*, with rather shorter, more-toothed lobes, 2 to 4" long, as wide or wider, lobes pointed, base slightly cordate to truncate, dark green and glabrous above, pubescent beneath or sometimes glabrous; petiole—1/2 to 1" long, with a narrow groove and a few large disk-like glands of a concave nature.

BUDS: Plump, 2-scaled, green-red-brown, 1/3 to 1/2" long, glabrous, shiny, scales connate (fused at edges).

STEM: Light gray-brown, glabrous, smooth, ribbed, rather stout.

SIZE: 8 to 12' possibly 15' in height, spread 10 to 15'.

HARDINESS: Zone 3 to 8.

HABIT: Upright, spreading, multi-stemmed shrub, often with arching branches to the ground creating a rounded habit, thicket forming in its native habitat.

RATE: Medium.

TEXTURE: Medium in foliage; medium to coarse in winter, can look "ratty" in winter.

LEAF COLOR: Good glossy dark green in summer, changing to yellow-red and reddish purple in fall; not a consistent fall coloring shrub, often leaves show no change, simply falling off green.

FLOWERS: White, outer ring of 3/4" diameter flowers sterile and showy, inner flowers fertile and inconspicuous, anthers yellow, creating a pin-wheel effect, May, borne in 2 to 3"(4") diameter, flat-topped cymes, flowers are handsome and interesting because of unique combination of sterile and fertile flowers in same inflorescence; slightly off-odor but only noticed with nose-to-flower symbiosis.

FRUIT: Berry-like drupe, bright red, ripening in September–October and persisting into winter, each fruit is about 1/4 to 1/3" diameter and globose in shape; the fruits often shrivel through the winter months and take on the appearance of dried red raisins.

CULTURE: Transplant balled-and-burlapped or from containers, one of the easiest viburnums to grow; adaptable to extremes of soil and in its native haunts is particularly rampant in wet or boggy situations; pH adaptable; large canes should be thinned out; fruits best in full sun but will stand partial shade.

DISEASES AND INSECTS: Often infested with aphids (plant lice) but this is more common on the cultivar 'Roseum'; can be easily controlled; borer has been a problem in the Midwest; viburnum beetle.

LANDSCAPE VALUE: Shrub border, screen, large areas, massing, excellent for its showy flower and fruit display; weed-like in Midwest and East as birds have planted it with abandon; the following cultivars may prove superior to the species.

CULTIVARS:

'Apricot'—Listed in the RHS Plant Finder 2006–2007. Possibly refers to fruit color.

'Aureum'—New growth a reasonably good yellow but soon fades to rather sickly yellow-green; the color is either lost (to green), or the foliage may burn in hot climates. Slower growing than the species, it has a rather limited landscape appeal. Flowers and fruits are like the species. Grows to 12' high and 10' wide and requires some shade. There was a 10' by 8' foot, dense, compact shrub at Hillier, June 30, 1999, with aphid damage on young growth. The yellow color was only on the young growth.

'Bulliton'—Listed by the Dawes Arboretum, Newark, Ohio, without supporting information.

var. *calvescens* Rehd.—Almost glabrous in all its parts, the petiole longer than the species, 1 1/4 to 1 1/2", and the anthers dark purple. I observed two plants at the JC Raulston Arboretum, Raleigh, North Carolina, that are performing well. I see little difference between this and the variable species. Certainly the anthers were not purple on plants I observed. The fruits are red. Flowers open early to mid May at the JC Raulston Arboretum. Appears to be smaller than straight species. A forma *flavum* of this variety, with yellow anthers and fruits, is known. Variety *calvescens* is often listed as a variety of *V. sargentii*. The leaf characteristics, however, parallel those of *V. opulus*. GRIN merges this into *V. opulus* var. *sargentii* (Koehne) Tak.

'Compactum'—An excellent plant where space is limited as it matures to one-half the size of the species in height and is extremely dense in habit. I witnessed many plants that were 6' high in England. Excellent

in flower and fruit; the red fruits make a brilliant show. Fall color is often a formidable red. Excellent in masses. Probably should be considered over the species in the smaller, more restricted planting areas of the modern landscape. I have been told that stem borers can be a problem. This is an excellent plant when properly grown. I witnessed a plant at Hillier, 10' high and wide, on May 31, 2006 with the flowers just opening. Appears to be slightly later than the species. Some question in my mind if this plant was a true 'Compactum'.

'Cream Puff'—A small form I witnessed at Bailey Nurseries, St. Paul, Minnesota.

'Elixir' and 'Krasnaya Grozd'—The most promising selections of a Russian breeding program to increase fruit yield and content of biologically active substances as well as to reduce the bitter taste of the fruit.

'Fructuluteo' ('Fructo-Luteo')—Pale yellow fruits turning rich yellow-tinted pink. This is a large form, growing to 10' high. Known in cultivation from about 1901 (see Kenyon, Lloyd. *Viburnum*. NCCPG, Stable Courtyard, Wisley, Woking, Surrey, England.).

'Harvest Gold'—Leaves that are richer yellow than 'Aureum', but it is not much different otherwise. I observed this form at Hillier.

'Leonard's Dwarf'—Have only seen described in Forest Farm's 1997 fall catalog. Reads like 'Compactum' and/or 'Nanum'.

'Losely's Compact'—Listed by Dawes Arboretum, Newark, Ohio.

'Nanum'—Dwarf form, much-branched and dense, 18 to 24" in height and one-and-a-half times that in spread. I have seen specimens between 4 and 5' high and wide. Supposedly never flowers or fruits, but, again, I have seen several isolated flowering and fruiting specimens. Makes a good filler or facer plant; can be used for low hedges. Will not withstand wet, poorly drained conditions, and in wet weather contracts significant leaf spot. Leaves range from 3/4 to 1 1/2" in width. Eugene W. Coffman, Ridge Road Nursery, Bellevue, Iowa, reports a branch sport of 'Nanum' that is slower growing and more compact. Listed as originating about 1841 in France.

'Nanum'

'Notcutt's Variety' ('Notcutt')—More vigorous (to 12') than the species with larger flowers and fruits and excellent maroon-red fall color.

'Park Harvest'—New to me until 1999, when I witnessed a large plant (10') at Hillier. Leaves are yellow initially, greening with time, possibly not as potent as those of 'Aureum'. 'Park Harvest' is akin to 'Harvest Gold'.

'Pohjan Neito'—A clone of the species, offers abundant inflorescences and significant cold hardiness. Selection and naming resulted from comparative field trials at five sites in Finland from 1989 to 1993.

'Roseum' ('Sterile')—Commonly known as the European snowball or guelder rose. This form has sterile flowers and is extremely showy in flower; the 2 1/2 to 3" wide inflorescences literally cover the shrub in mid to late April (Athens). It was in full flower May 12, 2006 at the 3,000 foot elevation in Fancy Gap, North Carolina; likewise on May 29, 2006 at Hinton Ampner near Winchester, England. This is an heirloom favorite, more apt to be located around older residences. Aphids infest this form quite heavily and often distort the young leaves and stems. The flowers are an apple-green in the early stages and change to white, remaining effective for a long period. A 20-year-old specimen in Fargo, North Dakota, showed no dieback although temperatures dropped as low as -30°F. A pink-flowered form is reported, but this I have not observed; however, the aging inflorescence sometimes assumes a slight pink tinge. Known since the 16th century. Grows 10 to 12' high and is a vigorous form. I recorded an 8' by 10', dense, broad-mounded shrub with leaf spot at Hillier, July 1, 1999.

'Variegatum'—Several cream- and white-variegated ('Tatteri') forms with unusual names are listed in English literature.

'Xanthocarpum'—Yellowish gold fruits that are quite attractive and often persistent, becoming translucent golden-yellow after frosts; a nice color complement to the red-fruited type. I have seen in England on several occasions. Worth considering! Will grow 8 to 10' high. Most mature plants I observed were smaller, in the 6 to 8' range. Habit is much more compact and rounded than 'Fructuluteo' and more aesthetic. There was a 7' by 8', rounded, dense plant at Hillier, July 1, 1999. A plant at Hillier was 12' by 15' in full flower, odor not offensive, on May 31, 2006. Introduced in 1910 by Spaeth of Germany.

PROPAGATION: Seed, 60 to 90 days at fluctuating temperatures of 68 to 86°F followed by 30 to 60 days at 41°F. Russian work reported harvesting seeds in September, clean, wash, and stratify in peat at ~45°F, with germination the following June–July. Cuttings are easy to root. I have had 100% success with softwood and greenwood cuttings.

NATIVE HABITAT: Europe, northern Africa and northern Asia. Cultivated for centuries.

Viburnum plicatum Thunb. f. *tomentosum* (Miq.) Rehd. (GRIN lists as a variety; everyone else, a forma.) — Doublefile Viburnum
(vī-bēr'num plī-kā'tum tō-men-tō'sum)

LEAVES: Opposite, simple, broad-ovate to oblong-ovate, sometimes elliptic-obovate, 2 to 4" (5") long, 1 to 2 1/2" wide, acute or abruptly acuminate, rounded to broad-cuneate to cordate, dentate-serrate, dark green and nearly glabrous above, stellate-pubescent beneath, with 8 to 12 pairs of nearly straight, impressed veins; petiole—1/2 to 1" long.

BUDS: Vegetative buds-naked, foliose, pubescent; flower buds-valvate, angular, tan-brown, hairy, appressed to stem or divergent.

STEM: Young branches stellate tomentose; older branches dark gray or brownish, orangish lenticels, many small branches (2 at node) forming a fishbone effect.

SIZE: 8 to 10' in height, usually slightly wider than tall at maturity (9 to 12'), one old plant at Bicton outside Bristol, England, was 10' tall and 20' wide; have seen this plant run the gamut in terms of size.

HARDINESS: Zone 5 to 7(8); Morton Arboretum reported *V. plicatum* f. *plicatum* and f. *tomentosum* are killed to the ground on a sporadic basis.

HABIT: Horizontal, tiered branching, creating a stratified effect, appearing rounded to broad-rounded at maturity.

RATE: Medium.

TEXTURE: Medium in foliage, medium in winter, can prove respectable in winter because of clean grayish brown branches and horizontal habit.

LEAF COLOR: Leaves emerge early, often by the first or second week of March in Athens, GA; dark green with maturity, veins are impressed creating a ridge-furrow effect; fall color is consistent reddish purple, leaves are borne opposite along the stems and tend to hang down creating a "dog-eared" effect.

FLOWERS: White, no fragrance, outer flowers sterile, 4 to 5 lobes, 3/4 to 1 1/2" wide, pure snow white; inner flowers fertile, not showy, May (mid-April, Athens), borne in 2 to 4" (up to 6") diameter flat-topped cymes which are borne on 2" long peduncles above the foliage creating a milky way effect along the horizontal branches; a choice specimen of Doublefile Viburnum is without equal.

FRUIT: Drupe, egg-shaped, 1/3" long, bright red changing to black, (June, Athens) July and August, usually devoured by birds before completely ripened; one of the earliest viburnums to display excellent fruit color.

CULTURE: Fibrous rooted, transplants well, demands moist, well-drained soil; from my own observations this plant will not tolerate heavy, clayey, poorly drained soils; I have grown well-branched, 3 to 4' high specimens in two growing seasons from cuttings without special care; received several comments about stem dieback which does occasionally occur; old overgrown or ratty specimens on campus are cut back

to 12" from the ground and rejuvenate quite nicely; in Zone 7 the plant is spectacular in April and May but heat and drought of the summer often induce marginal leaf necrosis; some shade, supplemental water, and mulch are recommended in the South.

DISEASES AND INSECTS: None serious, although I have observed stem dieback in wet areas; I am not sure if the problem was of a pathological or physiological nature.

LANDSCAPE VALUE: Possibly the most elegant of flowering shrubs; easily the biggest resided at Swarthmore College, fully 15 to 18' high and 20' or more wide; a choice specimen when placed near red brick buildings where the snow white flowers are accentuated; massing, screen, shrub border; blends well into a border as the horizontal lines break up the monotony of upright growing shrubs; could be integrated into foundation plantings especially corner plantings where it would help to soften vertical lines and make the house appear longer; I witnessed tremendous winter kill during the difficult winters of 1976–77, 77–78 throughout the Midwest (–20 to –25°F); large, well-established, 8 to 10' high plants in the President's Garden on the Illinois campus were killed; I am estimating the break point for injury in the –15°F or lower range; at Orono, ME, Cappiello reported moderate to severe dieback on *f. tomentosum* and 'Shasta'.

CULTIVARS: The taxon, *V. plicatum f. plicatum*, Japanese Snowball Viburnum, by all botanical standards, possesses sterile, 2 to 3" diameter, rounded, white flowers and, hence, cannot reproduce itself since fruits are not formed. Similar in all respects to Doublefile except for carnation-like, snowball flowers and upright growth habit to 15' high. The flowers are borne in 2 ranks along the arching branches and make a spectacular show in May for 2 to 2 1/2 weeks. This has proven to be an excellent plant for Zone 7 conditions provided there is ample root moisture. Several plants on the Georgia campus grew 15' high and wide and were spectacular in flower. Generally, *V. plicatum f. plicatum* flowers 2 to 3 weeks later than *V. p. f. tomentosum*.

***Viburnum plicatum f. plicatum* cultivars:**

'Chyverton'—Low, wide-spreading habit. Flowers all sterile as in typical *f. plicatum*. A mature plant grew 4' high and 20' wide in 24 years. At Stourhead, England, there was a relatively low-growing, wide-spreading form with abundant flowers. This form might be welcome in American gardens since the principal type in cultivation is upright, large, and coarse. Introduced by Nigel Holman in 1964 from cuttings he collected from the garden of Lionel Fortescue.

'Grandiflorum'—A fine form with abundant, slightly larger flower heads than *f. plicatum* and leaves that are wider, more rounded, with veins tinted red below. White flowers are occasionally tinted pink at petal edges. Earlier flowering than most *f. plicatum* types, the plants I have seen showed an accentuated horizontal branching pattern. This form is worth seeking out. Witnessed plants 12' high, 10 to 12' wide at Hillier, May 31, 2006. Introduced by Hesse Nurseries, Germany, in the late 1800s.

'Kern's Pink'—See under 'Rosace'.

'Leach's Compacta'—A dwarf form that grows 4' by 3', with double, white flowers in snowball inflorescences. Foliage is red-burgundy in fall. I have not witnessed this in cultivation.

'Mary Milton' ('Mary Melton')—Akin to 'Rosace' with consistent pink, snowball flowers. Starting to make the garden rounds. Matures 8 to 10' high. I have read descriptions that flowers open white and age to pink. The lone flowering plant I witnessed (April 23, 1998, Athens, Georgia) was green-pink in bud, opening light pink and fading white; it looked different from 'Rosace'. I know several gardeners who have purchased this cultivar, and all have flowered white. Not as vigorous as 'Rosace'.

Newport® ('Nanum Newport')—Have seen it a number of places in the Midwest. The habit is extremely dense, mounded, with smaller dark green leaves than the species that turn burgundy in fall. Five to 6' high and wide; 4' by 4' in five years in the University of Georgia trials. Initially, I did not think much of flower quality, but reasonably mature plants at Spring Grove, in Ohio, flowered profusely. Flowers are a looser, snowball type that are nestled among the foliage, and since the plant is so dense, their effect is reduced compared to *f. plicatum*, but still appreciable. Survived –20 to –30°F in Bellevue, Iowa. Plants that were severely killed back (not eliminated) at –25°F in Spring Grove in January 1994 had grown back to 3 to 4' high by January 1998. Flowered later than 'Popcorn' by seven to ten days in the Georgia trials. A Lake County Nursery introduction.

'Pink Dawn'—Described by Kinsey Gardens, Knoxville, TN as a hot-pink, early-flowering type, flowers 2 1/2" across. New foliage is bronzy-purple; as the leaves mature, they hold some of this color. Vigorous upright habit. Although listed as *f. plicatum* may be a form of *V. farreri*. This could be a rename of 'Rosace'.

'Pink Sensation'—Pink-emerging snowball flowers that turn white with maturity. Leaves bronze-tinted maturing green. Opens mid April in Raleigh, North Carolina, with white inflorescences mixed with pink, reflecting reversion. Flowered May 1, 2006 at the JC Raulston Arboretum, where I first observed this form in 2005. Might be another rename for 'Rosace'.

'Popcorn'—An introduction from David Leach, North Madison, Ohio, and the best of the *f. plicatum* litter. Vigorous but tight in habit with leathery, dark green leaves that are more heat and drought resistant than the species. The 3" or slightly larger, white snowball flowers appear in profusion in April (April 13, 2005, Athens). Earlier to flower than the other *f. plicatum* cultivars. I can look down the row of *f.*

plicatum types, and in late summer this is the most pristine. Probably 8 to 10' high. Has not spread as much as 'Grandiflorum' and 'Rotundifolium'. Hardy to -23°F. Nine feet by 9' in five years in Georgia trials.

'Roseace'—Selected and introduced around 1953 (1957, according to Kenyon 2001) by Carl Kern of Wyoming Nursery, Cincinnati, Ohio, for its medium-pink flower and bronze tinged foliage. I believe this is the same as 'Kern's Pink', 'Pink Sensation', and possibly others; as I saw 'Kern's Pink' the color was on/off-pink with some inflorescences pink, others white, and still others mixed. Don Shadow has grown 'Rosace' for years and tried to stabilize the chimera, i.e., pink flowers. The plants are beautiful in flower, with pink being genetic and not environmentally or culturally regulated. In fact, the mix of pink and white inflorescences on the same plant is beautiful. In full flower April 25, 1994 at Winchester, Tennessee. This form has reasonable vigor and plants should mature between 6 to 10'.

'Rotundifolium'—A form with round leaves which are 1 to 2" long and 1 to 1 1/2" wide. It is more refined than f. *plicatum* and grows 7 to 8' high and wider at maturity.

'Sawtooth'—Like f. *plicatum*, has large, coarsely toothed, dark green leaves and large, snowball flowers. It has not performed well in UGA trials: it grows next to 'Popcorn', and the greatness of its neighbor is easily understood. 'Sawtooth' has been a weak grower and really languished in the heat.

Triumph® ('Trizam')—A rounded, dense, compact form—5 to 6' high and 6 to 8' wide—with thick, quilted dark green foliage, white typical snowball flowers, and few fruits. Derived from Newport® and described as prolific flowering. As I observed the plant in proximity to Newport®, it was taller and less dense. A Lake County Nursery introduction.

Viburnum plicatum* f. *tomentosum cultivars: Many and varied. For example, 'Shasta', originally described as 6' high, has grown over 12' high in Georgia. Certainly beautiful but too big for most gardens. The moral: choose wisely from the cultivars.

'Cascade'—A seedling of 'Rowallane' selected in 1971 in the Netherlands, with wide-spreading branches. Inflorescences are umbrella-shaped, 2 1/2 to 4" across, with large, showy sterile outer flowers that arch slightly at the middle, creating a cascading effect. Red fruits are produced in abundance. Good burgundy fall color. I witnessed in flower at Crathes Castle Garden, Scotland, in late June 1995, and it is actually better than the text: a must-have for serious doublefile junkies. On May 25, 2006, Bonnie and I were assessing the *Viburnum* collection at RHS Wisley, and the only doublefile that was easy to identify from a distance was this selection; that plant was 6 to 7' in height. I have serious qualms about 'Cascade' ultimately growing taller than 'Mariesii', even though the literature states it so, having observed greater than 15' high 'Mariesii'.

'Dart's Red Robin'—Broad-spreading to 5' (probably more like 6 to 10' high), with dark green leaves, profuse, white-tinged pink flowers in umbrella-shaped inflorescences, and deep red fruits, profusely borne. Inflorescences are smaller (about 3") than the typical f. *tomentosum*. I have observed in heavy fruit at RHS Wisley in late July; Wisley plant was 9' high, straggly and leggy, on May 25, 2006. Have seen plants labeled 'Dart's Red Robin' that appeared to be 'Lanarth'.

'Everblooming'—Listed but I have not observed. I suspect may be the same as 'Summer Snowflake'.

'Fireworks'—Produces 6" white flowers on an 8' by 6' shrub that is hardy to -23°F. Fertile flowers and pedicels are reddish and surrounded by the pure white, outer, sterile flowers. Developed by David Leach, North Madison, Ohio.

'Igloo'—Originated as a chance seedling at Winterthur Gardens, Delaware. The plant develops a wide-spreading, mounded habit, 6' by 12', that resembles an igloo in outline. Lacecap flowers occur in 4 to 5" wide, flat-topped cymes in May and are followed by dark red fruits in July. Ken Day of Winterthur's nursery speculates that 'Mariesii' is the parent. Selected in 1991. Survived -20 to -30°F in Bellevue, Iowa.

'Lanarth'—Larger flowered from than typical doublefile, with ray flowers up to 2" in diameter and larger. It is probably confused with 'Mariesii'. As I have observed it, a very beautiful selection, 12 to 14' high and wide; a wonderful plant at the Arnold Arboretum was 8' by 10 to 12'. Habit is flat-topped, with a strong, distinctly horizontal branch architecture. One of the best forms. Introduced before 1930 from Lanarth, Cornwall, England.

'Magic Puff'—A compact, rounded habit, 4' high and 5' wide, typical lacecap flowers, red to black fruits, clean dark green leaves, and wine-red fall color. Best in Zone 5, although listed as 4. Introduced by Willoway Nurseries, Avon, Ohio.

'Mariesii'—Large ray flowers, up to 1 3/4" in diameter, raised on a 2 1/2" high peduncle that brings the flowers above the foliage. Habit is distinctly horizontal, and a plant in full flower is a magnificent sight. The leaves may turn reddish purple in fall. I have read conflicting accounts; some state 'Mariesii' is the best fruiting form, others that fruit is sparsely set. I have not resolved this discrepancy in my own mind—as with many viburnums, lack of fruit set may be due to absence of a cross-pollinator. Leaves perhaps lighter green in summer than other types. Many plants offered as 'Mariesii' are, in fact, something else. 'Mariesii' bears leaves that have extended apices (long-acuminate) with a slight drooping tendency. Plants over 10' high in England are common. Although cited as lower-growing than

- 'Lanarth', this is not absolute. I have observed 15' high 'Mariesii' in England; witnessed a 12' by 14' plant at RHS Wisley, May 25, 2006. Introduced about 1877 from Japan by Maries. Killed in Bellevue, Iowa, after -20 to -30°F, while 'Igloo', 'Shasta', and 'Shoshoni' survived.
- 'Molly Schroeder'—Described by Dan Hinkley as a dependably pink-flowered selection with persistent blooming throughout the summer. Grows 8' high and 5' wide with horizontal branches. Dan's observations of pink flowers is based on Bainbridge Island, Washington, conditions. The pink may fade in the heat of the Midwest, East, and South. Another reference noted that the flowers are consistently pink even when grown under poly. Observed in Georgia and early flower was pink. In Chapel Hill garden faded to almost white.
- 'Nanum Semperflorens' ('Watanabei', 'Watanabe Nanum')—A compact form introduced from Wada's Nursery in Japan. Habit is dense, flowers smaller than the type but making a good display. May grow 5 to 6' high. Flowers on and off through summer. Sparse fruit set. Supposedly grows very dwarf; some literature states less than 2' high, but I don't buy this designation. Discovered by Mr. Watanabe in the foothills of Mount Fuji and propagated by his firm in the 1950s. A plant at the JC Raulston Arboretum is 6 to 7' high, 8 to 10' wide. Not the same as 'Summer Snowflake'.
- 'Pink Beauty'—Handsome form with pink flowers. Specimens I have observed had leaves and flowers slightly smaller than typical doublefile, but the deep pink petal color was outstanding. Somewhat upright in habit, generally smaller in all its parts. Flower color develops as petals age; this pink coloration is variable over my traveling years. I observed a plant at Sissinghurst that one season was outstanding pink; on later visits, flowers were white, and I was not sure if it was the same plant. I have on occasion discovered heavily red-fruited specimens. Fruits ripened on June 3, 2004 at the JC Raulston Arboretum; not as pubescent on the lower surface as typical f. *tomentosum*. In the 6 to 10' range, less in spread. A 10' by 7' plant at Hillier in 1999. Appears that temperature affects petal color, and there is no absolute that 'Pink Beauty' will be just that. In fact, on May 31, 2006 at Hillier, two specimens of 'Pink Beauty' were snow-white, and the English spring was cool and moist.
- 'Roseum'—Sterile flowers that open white and gradually fade to an excellent deep pink. It also has smaller leaves and is less vigorous than the type. In several respects 'Pink Beauty' and 'Roseum' are similar and may be one and the same. From the Brooklyn Botanic Garden.
- 'Rowallane'—Less vigorous than 'Lanarth' and 'Mariesii', with smaller, broadly ovate, short acuminate leaves. Flowers are not as wide but the ray-florets are still large and form a uniform circle around the sparse, fertile inner flowers. Supposedly fruits heavier than 'Mariesii'; I witnessed in flower in late June at Rowallane. Best description is haystack-shaped. Inflorescences smaller than typical but produced in wondrous quantities—an amazing show. Plant was 8 to 10' high, 6 to 8' wide. Selected and distributed before 1942 in Rowallane Gardens, Northern Ireland, but possibly raised at Rostrevor from seed collected by E. H. Wilson.
- 'Shasta'—A tremendous 1979 introduction from the U.S. National Arboretum and Don Egolf's breeding program. It is a broad, horizontally branched shrub, originally described as 6' high by 10 to 12' wide at maturity. The abundant, 4 to 6" wide inflorescences have sterile, marginal, pure white florets about 1 1/4 to 2" wide; the 5 to 15 inner florets, 1/2 to 1 1/2" wide, are dispersed among the fertile flowers. The flowers are followed in July by bright red, maturing to black fruits. This excellent plant is now embedded in the psyche of American gardeners. I nurtured a supposed specimen of 'Shasta' into a 7' by 8' specimen, only to decide it was just the species or a cheap imitation. My garden heart was broken, especially when I saw the real McCoy with wide-spreading, horizontally accentuated branches and immense inflorescences that literally smothered the leaves. Will become a large plant—easily 10' or more high and wider at maturity. Plants in the UGA Botanical Garden are over 12' high. Survived -20 to -30°F in Bellevue, Iowa. In 1954 a select *V. plicatum* f. *tomentosum* was crossed with 'Mariesii'; from the second generation of this hybrid population, a superior plant was selected in 1968, named and released in 1978, as 'Shasta'. See Egolf, Donald R. 'Shasta' *Viburnum*. *HortScience* 14:78–79 (1979) for additional information.
- 'Shasta Variegated'—Leaves that resemble 'Shasta' in shape and size, with yellow-green marbling; some are heavily yellow-marbled. A branch sport found by George Krauth, Estill Springs, Tennessee. Apparently an unstable chimera and never fully introduced into cultivation. George is closing his business so the fate of this is unknown.
- 'Shoshoni'—A seedling of 'Shasta' bred by Egolf, has performed well in UGA trials and is one-third to half the size of 'Shasta', with all the attributes of that form on a smaller scale. I noted prodigious fruit set on the trial plants: probably related to prevalence of pollinators. The parent plant was 5' high and 8' wide in 17 years; 7' high and wide in five years in the UGA trials. The dark green leaves are 2 1/2 to 6" long, 1 1/4 to 2 1/2" wide, and turn dull purplish red in fall. The flowers occur in 3 to 5" wide, flat-topped cymes in April–May; full flower on April 27, 2004, Chapel Hill, North Carolina. The 5 to 7 outer, sterile, showy florets average 3/4 to 1 1/4" long and 1 to 1 3/4" wide with 50 to 130, greenish white, perfect flowers in the center. The ovoid, 1/3" long, 1/5" wide drupe ripens red and matures to black. Fruits coloring June 1–15, 2006 in Athens. Never really jumped out of the starting blocks, but I have

seen this at the National Arboretum and, indeed, it is worthy of consideration for the smaller garden. An Egolf/U.S. National Arboretum introduction (see *HortScience* 21:1077–1078 (1986) for additional information). Survived –20 to –30°F in Bellevue, Iowa.

'St. Keverne'—Large form—10 to 12' high and wide. Inflorescences are umbrella-shaped, and it seldom produces fruits. Better than typical species.

'Summer Snowflake' ('Fujisanensis', 'Mt. Fuji')—A tall-growing, rather narrow selection with smaller leaves, flowers, and fruits than the species. The ability to flower prominently in spring (April in Athens), then sporadically into November distinguishes it from other doublefile cultivars. Have observed plants 15' high and greater, with an 18' tall specimen still flowering on July 30, 1999 at Burncoose Nursery, Cornwall, England. I estimate plants will mature two to three times taller than wide. Has picked up steam in the U.S. nursery industry because it flowers over a long period. Not as cold hardy as 'Igloo', 'Shasta', 'Shoshoni', and Newport® ('Newzam'). Flattened to ground after –22°F in Louisville, Kentucky.

'Watanabei'—See 'Nanum Semperflorens'.

'Weeping Magic'—Pendulous branches, which produce a low-mounding habit. It is wider than high at maturity, approximately 4' high by 6' wide; young container plants develop the shape of a bird's-nest spruce (*Picea abies* 'Nidiformis'). Leaves are light green; defoliation occurs before any fall color. Typical lacecap flowers and fruits. The smaller size and habit are unique. Introduced by Willoway Nurseries, Avon, Ohio.

'White Delight'—Described by Kenyon as a dense, upright plant, not as wide-spreading as 'Shasta'.

PROPAGATION: Cuttings—I have taken cuttings throughout the growing season and achieved 100% success with 1,000 ppm IBA, peat:perlite, mist; one of the easiest viburnums to root.

NATIVE HABITAT: China, Japan. Introduced 1865; the sterile form in 1844 by Robert Fortune.

Viburnum prunifolium L. — Blackhaw Viburnum

(vī-bēr'num prō-ni-fō'li-um)

LEAVES: Opposite, simple, broad-elliptic, ovate, obovate, occasionally rounded, 1 1/2 to 3 1/2" long, 1 to 2" wide, acute or obtuse, rounded at base or broad-cuneate, serrulate, dull to lustrous dark green above, pale below, glabrous or nearly so; petiole—not narrowly winged, 1/3 to 3/4" long, reddish.

BUDS: Vegetative and flower buds short-pointed, valvate, lead-colored, about 1/2" long, flower buds with a bulbous base.

STEM: Glabrous, usually short and stiff in nature, gray-brown, side branches present a hawthorn-like appearance.

SIZE: 12 to 15' in height by 8 to 12' in width, can grow 20 to 30' high, co-national champions are 25' by 32' in Westmoreland, VA and 26' by 35' in Silver Spring, MD.

HARDINESS: Zone 3 to 9.

HABIT: Round headed tree or multi-stemmed shrub, stiffly branched, similar to *Crataegus* in growth habit; Robinson described this species as a "puritan with a rigidity of character similar to some of the hawthorns"; have seen 20 to 25' high plants in tree form that were quite handsome.

RATE: Slow to medium.

TEXTURE: Medium in leaf; handsomely coarse in winter.

BARK: Unique, becoming black and blocky, similar to *Diospyros virginiana* and *Nyssa sylvatica*.

LEAF COLOR: Dark green, handsome, clean foliage in summer changing to purplish to reddish purple in the fall; various authorities have described the fall color as shining red, dull deep red to bronze; variable from plant to plant.

FLOWERS: White, actually creamy due to numerous yellow stamens, 1/4" across, early April, Chapel Hill, NC; borne in 2 to 4" diameter, flat-topped cymes with the emerging leaves; not overwhelming but certainly attractive.

FRUIT: Drupe, oval, up to 1/2" long, pinkish, rose and at maturity bluish black, bloomy, September through fall, fruit is palatable and has been used for preserves since colonial days; at Bernheim Arboretum on a magnificent early November day, a wandering group of demented plantsmen, led by Don Shadow, snacked on the fruits of a particularly heavy-fruited specimen; to watch purple-black juices oozing from the mouths of supposedly civilized men, well, it ranked with the greatest experiences of my life, thankfully no photographs were taken and the entire group is in denial.

CULTURE: Transplants well, adaptable to many soil types; sun or shade; does well in dry soils.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Interesting as a small specimen tree, massing, shrub border, groupings; habit is somewhat similar to hawthorns.

CULTIVARS: Kenyon lists 'Gladwyne', 'Holden', and 'Mrs. Henry Large'; none probably in commerce.

'Early Red'—New leaves emerging subdued red and developing burgundy in autumn. Offered by Fairweather Gardens, New Jersey.

Forest Rouge™ ('McK Rouge', 'McRouge')—Uniform habit, typical cream-white flat-topped inflorescences, and blue-black fruits. Deep glossy green foliage turns purple-red in autumn. Introduced by Dan Moore, McKay Nursery, Waterloo, Wisconsin.

Guardian™ ('Guazam')—Selected for the crisp, healthy green foliage that persists until fall (when it turns brilliant crimson-red), white flowers, blue-black fruits, and strong vigorous upright habit. Grows 10 to 12' high, 6 to 8' wide. A Lake County Nursery introduction, part of their Shepherd's Series™.

Knighthood™ ('Knizam')—Cream-white flowers in 4" diameter, flat-topped cymes; glossy, thickish, hunter-green foliage turns maroon to red; 12 to 15' by 6 to 8'; Jim Zampini introduction, Lake County Nursery.

Ovation™ ('Ovazam')—Columnar, 10' by 4'. New leaves are rosy pink and mature crisp celery-green. Self-scaffolding branches, good for hedging and limited space use. Hardy to Zone 3. Another member of Lake County Nursery's Shepherd's Series™.

'Summer Magic'—Produces red to pink new growth, leathery dark green mature leaves, and yellow to red fall colors on an upright habit, 8 to 10' high by 6 to 8' wide. Zone 5. Introduced by Willoway Nurseries, Avon, Ohio.

NATIVE HABITAT: Connecticut to Florida, west to Michigan and Texas. Introduced 1727.

RELATED SPECIES:

***Viburnum rufidulum* Raf.** — Rusty Blackhaw Viburnum, Southern Blackhaw
(vī-bēr'num rū-fid'ū-lum)

LEAVES: Opposite, simple, oval, ovate to obovate, 2 to 4" long, 1 to 1 1/2" wide, sometimes almost as wide as long, obtuse, or short acuminate, broad cuneate to almost rounded, leathery, serrulate, lustrous dark green above, pubescent below initially, finally glabrous; petiole—1/4 to 1/2" long, more or less winged, with rusty pubescence.

BUDS: Much like *Viburnum prunifolium* in shape and size but covered with short, dense, rusty brown hairs that set this species apart from the closely allied *V. prunifolium* and *V. lentago*.

Viburnum rufidulum, Southern or Rusty Blackhaw, has handsome lustrous dark green leathery foliage, more pubescent plant parts, and is slightly less hardy than the above species. Worthwhile specimen where it can be grown. I have developed a real fondness for this species and found it wild in the Athens, GA environs. Flowers cream-white, slight to no fragrance, early to mid-April (Athens), 1/3" across, in up to 5" diameter cymes. Fruit is a 1/2 to 2/3" long, ellipsoidal, bloomy dark blue drupe. The buds are covered with a deep rich rusty brown pubescence which distinguishes it from any viburnum in this book. The habit can be shrubby or tree-like and larger branches develop a blocky, *Cornus florida*-like bark. The leaves may turn a rich burgundy in fall. Excellent plant and should be used more widely. Will grow 10 to 20' high under typical landscape conditions but may reach 30 to 40' in the wild. National champion is 32' by 28' in Knox County, TN. Occurs as an understory plant in the Piedmont of Georgia and tends toward an open habit in such locations. In full sun, it becomes more dense. An upland species in well-drained woodlands, hedgerows and fencerows. Displays excellent drought tolerance and has withstood -25°F in Midwest without damage. A compact form would be a tremendous garden addition. On the Georgia campus, a group of seedlings were planted in 1993. They are now 6 to 10' high and each is different. I have propagated the most dense, lustrous dark green leaf form but it is the largest, now about 10' high. Virginia to Florida, west to Illinois and Texas. Introduced 1883. Zone 5 to 9.

CULTIVARS:

Emerald Charm™ ('Morton')—Glossy dark green leaves, burgundy in fall, and is cold hardy. Matures 10 to 12' high by 8 to 10' wide. Originated from seed collected in Webb City, Missouri, by the Morton Arboretum and introduced through Chicagoland Grows®.

'Royal Guard'—Excellent glossy dark green foliage that turns rich burgundy to deep maroon in autumn. Supposedly grows 12' by 6', although I have read spreads of 10 to 20'. Flowers and fruits are similar to the species. Hardiness is often debated, but 15' high specimens have withstood -20 to -25°F at the Morton Arboretum. A 10' high plant at the JC Raulston Arboretum flowered April 24, 2005; it did not impress any more than the average species seedling I see at woodland edges in the Southeast.

Viburnum ×rhytidophylloides J. Sur. — Lantanaphyllum Viburnum (hybrid of *V. lantana* × *V. rhytidophyllum*)

(vī-běer'num rī-ti-dō-fil-oy'dēz)

Similar to *V. rhytidophyllum* except leaves broader and less rugose, not as elongated and a degree less dark green and leathery. Leaves 4 to 8" long. Another good trait is the flower bud which is tightly clustered like a cauliflower where *V. rhytidophyllum* is larger and looser. Usually deciduous in North; often semi-evergreen in Zone 7.

SIZE: 8 to 10', possibly 15' in height, spread would probably equal height at maturity; robust shrub often exceeding the first mentioned size range.

HARDINESS: Zone (4)5 to 8 depending on cultivar.

HABIT: Upright, spreading shrub with slightly arching branches; eventually somewhat rounded in outline; large, robust and coarse.

RATE: Medium.

TEXTURE: Medium to coarse in summer and winter.

LEAF COLOR: Dark leathery green above, light gray to gray-brown and extremely tomentose beneath, the foliage has a bold coarseness which is quite attractive, leaves hold late often into November.

FLOWERS: White (creamy), unpleasantly scented, borne in 3 to 4" diameter, flat-topped cymes; flowers in early to mid-April in Athens; mid-May, Urbana, IL.

FRUIT: Drupe, reddish changing to black, late August through September into fall, can be excellent depending on cultivar and the presence of a pollinator; actually much like *V. lantana* in color transformations.

CULTURE: Transplants well, adaptable; sun or partial shade; best sited in a protected location; much hardier than *V. rhytidophyllum*; has performed well in the heat of Zone 7; can be located in full sun with good success.

LANDSCAPE VALUE: Possibly should replace *V. lantana* because of excellent foliage; could be utilized for screen, foundation plant, blended with other broadleaf evergreens; I had never seen a good fruiting specimen prior to 1977; since that time I have observed some magnificent specimens with a fruit character not unlike that of *V. lantana*, i.e., yellow-red-black; I have noticed that if *V. lantana*, *V. rhytidophyllum* and other clones of *V. ×rhytidophylloides* are close, fruit set is significantly better; many viburnums must be cross pollinated for good fruit set to occur; planting several plants of the same clone is not the answer.

CULTIVARS:

'Alleghany'—An Egolf/U.S. National Arboretum introduction selected from an F2 *V. rhytidophyllum* × *V. lantana* 'Mohican' seedling population in 1958 (1953 cross). Named and released in 1966. Actual 'Alleghany' resulted from a selfed seedling that produced the F2 population resulting in 'Alleghany'. Plants have very dark green, leathery leaves; abundant inflorescences; resistance to bacterial leaf spot; hardiness; and vigorous, dense, globose growth habit. The foliage, which tends to be deciduous to semi-persistent, is intermediate between the parental species (33 percent evergreen at Hillier on March 3, 1999). It is smaller than *V. rhytidophyllum*, and is more leathery than *V. lantana*. The rugose, coriaceous leaves are resistant to leaf spot and are highly ornamental. The abundant, yellowish white inflorescences in May are effectively displayed above the dark green foliage. For several weeks in September and October the fruits become brilliant red as ripening advances to black at maturity. In 13 years the original plant attained a height of 10 1/2' and a spread of 11'. This has proven to be an outstanding selection and is being successfully grown as far north as the Minnesota Landscape Arboretum, although it is not perfectly cold hardy. Has been a stalwart in Zone 7 but little known or grown. It is so superior to *V. lantana* that I do not understand the reasons for planting that species. 'Alleghany' was used by Pellett to develop 'Emerald Triumph'.

'Dart's Duke'—Large, leathery dark green foliage, 6 to 8" in length, and white flowers in 6" wide cymes. Often flowers in the fall like 'Willowwood'. Grows 8 to 10' high and wide. From Darthuizer nursery in the Netherlands.

'Holland'—Presented here only for historical purposes: it was apparently one of the first named hybrids between the two species, raised about 1925.

'Willowwood'—A form with excellent lustrous, rugose, dark green foliage and an arching habit. Has performed admirably in the Midwest, at times coming through the winter with foliage in good condition. A 15' by 10' plant at Hillier was 75 percent evergreen on April 26, 1999. I have seen this cultivar

flowering in October on the Purdue University campus, West Lafayette, Indiana. It is the result of a cross made in 1928 by Henry Tubbs of Willowood Farm, Gladstone, New Jersey. In Georgia, flowers in October–November and again in spring.

PROPAGATION: Cuttings, softwood and greenwood, 1,000 ppm IBA solution, rooted 100%; the cultivars are extremely easy to root from cuttings.

ADDITIONAL NOTES: Used by Dr. Harold Pellett as one parent to produce 'Emerald Triumph'. Cappiello reported that 'Alleghany' was more cold hardy than 'Willowood' in Orono, ME, although the former did suffer stem kill, the latter was killed outright.

Viburnum rhytidophyllum Hemsl. — Leatherleaf Viburnum

(vī-bēr'num rī-ti-dō-fil'um)

LEAVES: Opposite, simple, evergreen, ovate-oblong to ovate-lanceolate, 3 to 7" long, 1 to 2 1/2" wide, acute or obtuse, rounded or subcordate at base, entire or obscurely denticulate, lustrous dark green, glabrous and strongly wrinkled above, prominently reticulate beneath and gray or yellowish tomentose; petiole—1/2 to 1 1/4" long.

BUDS: Vegetative-large, rusty colored, tomentose, foliose; flower buds borne in semi-rounded cymes, 1 1/2 to 2" across, evident throughout winter and rather open compared to *V. ×rhytidophylloides*.

STEM: Gray to brown in color with stellate pubescence on young stems, older stems glabrous.

SIZE: 10 to 15' in height with a similar spread.

HARDINESS: Zone 5 to 7, although in severe winters will be killed to the ground; usually develops new shoots the following spring as the roots are not injured; -10 to -15°F is about the break point.

HABIT: Upright, strongly multi-stemmed shrub, often somewhat open with age, usually upright-rounded in outline.

RATE: Medium.

TEXTURE: Coarse throughout the year.

LEAF COLOR: Dark lustrous leathery green above, gray to brownish tomentose beneath, essentially evergreen in the North and with proper siting (in a micro-climate) will maintain most of its foliage; evergreen in the South.

FLOWERS: Yellowish white, slightly fragrant, mid-May (mid-April, Athens), borne in 4 to 8" diameter, 7- to 11-rayed, flat-topped cymes; the color is not outstanding but the quantity and size of the flowers are ornamental assets; the naked flower buds are formed in July–August–September of the year prior to flowering and are interesting because of large cymes on which they are borne.

FRUIT: Drupe, oval, 1/3" long, red changing to black, September, October through December; prior to 1973 I had never observed good fruiting on this species; in 1973 I found three specimens on the north side of a house in Urbana, IL, literally weighted down with beautiful red fruits; often viburnums are self-sterile and do not fruit heavily unless different clones are present; perhaps what I stumbled upon are three clones (seedlings) of Leatherleaf.

CULTURE: Transplants well, well-drained soil aids hardiness; shelter from wind and winter sun, tolerates heavy shade (3/4); -10°F will injure leaves; best where it is offered some protection; prune to ground to rejuvenate; not as content in heat of Zone 7 to 8, needs shade and moisture.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Excellent specimen where it can be grown without coddling; blends well with other broadleaf evergreens; possibly massing or as a background plant; everything is relative in life and even my great emotional ties to viburnums have influenced me unfairly in appraising the merits of this shrub; in the North it was welcome for the reasons enumerated; in the South the competition is so ferocious from other broadleaf shrubs that it is second class; the 10' high plant in our garden that my wife, Bonnie, loathed in the 1990 edition is now compost.

CULTIVARS:

'Aldenham' ('Aldenhamensis')—Did not appear much different from the species, at least the RHS Hyde Hall specimen I photographed May 1, 1999 did not. Pink-budded flowers open white in large cymes.

'Cree'—More compact than the species, oval-rounded, with lustrous dark green leaves that are 6" by 2". I have observed at the U.S. National Arboretum and the Sarah P. Duke Gardens and was not overwhelmed. A small plant in my evaluation tests is traveling nowhere—better than run-of-the-mill *V. rhytidophyllum*, but no reason to rejoice. Grew 8 1/2' by 8' in 14 years. Leaves in winter do not curl or

roll as profoundly as the species. Possibly more cold hardy. Produces abundant white flowers and red, maturing to black fruits. Introduced in 1994.

Fenceline™ ('Hefline')—Compact, columnar upright, more narrow and with increased leaf retention; thick dark green leaves; cream-white flowers in profusion late April–early May in Conover, NC; mature size estimated at 12 to 15' by 6'; has grown 8' by 4' in 7 years; introduced by Hefner Nursery, Conover, NC.

'Green Trump'—Darker green, more compact form of leatherleaf from the Netherlands. Observed at Swarthmore. Leaves appeared larger than typical. Otherwise, no great distinction from the species.

'Roseum' (also listed as forma *roseum* Rehd.)—Pink flower buds that open yellowish white. I have seen this form in England and indeed the buds are an attractive pink, not overwhelming. Dense 8' by 8' foot plant at Hillier, July 1, 1999. 'Wisley Pink' has rich rose-pink flower buds.

'Variegatum'—I had high hopes for this creamy white, irregularly variegated shrub but, after seeing it in England a few times, came away disappointed. The plant reverts, and it is often difficult to locate the variegated leaves. For the collector who has time to prune away the green shoots. A 10' high plant at Hillier had about 15 variegated leaves and 300 green leaves on May 31, 2006, some a mix of green-yellow-cream, a few yellow, and one or two cream.

PROPAGATION: Cuttings, I have taken firm cuttings throughout the growing season and achieved 100% success; use 1,000 to 3,000 ppm IBA to improve rooting.

NATIVE HABITAT: Central and western China. Introduced 1900.

RELATED SPECIES:

Viburnum 'Pragense', (formerly *Viburnum*

xpragense Vik.), (vī-bēr'num prag-en'sē), Prague Viburnum, is the result of a cross between *V. rhytidophyllum* and *V. utile*. It is an attractive evergreen shrub with lustrous dark green, 2 to 4" long, elliptic leaves. The flowers are pink in bud, opening creamy white, slightly fragrant and produced in terminal 3 to 6" wide, essentially flat-topped cymes in mid-April in Athens. This hybrid was raised in Prague in 1955 and is extremely hardy. There was a plant in the woody plant test plots at the University of Illinois which held up well under the rigors of midwestern winters. It survived -6°F in the Arnold Arboretum without foliage discoloration. I observed severe leaf burn (no stem or bud damage) at Spring Grove after exposure to -17°F. It will grow 10' or more and is suited to culture in Zone 5 to 8. It is easily propagated from softwood cuttings. The species has received considerable attention in the mid to lower South and is now grown by several major nurseries. The habit is upright oval to oval-rounded. The growth extensions are so vigorous that they must be pruned to achieve reasonable density. Extremely fast growing and makes a good screen, grouping or accent plant. Has much more ornamental charm than *V. rhytidophyllum* and based on my observations is hardier than either parent. In fact, in the Arnold Arboretum's viburnum collection, *V. xpragense* was 8 to 10' high, *V. rhytidophyllum* a die-back shrub, and *V. utile* did not exist. 'Decker' was selected by Decker Nursery, Ohio, for lustrous dark green leaves and pink-budded flowers that open white. Supposed quite hardy. Looks like typical *V. 'Pragense'* to me. In January 2006, while visiting Piedmont Carolina Nursery near Greensboro, North Carolina, I looked over a number of 'Decker' and simply could not tell an iota of difference between this and 'Pragense'.

Viburnum sargentii Koehne (*V. opulus* var. *sargentii* (Koehne) Tak. in GRIN) — Sargent Viburnum (vī-bēr'num sār-gen'tē-ī)

LEAVES: Opposite, simple, similar to *V. opulus* but of thicker texture and often larger, 2 to 5" long, the upper ones usually with much elongated entire middle lobe and short spreading lateral lobes, sometimes oblong-lanceolate and without lobes, medium to dark green and glabrous above, lighter beneath and slightly pubescent below; petiole— 3/4 to 1 3/4" long with large disk-like glands, pinkish or reddish in color.

BUDS: Oblong or flask-shaped, 1/3" long, mostly appressed, scurfy, scales closely valvate or connate as a closed sac, green to red in color.

STEM: Straw-colored to brownish, often of polished appearance, thickish for a viburnum stem, about 1/3" diameter, glabrous, somewhat corky compared to *V. opulus* and *V. trilobum*.

SIZE: 12 to 15' high and 12 to 15' in width.

HARDINESS: Zone 3 to 7.

HABIT: Multi-stemmed upright-rounded to rounded shrub of relatively coarse texture; somewhat similar to *V. opulus* and *V. trilobum* but not as handsome.

RATE: Medium, I noticed a specimen at Purdue's Horticultural Park which exhibited extreme vigor; likewise venerable specimen in Littlefield Garden, University of Maine.

TEXTURE: Would have to be rated coarse in all seasons.

LEAF COLOR: New spring growth often bronze-purple; lustrous medium to dark green in summer; often assuming yellowish to reddish tones in fall.

FLOWERS: White, stinky, several degrees more than *V. opulus*, borne in flat-topped, 3 to 4" diameter cymes on 1 to 2" long stalks; sterile outer flowers about 1" or slightly greater in diameter; the anthers are sometimes purple (usually not) and differ from the yellow anthers of *V. opulus*, May.

FRUIT: Scarlet, 1/3 to 1/2" long, globose, shiny berry-like drupe; effective in August through October.

CULTURE: Similar to other viburnums especially *V. opulus*; more aphid-resistant than *V. opulus*; observed slight viburnum beetle feeding; definitely not heat tolerant and is best suited to colder climates.

DISEASES AND INSECTS: None particularly serious.

LANDSCAPE VALUE: Interesting species but a degree too coarse in comparison to other viburnums with similar ornamental characters; the fruits are excellent and of a bright, translucent red, lasting well into winter.

CULTIVARS:

'Chiquita'—A compact, 5 to 6' high and wide selection. Flowers and fruits similar to the species. Medium green leaves turn yellow in autumn. Introduced by McKay Nursery, Waterloo, Wisconsin.

'Flavum' (f. *flavum* Rehd., 'Fructolutea')—Yellow anthers and golden-yellow translucent fruits. Wyman had an interesting anecdote concerning a trial he conducted growing seedlings from the yellow-fruited form. He noted that many seedlings showed yellowish leaf petioles and others reddish. The seedlings with yellowish petioles turned yellowish green in fall; those with reddish petioles colored red. Obviously the fruits will follow the same trends exhibited in petiole color.

forma *lutescens*—Presumably a reference to the yellow fruit color, but it could be the foliage color that is meant; could be an alternative name for forma *flavum*.

'Onondaga'—An Egolf/U.S. National Arboretum introduction distinguished by the velvety, fine-textured, dark maroon young foliage that maintains a maroon tinge when mature. Leaves are smaller than species, still with the long central lobe. Flower buds are maroon-red, opening creamy-white with a trace of pink, in 2 to 4" wide, flat-topped cymes, with 10 to 17 outer, 1 1/4 to 1 3/4" wide, sterile florets. The red fruits are sparsely produced. Usually forms a globose shrub 6' high and wide but will grow larger. I have seen 8 to 10' high specimens and, at Hillier Arboretum, I experienced a 12' high plant on July 1, 1999. Typically, 'Onondaga' is more upright in habit than the species. Introduced in 1966.

'Puberlosum'—Smaller flowers and pubescent parts. Taxonomically, I don't know whether this designation is justified.

'Puberulum'—Looks suspiciously like 'Puberlosum'. A 15' by 15' foot plant with terrible leaf spot grew at Hillier in 1999. I examined herbarium specimens of both and saw no differences.

forma *sterile*—A semi-snowball form that, from the photo I witnessed, is striking.

'Susquehanna'—An Egolf/U.S. National Arboretum introduction from 1966 best described as a select *V. sargentii* with a heavy-branched, corky trunk; coriaceous, dark green foliage; abundant flowers and fruits; and upright growth habit. Leaves, up to 5 1/2" long, central lobe more than half the length of the leaf, not as pubescent as species, 'Onondaga', 'Puberlosum', and 'Puberulum'. New growth emerges green in April, a reasonable way to separate it from 'Onondaga'. Appeared as a seedling in a population of 209 raised from seed obtained from Matsu, Hondo, Japan. It becomes a large shrub, 12 to 15' high, approximating the species in size. I have seen it in fruit, and the effect is striking. Flowers are stinky. Probably too large for the average landscape but good for parks, campuses, and large areas. A 15' by 15' specimen noted at Hillier, May 31, 2006.

PROPAGATION: Easily propagated by cuttings. Seed probably possesses a double dormancy similar to *V. opulus* and a warm stratification of 60 to 90 days followed by cold for 30 to 60 days should suffice.

ADDITIONAL NOTES: Interesting paper in *J. Japanese Bot.* 69(1):31–32 (1994), that proposes *V. sargentii* as the Asiatic variety of *V. opulus*, i.e., *V. opulus* var. *sargentii*; var. *opulus* is the typical form that occurs in the west of the distribution.

NATIVE HABITAT: Northeastern Asia. Introduced 1892.

Viburnum setigerum Hance. — Tea Viburnum

(vī-bēr'num se-tij'ēr-um)

LEAVES: Opposite, simple, ovate-lanceolate, 3 to 6" long, 1 1/4 to 2 1/2" wide, acuminate, rounded at base, remotely denticulate, flat, soft blue-green to dark green above, glabrous except silky hairs on the veins beneath with 6 to 9 pairs of veins; petiole—1/2 to 1" long, glabrous or hairy like midrib.

BUDS: Imbricate, terminal—green with red; lateral—green with red tip, large and glabrous, very prominent, usually with 3 to 5 visible scales.

STEM: Glabrous, smooth, gray and usually stout.

SIZE: 8 to 12' tall, 2/3's that in width.

HARDINESS: Zone 5 to 7(8), have seen plants in Zone 8, essentially flattened at Orono, ME.

HABIT: Upright, multi-stemmed, often leggy at the base, but if used properly the leggy character is minimized, delicate foliage with slight nodding tendency.

RATE: Slow, possibly medium.

TEXTURE: Medium-coarse in foliage; coarse in winter.

LEAF COLOR: Flat, soft blue-green foliage in summer; fall color is inconsistent but can develop reddish purple.

FLOWERS: White, mid to late May, borne in 1 to 2" diameter, 5-rayed, flat-topped cymes on 1/2 to 1" long peduncles; not unpleasant; limitedly ornamental.

FRUIT: Drupe, egg-shaped, 1/3 to 1/2" long, bright red, September–October into late fall, very effective, possibly the most handsome fruiter among the viburnums, always one of my favorites for fruit effect.

CULTURE: Similar to other viburnums.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Shrub border situations because of leggy habit, fruit is outstanding; derives its name from the fact that the leaves were used for making tea.

CULTIVARS:

'Auranticum'—Orange-fruited form, handsome in fruit but like the species; often leggy; Arnold Arboretum introduction from seed Wilson collected in Hubei, China in 1907.

PROPAGATION: I have rooted this species from leafy cuttings collected as late as September.

ADDITIONAL NOTES: I have seen branches so heavily laden with fruit that they literally arched and almost touched the ground. Unfortunately, this is not a very popular viburnum but when used correctly it can hold its own against any, especially in fall.

NATIVE HABITAT: Central and western China. Introduced 1901.

Viburnum sieboldii Miq. — Siebold Viburnum

(vī-bēr'num sē-bōl'dē-ī)

LEAVES: Opposite, simple, elliptic or obovate to oblong, 2 to 5"(6") long, 1 1/2 to 3" wide, acute, broad-cuneate, coarsely crenate-serrate, lustrous dark green and glabrous above, stellate pubescent chiefly on the veins beneath, with 7 to 10 pairs of prominent impressed veins; petiole—1/4 to 3/4" long; leaves when crushed emitting a fetid odor.

BUDS: Flower large, valvate, angled, 4-sided, gray-green-brown, slightly pubescent.

STEM: Slightly pubescent, stout, leaf scars connecting around the stem, usually grayish in color.

SIZE: 15 to 20' in height, spread 10 to 15', can reach 30' in height.

HARDINESS: Zone 4 to 7(8); growing successfully at Minnesota Landscape Arboretum, also at Orono, ME.

HABIT: Large shrub or small tree of open habit with stiff, stout, rigid branches.

RATE: Medium, possibly fast under ideal growing conditions.

TEXTURE: A rugged, handsome coarseness in summer and winter.

LEAF COLOR: Lustrous dark green, extremely clean looking foliage, very fetid (green peppers) if crushed, fall color is usually nonexistent (green); however, various authors indicated red-purple a possibility and I saw one specimen at the University of Maine with an ashy purple color; tends to hold leaves late often into November.

FLOWERS: Creamy white, late May, borne in 3 to 6" diameter, long-stalked, cymose-paniculate clusters; excellent effect because flowers are borne in great abundance literally masking the bright green foliage.

FRUIT: Drupe, oval, 1/3 to 1/2" long, rose-red to red changing to black, effective for weeks in August through early October, birds seem to devour the fruits; however, the inflorescences are handsome rose-red and remain effective for two to four weeks after the fruits are gone; the fruit must be seen to be fully appreciated and the result is usually love at first sight.

CULTURE: Transplants well, adaptable, prefers moist, well-drained soils; tolerates partially shaded situations; definitely needs sufficient moisture as leaf scorch will develop under dry soil conditions; pH adaptable.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: Specimen, against large buildings, blank walls, groupings; open habit, excellent foliage, flowers and fruits make it worthy of consideration for many landscape situations.

CULTIVARS:

Ironclad™ ('KLMfour')—From Roy Klehm at Beaver Creek Nursery. This selection was dubbed Ironclad™ when it was the only survivor of a seedling planting. Listed as a heavy-flowering form with creamy white cymes; clean, rugose, shiny green summer foliage; green-burgundy fall color; and red fruits that age black. Matures 15' high by 12' wide. True Zone 4.

varieties *longifolium* Satake and *reticulatum* (Yamagita) Sugimoto (f. *reticulatum* (Rehd.) Rehd. in GRIN)—Listed by Kenyon (2001). I have not observed them.

var. *obovatifolium* (Yamagita) Sugimoto—Obovate to broad-rounded, serrate leaves to 10" long. Every plant I'd ever witnessed at three gardens in England had smaller leaves; then on May 27, 2006, I experienced a 12' by 10' foot plant with obovate, 10" leaves at Wakehurst Place. Fit the botanical description like an old shoe. Good-looking plant but unique only by virtue of the foliage. Found on the Sea of Japan side of Honshu.

'Seneca'—Resulted from a self-pollination of *V. sieboldii*. The plant was selected for the abundant, large, pendulant inflorescences of firm red fruits on red pedicels, which persist on the plant up to three months before turning black and falling. The massive, creamy white panicles are produced in May-early June as the young foliage unfolds. The panicles are supported on stout, spreading branches that are picturesque in all seasons. The multi-colored clusters of orange-red ripening to blood-red fruits are spectacularly displayed above the coriaceous, green foliage. Birds normally eat the fruits of *V. sieboldii* before it has matured; the fruits of 'Seneca', however, are very firm and are not devoured by birds even when fully ripe (countering this claim, Lanny Rawdon, the former Arborvillage, Holt, Missouri, reports Midwest birds love 'Seneca' fruits). 'Seneca' is tree-like and will undoubtedly equal plants of the species in size; it can be as much as 30' high with a gnarled trunk and has attained a width of 13 1/2'. This cultivar can also be trained with several branches from the base and kept as a large spreading shrub. An Egolf/U.S. National Arboretum introduction in 1966.

'Wavecrest'—Vigorous grower with brick-red fall color and large leaves and flowers. From Eugene W. Coffman, Ridge Road Nursery, Bellevue, Iowa, who received a seedling from Robert Tomayer, Wavecrest Nursery, Fennville, Michigan, with larger, thicker leaves. In a letter to me, Coffman reports the abundant fruits are orange, and the pedicels bright scarlet; he describes fall color as barn-red. His original plant was 7 to 8' high and 4' across after five years in Zone 4.

PROPAGATION: Cuttings, softwood—root easily.

NATIVE HABITAT: Japan. Cultivated 1880.

Viburnum suspensum Lindl. — Sandankwa Viburnum
(vī-bēr'num sus-pen'sum)

LEAVES: Opposite, simple, evergreen, ovate to oval, 2 to 5" long, 1 1/2 to 3" wide, pointed, rounded or broadly wedge-shaped, toothed in the upper two-third's or scarcely at all, leathery lustrous green, glabrous, 4 to 5 prominent vein pairs; petiole—1/4 to 1/2" long.

Viburnum suspensum is a 6 to 12' high evergreen shrub that is used in the Coastal Plain and frequently seen in Florida gardens. The white, faintly tinged pink, fragrant flowers occur in a 2 1/2 to 4" long and wide, corymbose panicle in February–March (Zone 7). The globose fruits are red maturing to black. I have seen it used for hedges in Georgia and Florida. It appears to prefer a hot dry climate and also seems well-suited to sandy soils. Site in full sun to moderate shade. I see the species everywhere in Florida all the way to Key West where it is used for screens, specimens and the ubiquitous hedge. Interestingly, sizeable plants were killed to the ground or outright on the Georgia coast at 11°F. Bob McCartney, Woodlanders, Aiken, SC told me there are immense specimens in Florida. Ryukyus. Introduced 1850. Zone (8)9 to 11.

Viburnum tinus L. — Laurustinus
(vī-bēr'num tī'nus)

LEAVES: Opposite, simple, evergreen, narrowly ovate to oblong, 1 1/2 to 4" long, 3/4 to 1 1/2" wide, entire, lustrous dark green above, paler beneath, axillary tufts below; petiole—1/3 to 3/4" long, usually pubescent.

Viburnum tinus is a fine upright-rounded evergreen species that reaches 6 to 12' in height and usually less in spread. The lustrous dark green leaves are handsome throughout the year. The pink-budded, 2 to 4" diameter flowers open to white and often flower in January–February (March) in the South. Species is reported to be self incompatible so another seedling or clone must be in proximity to induce good fruit set. The flowers are followed by ovoid, metallic blue fruits that mature blue-black to black. It is an excellent plant for screening, hedging and withstands considerable shade as well as salt spray. It is hardy to 0°F once established and appears to be insect and disease-free.

CULTIVARS:

'Bewley's Variegated'—Significantly variegated pale cream to soft yellow leaves, dense bushy habit, 6 to 7' high and wide. A small plant in our shop was impressive. Larger plants I observed in England are similar to 'Variegatum'. Less cold hardy than the species. Flower buds are pink, opening white.

'Clyne Castle'—Large, glossy leaves and improved hardiness.

'Compactum'—Will grow one-half to three quarters the size of the species and has slightly smaller leaves than the species. A respectable specimen grew in the White Garden, JC Raulston Arboretum, for many years.

'Eve Price'—A compact form with smaller leaves than the species and attractive buds and pink-tinged flowers. Plant at Hillier was 15' by 10' with a strongly upright vase shape.

'French White'—A strong-growing form with large, white flower heads. Eighteen feet by 10' at Hillier in 1999.

'Froebelii'—Compact with light green leaves and snow-white flowers.

'Gwenllian'—Grows 10' high and wide. Leaves are dark green. Flowers rich pink in bud, opening blush.

'Isreal'—Large leaves and waxy, clear white flowers.

'Little Bognor'—A compact selection that appeared to be the real deal when observed in a container at Wyevalle Garden Center in England. Have not observed the plant since that 1999 sighting.

'Lucidum'—Larger in all its parts. Extremely lustrous dark green leaves, full and dense to ground, 12' high and wide at Hillier in 1999.

'Lucidum Variegatum'—Marble-like swirled green and white foliage but is unstable and will revert to green.

'Nutsy'—Described as having deep green leaves, pink buds opening to pink-white flowers in late winter–early spring, and metallic deep blue fruits. Who named this?

'Pink Prelude'—Produces white flowers that age pink, 10' by 12', dense, rounded with finer leaf texture.

'Purpureum'—Purple young leaves that mature green, tinted red.

Subspecies *rigidum* (Vent.) P. Silva—The robust, large-leaf, quite hairy variation from the Canary Islands.

Distinguished from *V. tinus* by the larger (up to 4" long), dull green, hairy leaves and more open habit.

Also treated as a species, *V. rigidum* Vent.

'Robustum'—Larger in its upright dense habit (15') and leaf (4"), has deep green leaves, and blush-white flowers.

'Spectrum' ('Pyramidale')—Erect, narrow-conical in habit. Witnessed an 8' by 8' plant, dense, rounded, healthy foliage, fine to medium texture at Hillier, July 1, 1999.

'Spirit'—Looks good in leaf with red-purple flower buds, opening white. More compact growth habit and earlier to flower than 'Spring Bouquet'. Supposedly grows *only* to 5' high, but is already larger than this in several southeastern gardens.

'Spring Bouquet'—May be the same as 'Compactum' and offers dark red flower buds that open to white on a 5 to 6' high and wide compact plant.

'Variegatum'—A handsome clone with conspicuous creamy yellow variegation. Not as cold hardy as the species. A 6' by 5' dense plant grew at Hillier in 1999.

This is a variable species in degree of pubescence, leaf size, etc. It is not common in the South (becoming more so) but does make a handsome evergreen shrub. It can be used for screening, hedging, and massing. I noticed the plant was frequently used in England. I have observed numerous plants, especially in English gardens. It is a serviceable evergreen shrub for Mediterranean climates or where winter temperatures seldom drop below 10°F. Over my 30 years in Athens, GA, I have watched a 7' high specimen disappear to its root tips. The University grounds department tried several plants of 'Spring Bouquet' in a protected area only to have them succumb to the vagaries of a southern winter. I do not believe the plant hardens off early enough in fall to avoid the early fall freezes. In Washington, GA, 40 miles southeast of Athens, I discovered two 8 to 10' specimens that survived the mid-1980's and 1994 cold. Perhaps 5°F difference between Athens and Washington. Observed thriving plants in the Chapel Hill, NC area. A plant in our Chapel Hill garden looks great with pink flower buds coming out of winter but has been injured by late spring frosts. Southern Europe, primarily in the Mediterranean region, northern Africa. Cultivated since 16th century in England. Zone (8)9 to 10.

Viburnum trilobum Marsh. (*V. opulus* var. *americanum* Ait. in GRIN) — American Cranberrybush Viburnum

(vī-bēr'num trī-lō'bum)

LEAVES: Opposite, simple, 3-lobed, broad-ovate, 2 to 5" long, lobes acuminate, rounded or truncate at base, coarsely dentate, sometimes the middle lobe elongated and entire, dark green and usually lustrous above, pilose on the veins beneath, or nearly glabrous; petiole—1/2 to 1" long with shallow groove and small dome-shaped, usually stalked glands.

BUDS: Similar to *V. opulus*, sometimes sticky, green-reddish and smooth, with 2 connate outer scales.

STEM: Gray-brown, glabrous, with a waxy appearance.

SIZE: 8 to 12' in height, spread 8 to 12'.

HARDINESS: Zone 2 to 7, can grow in 8 but not well-adapted to the heat; have yet to observe a quality plant in Zone 7.

HABIT: Similar to *V. opulus*, round-topped and fairly dense.

RATE: Medium.

TEXTURE: Medium in foliage; medium to coarse in winter.

LEAF COLOR: Lustrous medium to dark green changing to yellow through red-purple in fall; new growth has a reddish tinge.

FLOWERS: White, similar to *V. opulus*, non-offensive floral odor, mid to late May, 3 to 4 1/2" diameter, flat-topped cymes; extremely handsome, possibly better than *V. opulus* but the plant is not as available through nurseries.

FRUIT: Drupe, nearly globose, 1/3" long, bright red, early September through fall into February, holds better than *V. opulus*, edible, used for preserves and jellies.

CULTURE: Native species, transplants well; prefers good, well-drained, moist soil; sun or partial shade; should be more adaptable than *V. opulus* due to wide native range, however, limitedly planted; in Maine I see it growing along the roadsides in moist ditch banks, wet swampy areas.

DISEASES AND INSECTS: A stem blight can kill plant in warm humid states; borers.

LANDSCAPE VALUE: Excellent plant for screening and informal hedging; like *V. opulus* it becomes too large for the small landscape; I have seen it used to define boundaries between houses in subdivisions and it really

affords a good privacy screen and at the same time offers excellent flower, fruit and foliage; if subjected to excessive water stress it declines rapidly and makes a rather poor specimen.

CULTIVARS:

'Andrews', 'Hahs', and 'Wentworth'—Have been selected for larger fruits. The story goes deeper than that, for in the early 1900s A. E. Morgan assembled over 3,000 seedlings from North America in Lee, Massachusetts. In 1921, the USDA took over the study and released the three just mentioned in 1922. They are early, mid, and late ripening, respectively, and were selected for edibility. I have observed 'Wentworth', and it is beautiful as the fruits pass from a yellow-red to bright red but, in my mind, is no better than other plants I have seen in various locations. It may have the best red fall color. 'Hahs' has large fruits and is popular in the Chicago region. 'Hahs' matures at a smaller size than the species, 6 to 8' high and wide, and produces 2 to 4" wide cymes and attractive, neat, dark green foliage. Noted a 6', compact specimen with more abundant fruit than 'Wentworth' at the Minnesota Landscape Arboretum on July 20, 2005. Listed as hardy to Zone 2. 'Wentworth', of the three, is the most available in commerce and grows 10 to 12' high and wide. Large, wild, loose, open, 15' by 15' specimen at Hillier, July 2, 1999.

'Alfredo'—Similar to 'Compactum' but with a denser, broader habit, 5 to 6' high and wide, good summer foliage, and excellent red fall color. Supposedly quite aphid resistant. Selected by Alfredo Garcia, Bailey Nurseries, St. Paul, Minnesota. Flower and fruit set are sparse. Unfortunately, I have read literature that said fruit set was good.

'Bailey Compact'—Another selection from Bailey Nurseries, with compact habit, 5 to 6' high and wide, deep red fall foliage, and moderate fruit.

'Compactum'—An excellent compact, dwarf form with good flowering and fruiting habit. The stems are much more slender and uniformly upright-spreading than its counterpart, *V. opulus* 'Compactum', and it grows about half the size of the species (6'). Fall color is not particularly good and is usually yellow at best. The entire taxonomy of this group is rather confusing, and I am not sure I can "unconfuse" it. True 'Compactum' is alternately listed as virtually sterile and heavy flowering and fruiting. In my Illinois garden, 'Compactum' grew with passion and flowered and fruited without any significant fall color. I have a suspicion that lack of fruit set on 'Compactum' may be the result of the lack of a suitable cross-pollinator.

'Garry Pink'—Pink flowers in cool, moist weather; if hot and dry, flowers are white. Discovered in 1962 in Fort Garry, Manitoba, Canada.

'Jewell Box'—Dwarf, compact habit described as resembling a cushion mum, 18" high by 24 to 30" wide. New foliage emerges red, then dark green, with a burgundy fall color. Flowering is virtually nil, but a few inflorescences were observed. Considered less susceptible to leaf spot than *V. opulus* 'Nanum'. Introduced by John Lindmeyer, formerly with Jewell Nursery, Wisconsin.

Leelanau Germplasm—From seed collected in 1981 in Leelanau County, Michigan, is offered by Rose Lake Plant Material Center, East Lansing, Michigan.

'Leonard's Dwarf'—I have seen placed under *V. opulus*. It is vigorous and compact with broom-like branches. How different it is from other compact forms, I do not know.

'Manito' ('Manitou Pembina' by Dawes Arboretum, Newark, Ohio)—Selected for large fruit size and named in 1947. Original plant grew by Lake Manitoba.

'Phillips'—Deep wine-red fruits. This form flowers and fruits abundantly and free of the odor and flavor of the species, making it useful for jelly. Grows 8 to 10' high and wide on an upright habit with clean foliage. Zone 2 hardy. Introduced in 1956 by E. M. Meader, University of New Hampshire, Durham, who introduced many useful plants.

Redwing™ ('J. N. Select')—Produces a strong red flush of new growth and offers a neat, dense habit. The dark green leaves turn bright red in autumn. Three to 4" wide, white inflorescences and bright red, persistent fruits are also colorful. Matures 8 to 12' high and wide. Viburnum crown borer can be a problem. Selected by Michael Yanny in 1983 and introduced by Johnson's Nursery, Menomonee Falls, Wisconsin.

'Spring Green Compact'—More refined than the species in flower, foliage, and fruit. It produces excellent red fruits and orange-red fall color on a 3 to 4' high shrub.

'Spring Red Compact'—New reddish growth that turns green at maturity, good orange-red fall color, and a limited fruit set. It is somewhat upright in growth habit, maturing 3 to 5' high.

PROPAGATION: Seeds require the normal warm/cold routine but cuttings are easy to root; softwood cuttings in late July, 1,000 ppm IBA-quick dip, peat:perlite, mist, rooted 100% in 6 weeks.

ADDITIONAL NOTES: I have refrained from giving recipes primarily because I like Snicker's bars better than ornamental plant concoctions. I relent here and present what sounds like a recipe for a fine jam. Simmer cleaned fruit for 10 minutes in 1/3 its weight of water; put through a sieve, use a little more water to remove pulp from seeds; add sugar to equal weight of cleaned fruit; boil to 222°F; pour into jars and immediately seal; yields beautiful ruby jam with distinctive flavor. Actually part of native fruit improvement program in Saskatchewan, see *HortScience* 27(8):866, 947 (1992).

NATIVE HABITAT: New Brunswick to British Columbia, south to New York, Michigan, South Dakota and Oregon. Introduced 1812.

Vinca minor L. — Common Periwinkle, Lesser Periwinkle

(ving'ka mī 'nôr)

FAMILY: Apocynaceae

LEAVES: Opposite, simple, evergreen, elliptic, oblong or elliptic-ovate, 1/2 to 1 1/2" long, 1/2 to 3/4" wide, acutish or obtuse, rounded or cuneate, entire, lustrous medium to perhaps dark green above, lighter green beneath; petiole—short, 1/2 to 1 1/4" long, exuding a milky juice when broken.

STEM: Shining green, glabrous.

SIZE: 3 to 6"(8") high, ground-hugging plant.

HARDINESS: Zone 4 to 8(9), can be grown further north when protected by snow.

HABIT: Low growing, prostrate, mat-forming evergreen ground cover, spreading indefinitely, flowers borne on erect shoots.

RATE: Medium to fast; in a loose, organic, well-drained soil will fill in very fast.

TEXTURE: Medium-fine in all seasons.

LEAF COLOR: New growth emerges early, often March in Athens and is a handsome yellow-green maturing to lustrous green in summer, often losing some of the sheen in winter.

FLOWERS: Perfect, lilac-blue, blue-violet, 1" diameter, March–April, borne solitary on 1/2 to 1 1/4" long pedicels; very attractive in flower and sporadically flowering over a long period, monitored flowering for the entire month of March.

FRUIT: Follicle, not ornamental, seldom set on cultivated plants.

CULTURE: Transplant from pots or as a bare root plant into moist, well-drained soil abundantly supplemented with organic matter; supposedly does equally well in full sun or shade, but I have seen considerable leaf discoloration (yellowing and browning) in winter and summer under full sun conditions; can tolerate poor soils but will not develop and fill in as fast.

DISEASES AND INSECTS: Blight, canker and dieback, *Colletrichum gloeosporioides* causes leaf spots and stem lesions (see *Plant Disease* 79(1):83 (1995)), leaf spots, cucumber mosaic virus, and root rot; the canker and dieback (*Phomaexigua* var. *exigua*) disease has been a significant problem; the shoots become dark brown, wilt, and die back to the surface of the soil; also, *Verticillium albo-atrum* was reported on *Vinca major* in California (see *Plant Disease* 72(12):1077 (1988)); *HortScience* 30(3):554–557 (1995) discusses fungicidal control of foliar diseases caused by *Colletotrichum* sp. and *Phoma* sp.LANDSCAPE VALUE: Excellent ground cover in spite of problems; the dainty blue flowers are handsome as is the lustrous foliage; plant on 1' centers; makes its best growth in shade and here can form large carpets under the leafy canopy; the new growth emerges a rich spring green and the flowers appear at the same time; flowers over a long period; never really spectacular unless viewed close up, too often large seas of the plant are used in dense shade; I have seen mixed plantings with daffodils and other bulbs that bring the carpet to life in spring; I suspect that *Colchicum* species would do nicely and perhaps even *Lycoris radiata* in more southerly locations; somewhat of an ambitious rogue and may become invasive; certainly forms a great green carpet essentially exclusive of herbaceous flora.

CULTIVARS: Noted over 30 names in RHS Plant Finder 2007–2008.

'Alba'—White-flowering form representing a nice change from the lilac-blue of the species; 'Alba Plena' ('Albo Plena' is listed) with double, white flowers is known.

'Alba Variegata'—White flowers and leaves edged with light yellow; old cultivar.

'Argenteovariegata'—Blue flowers and leaves margined with white; leaves shorter and broader than typical species.

'Atropurpurea'—Deep plum-purple flowers, rather handsome form, flowers are large and have good substance; first recorded in 1826.

'Aureovariegata'—Blue flowers and leaves with yellow blotches and stripes.

'Azurea Flore Pleno'—Sky-blue, double flowers; dark green leaves; 6 to 8".

'Blue & Gold'—Bright yellow-margined leaves; blue flowers.

'Bowles' ('Bowles Variety')—See 'La Grave'.

'Bowles White'—Flowers flushed pink in bud, white when open, large.

'Burgundy'—With burgundy flowers, saw at Van Dusen Botanical Garden, Vancouver.

'Dart's Blue'—Sport of Bowles with blue flowers, canker resistant.

'Emily' ('Emily Joy')—Large, white flowers; glossy green leaves; compact, 8 to 10".

'Fieldstone Splash'—Dark outer margin, chartreuse-yellow center, glowing venation; blue flowers; see www.fieldstone-garden.com.

'Florepleno'—Double, purple-blue flowers.

'Gertrude Jekyll' ('Miss Jekyll')—A form with glistening white flowers, quite attractive, flowers freely borne; flowers and foliage smaller than typical.

- 'Giant Steps' (PP 16,651)—Larger leaf, significantly heavier foliage substance; periwinkle-blue flowers; branch sport of 'Bowles' discovered by Tom Foley, Jr. in Vacaville, CA; Hines Nursery introduction.
- 'Gold Heart'—Irregular splashes of golden yellow in the center of the leaves.
- 'Golden'—Yellow-margined leaves and white flowers.
- 'Golden Bowles'—Young foliage light green with an irregular margin of gold; white flowers.
- 'Golden Vein'—Bright green leaves with golden center radiating out along the veins.
- 'Green Carpet' ('Grüner Teppich')—Apparently a non-flowering form of *V. minor* with luxuriant rich green leaves that are larger than the type.
- 'Haskell'—Deep green leaf margins, light yellow centers.
- 'Honeydew'—Chartreuse foliage; pale blue flowers.
- 'Illumination' (PP 12,132)—Bright yellow center grading to lighter cream-yellow with a green margin; flowers blue; extensive promotion and hype but . . . totally unstable and reverts to green, witnessed entire planting that reverted to green in Zone 7, was told it did not revert in North, I don't believe it.
- 'La Grave' ('Bowles', 'Bowles Variety')—Large, up to 1 1/2" diameter, lavender-blue (deep mauve) flowers; this is also the same, according to the literature, as 'Bowles Variety' which is listed as having larger azure-blue flowers, vigorous growth habit but more clumpy rather than spreading like the species; I received 'La Grave' from Dr. Raulston and indeed it was superior in size and color, the petals having more substance than the typical species type; the 'Bowles Variety' I have seen in commerce is not the same as 'La Grave' but the plant does not always match up with the name; true 'La Grave' is a more handsome plant and is worth pursuing; collected by E.A. Bowles in the 1920's in the churchyard of La Grave in the Dauphine, France.
- 'Multiplex'—Plum-purple, double flowers; dark green foliage.
- 'Myrtle Bowles'—Deep purple flowers sporadically produced in summer; glossy green leaves.
- 'Onland Blue'—Form with large light violet-blue flowers, narrower in the petals than 'La Grave', see *The Garden* 109:426–429 (1984) for a Wisley Garden "Trial of *Vinca* cultivars."
- 'Persian Carpet'—Large gray-green leaves edged white; low-growing; described as non-flowering.
- 'Ralph Shugert'—Uniform creamy white to white margins on dark green leaves; more regular marginal variegation and darker green; smaller leaves than 'Argenteovariegata', similar to 'Bowles Variety' in floral characteristics; introduced by David MacKenzie, Spring Lake, MI.
- 'Rosea'—Flowers violet-pink; smaller leaves.
- 'Rosea Plena'—Flowers violet-pink, double.
- 'Royal Blue'—Deeper blue flowers, witnessed at Van Dusen Botanical Garden.
- 'Shademaster'—A dense, evergreen, ground cover with purple flowers; a Princeton Nursery introduction.
- 'Silver Service'—Leaves edged gray-green; double blue flowers.
- 'Sterling Silver'—Pretty, cream-variegated leaf form with pale violet-blue flowers; handsome selection, was popular in New England.
- 'Summersnow' (PP 8,170)—Foliage is medium green, light green, white with occasional yellow blotches on each leaf; a branch sport of 'Bowles'.
- 'Sunny Skies' (PP 13,466)—Foliage with varying shades of golden yellow-green and dark green; a branch sport of 'Bowles'.
- 'Temptation'—Small, double, lavender flowers; shiny dark green foliage; 2 to 4".
- 'Valley Glow'—New growth golden; white flowers.
- 'Wine'—Wine red flowers.
- 'Wojo's Jem' (PP 11,809)—Green margins, ivory centers; I doubt stability.

PROPAGATION: Fresh seeds of 'Gertrude Jekyll' were give a 24 hour soak in Gibberellic acid (GA) at 0 or 1,000 ppm and/or stratified for 0, 30, 60, 90 days; 1,000 ppm GA, plus 90 days cold stratification resulted in 70% germination in 30 days; neither GA nor cold alone induced germination. Division, also extremely easy from cuttings.

NATIVE HABITAT: Europe and western Asia, cultivated since ancient times; escaped from cultivation.

RELATED SPECIES:

***Vinca major* L.** — Large Periwinkle, Greater Periwinkle
(ving'ka mā'jôr)

LEAVES: Opposite, simple, evergreen, ovate to broad ovate to lanceolate, 1 to 3"(3 1/2") long, half to two-third's as wide, acute or obtusish, often nearly cordate, entire but often with marginal ciliate hairs, lustrous dark green and glabrous above, lighter beneath; petiole—1/3 to 1/2" long.

Vinca major, Large Periwinkle, is essentially a large carbon copy of the *Vinca minor*. The plant averages between 12 to 18" high. It flowers well in full sun and the flowers often occur sporadically over the growing season. Flowers in March–April in Athens. *Vinca major* prefers moist, well-drained soils and shade. Makes a good ground cover in dense shade. 'Variegata' ('Elegantissima') has leaves that are blotched and margined

irregularly with creamy white markings.

'Variegata' is as hardy and vigorous as the species and the flowers are similar.

Have seen 'Variegata' used at a residence in Columbus, OH with some success. Near the foundation it overwintered in good condition but was obliterated 3 to 4' from the foundation.

Should be cut back in spring. Used for window boxes, containers and urns; cascades gracefully over their edges. In an earlier edition, I commented that this species was more drought resistant than *V. minor*.

After observing both species during the two hottest and driest back-to-back summers on record in the south, I give the adaptability nod to *V. minor*. *Vinca major* showed pronounced wilting.

Have also seen a narrow-petaled, deep purple form in England termed 'Oxyloba'

(var. *oxyloba*). 'Aureomaculata' has a central blotch of yellow-green and arose as a chimera on 'Variegata'. 'Jason Hill' has deeper violet-blue flowers with a white eye. 'Major' has dark green leaves, blue-violet flowers. 'Reticulata', with yellow veining when young, later green is known. 'Surrey Marble' as observed in England, has green-yellow center, green margins; also listed as 'Maculata', perhaps 'Aureomaculata'. Extremely vigorous and will quickly colonize real estate. Planted in the shade garden at the University's Botanical Garden and blanketed the site like no other groundcover I know. Scary! France, Italy, former Yugoslavia. Cultivated 1789. Zone 6 to 9.

'Variegata'

Vitex negundo L. — Chastetree

(vī'teks nē-gun'dō)

FAMILY: Verbenaceae

LEAVES: Opposite, compound palmate, leaflets usually 5, sometimes 3 to 7, 1 1/4 to 4" (5") long, sessile or short-petioled, elliptic-ovate to lanceolate, entire or serrate, grayish green, tomentulose beneath; petiole—3/4 to 2" long.

BUDS: Superposed, sessile or the upper commonly developing the first season, subglobose, the 1 or 2 pairs of leaf rudiments or scales concealed in pubescence.

STEM: Compressed at nodes, quadrangular with obtuse or flattened angles, rather slender; pith relatively large, more or less angled, white, continuous and homogeneous; leaf scars U-shaped, rather small, low; the surface usually torn and the solitary bundle trace indistinct.

SIZE: Difficult to predict in the North since the plants are often frozen to the ground; the height in one growing season might be 3 to 5' but if no damage is done, over the years the plant may grow 10 to 15'; plants at the JC Raulston Arboretum were over 20' high.

HARDINESS: Zone 6, often listed as 5 but shakily so, does well in southern states, into Zone 8; considerable *Vitex agnus-castus* utilized in coastal North Carolina landscapes; witnessed more than expected in Wilmington, Wrightsville Beach area.

HABIT: Not a bad looking plant in leaf; develops a loosely branched, airy, open outline, vase-shaped habit with cloud-like airy foliage canopy, can become ratty with time, requires pruning.

RATE: Fast.

TEXTURE: Medium-fine in leaf; medium-coarse in winter; leaflets out late.

LEAF COLOR: Grayish green cast in summer; nothing to speak of in the way of fall color; freeze renders leaves crispy.

FLOWERS: Small, blue-purple, lilac or lavender, in loose clusters forming slender spikes collected into terminal 5 to 8" long panicles; effective in July–August (early to mid June in Athens); flowers on new growth of the season.

FRUIT: A small drupe of no consequence, persists, if removed new growth often ensues and additional flowers are produced.

CULTURE: Transplant as a container plant into loose, moist, well-drained soil; full sun; prefer hot weather; well-drained situation definitely aids in reducing winter injury; if pruning is necessary, cut the plant to within 6 to 12" of the ground in spring or back to live wood on old plants.

DISEASES AND INSECTS: Several leaf spots and a root rot have been reported but are not serious; in nursery settings, particularly with overhead watering, leaf spot can disfigure and induce premature defoliation.

LANDSCAPE VALUE: Possibly a plant for the shrub border; should almost be treated as an herbaceous perennial in the North; interesting foliage texture and late season flowers; large shrub or small tree in South and West; ability to flower on new growth is an asset.

CULTIVARS:

'Cannabifolia'—Has marijuana-like foliage, the leaflets lightly incised/cut along their margins; produces lilac to lavender flowers.

'Heterophylla' (var. *heterophylla* (Franch.) Rehder)—The leaflets are gray-green and finely divided creating a graceful, airy texture especially when treated as an herbaceous perennial and grown primarily for its foliage; based on my evaluations at the Arnold, this form appears hardier than *V. agnus-castus* var. *latifolia*; GRIN lists var. *heterophylla* as a synonym of var. *incisa* (Lam.) C.B. Clarke.

'Incisa'—As I viewed it at the Arnold Arboretum, with more deeply cut leaflets than 'Heterophylla'; one could discourse that it is logical to aggregate all the cut-leaf types under one domain.

PROPAGATION: Softwood cuttings root like weeds but must not be left in the mist too long after rooting; this applies to *V. a.* var. *latifolia*; seeds can be directly sown; seedlings will flower in a single growing season.

ADDITIONAL NOTES: The *Vitex* species make attractive summer flowering garden plants but are not common. See Dirr, *American Nurseryman* 150(3):11, 75–78 (1979) for additional information. Good plant for hot climates and might even be grown as a small tree. Will flower recurrently during late summer as long as new growth develops. Not a bad idea to remove spent flowers since this may result in a late season flush of growth.

Vitex negundo has been shown to have repellent, insecticidal, and juvenile hormone activity against several insect pests, including stored product pests and larvae of Lepidoptera.

Some 250 species of trees and shrubs with opposite leaves, finger-like, 1 to 7 foliate leaflets, white, yellow to blue-violet flowers, found in tropics with a few temperate species. Occasionally see *Vitex trifolia* L. in Florida. It has 1 to 3 leaflets, to 10" long, panicles of fragrant to blue-purple flowers. 'Fascination' has purple-blushed leaves, 4" long, that are dark purple on lower surface; bluish purple flowers borne in airy panicles; dieback shrub in Zone 7 to 8. There is a purple-leaf type ('Purpurea'), green above, gray-purple below. 'Variegata' with cream-edged leaves is available. Trends toward an evergreen nature in central Florida where I observed it in March still holding the majority of its leaves. Asia to Australia. Zone 9 to 10. *Vitex rotundifolia* L.f. is a prostrate-sprawling shrub, growing 1 to 2' high and spreading indefinitely. Leaves a bluish green, about 2" long by 1 1/2" wide, broad-oblong to suborbicular. Flowers are blue-purple in short inflorescences out of the leaf axils. Good beach plant, excellent salt tolerance. Hybrids with *V. agnus-castus* exist and are intermediate in foliage, with small blue-flowered inflorescences on a more-refined, shrub habit. Actually quite handsome intermediate. Concern over *V. rotundifolia* and potential invasiveness in maritime environments. The literature devoted to invasiveness is frightening. For a healthy dose, visit the Global Invasive Species Database, www.issg.org. Had a plant in the Georgia trials and although the blue flowers were not potent, the blue-green foliage and aggressive growth rate made for a quick-fix, respectable ground cover. *Vitex rotundifolia* has colonized beaches on the North Carolina coast. At Wrightsville Beach, the species was out-maneuvering all other vegetation. Asia to Australia. Zone 7 to 10.

NATIVE HABITAT: Actually rather wide-ranging from southeast Africa, Madagascar, eastern and southeastern Asia, Philippines. Introduced 1697.

RELATED SPECIES:

***Vitex agnus-castus* L.** — Chastetree
(vī'teks ag'nus-kās'tus)

LEAVES: Opposite, compound palmate, digitate (finger-like) in appearance, 5 to 7(9) radiating leaflets, each narrow elliptic to lanceolate, 2 to 4"(5") long, 1/2 to 1" wide, tapering at the apex and base, entire or toothed toward apex, dark gray-green (almost blue-green) above, grayish beneath with a fine pubescence, leaves aromatic when bruised; petiolule—1/4" long or less.

Vitex agnus-castus, Chastetree, is not as hardy as the above species. The flowers are more prominent, lilac or pale violet, fragrant (although I can't detect much), and occur from June–July through September. Flowers occur in 3 to 6" long racemes from the ends and leaf axils of the current season's growth resulting in 12 to 18" long and slightly less in spread panicles. This species grows 8 to 10' high. In the South, it makes a fine small, 15 to 20' high and wide tree and is spectacular in flower. National champion is 26' by 37' in Johnson City, TX. The bark on old plants is grayish and develops a blocky characteristic. There are many fine specimens on the Georgia campus. Native to southern Europe and western Asia. Introduced 1570. Zone (6)7 to 8(9).

CULTIVARS:

'Abbeville Blue'—Produces deep blue flowers; selected in early 1990 by Louisiana Nursery.

'Alba' (f. *alba* (Weston) Rehder)—White flowers.

'Arnold's Cutleaf'—Dissected leaflets like a dissected Japanese maple, blue-purple-lavender flowers, grows 10' by 10'.

'Blushing Spires'—Soft pink flowers, growth more restrained; from Niche Gardens, North Carolina.

'Fletcher Pink'—A pale pink to lavender-pink flowered selection.

var. *latifolia* (f. *latifolia* (Mill.) Rehder)—Supposedly more vigorous and hardier than the species; I remember learning the variety in my plant material courses at Ohio State, for it was always necessary to hunt through the old Horticulture garden to see if there were a few live branches.

'Lilac Queen'—Lavender flowers, broad-spreading, multi-stemmed shrub, 20' by 18', introduced by Plantation Tree Co., Selma, AL.

'Mississippi Blues'—More compact selection yet still will grow to 12'; robust grower with deeper blue flowers similar to 'Abbeville Blue'; there are essentially no differences in flower color among 'Mississippi Blues', 'Abbeville Blue' and 'Shoal Creek' based on comparisons of the three cultivars in Georgia trials.

'Montrose Purple'—Produces rich violet flowers in large inflorescences; strong-growing form, 8 to 10' by 8 to 10'; rated just after 'Shoal Creek' in Longwood *Vitex* trials; an introduction by Nancy Goodwin, Hillsborough, NC.

'Rosea'—Pink flowers

'Salinas Pink'—Light pink flowers on smaller inflorescences than most blue-flowered forms; vigor is not as potent as 'Shoal Creek' and others; seedling populations at the University of Georgia and Plant Introductions, Inc. resulted in a few blues and no pinks better than maternal parent.

'Shoal Creek'—Large, blue-violet flowers in 12 to 18" long inflorescences and leaf spot resistance, although have observed leaf spots on plants under overhead water; rated highest in Longwood *Vitex* trials, see *American Nurseryman* 204(6)26–34, 2006.

'Silver Spire'—Cleaner white flowers than 'Alba' and good vigor.

'Snow Spire'—White flowers in panicles as large as the species.

'Woodlanders White'—Another white-flowered selection.

Vitex agnus-castus*Vitis* L. — Grape

FAMILY: Vitaceae

Vitis escaped earlier editions of the *Manual*, but now has been given a small presence. With some 65 species worldwide, anything I include is superficial. In European gardens several species and cultivars are used repeatedly. The species most common in the wild in the midwestern and eastern United States include: *V. aestivalis* Michx., Summer Grape; *V. cinerea* (Engelm.) Engelm. ex Millardet, Sweet Winter Grape; *V. labrusca* L., Fox Grape; *V. riparia* Michx., Frost Grape; and in the southeastern United States, *V. rotundifolia* Michx., Muscadine Grape, around which a small industry has evolved due to breeding efforts at the University of Georgia.

Childhood days were often spent with my buddies swinging from wild grapevines (identity not important). Our Tarzan impressions were feeble—the dreaming was important. I remember the rich brown, shreddy-barked stems and trunks that ascended the trees. If only I could climb those vines, then and now.

Suffice it to add that *Vitis* beyond the commercial production has not become an ornamental plant of significance in United States' gardens. Maintenance, primarily pruning, is necessary. I have grown *V. rotundifolia* and *V. coignetiae* in the Dirr garden. Both were removed. The former too vigorous; the latter did not live up to the fall color expectations.

Vitis coignetiae Poll. ex Planch. — Crimson Glory Vine
(vī'tis kog-net'ē-a)

LEAVES: Alternate, simple, rounded, to 10 or 12" long by 10" wide, 3- to 5-lobed, acute, cordate, dentate, dark green above, tomentose below; petiole—2 to 6" long.

Vitis coignetiae is a rampant climber that scrambles to the tops of tall trees in its native Korea and Japan. The dark green leaves turn rich crimson and scarlet in fall. In Athens, newly tested plants developed excellent red fall color under 50% shade. The 1/3 to 1/2" diameter, glaucous purple-black fruits are barely edible. Claret Cup™ ('Frovit')—young leaves are rich coppery-purple turning green as they mature, vivid scarlet-crimson in fall. Japan, Korea. Cultivated 1875. Zone 5, possibly into 7.

Vitis rotundifolia Michx. — Muscadine Grape
(vī'tis rō-tun-di-fō'li-a)

LEAVES: Alternate, simple, rounded to broad-ovate, 2 1/2 to 5" high and wide, acute, cordate, occasionally slightly lobed, coarsely serrate, glossy dark green above, glossy yellow green below, glabrous except hairs in axils of veins; petiole—usually shorter than blade.

Vitis rotundifolia is a phenomenally vigorous (over 100') and long-lived vine that permeates much of the Southeast. The leaves turn a pleasing yellow in fall. Fruits are rounded, greenish to purplish, 1/3 to 1" diameter, with a thicker skin. As I have eaten them: pop in mouth, extract skin, savor sweet juice on outside of interior, remove rest. Used for jellies, jam, wine and ammunition. Many cultivars of outstanding merit bred and introduced by Griffin, GA scientists. As I walk the woodlands of the Southeast this plant is everywhere. Also, common in older southern gardens and farmsteads. Delaware to northern Florida, west to Missouri, Kansas, Texas and Mexico. Introduced 1806. Zone 5 to 9.

Vitis vinifera L. — Common Grape
(vī'tis vī-nif'ēr-a)

LEAVES: Alternate, simple, 3- to 7-lobed, 2 to 6" high and wide, cordate, irregularly dentate, dark green above, variably pubescent, tomentose beneath.

Vitis vinifera is the grape of commerce with hundreds of selections over the centuries. Again, like the above it can reach tall trees and grow over 100' long. Several ornamental cultivars with deeply lobed leaves ('Apiifolia', 'Ciotat'), purple-leaf types ('Madame Mathias Muscat', 'Purpurea') and cream-variegated leaves ('Variegata') are known. The purple-leaf types are utilized in European gardens, less so in the United States. Southern and central Europe. Cultivated for centuries. Zone 6 to 9.

Weigela florida (Bunge.) A. DC. — Old Fashioned Weigela
(wī-gē'la flōr'i-da)

FAMILY: Caprifoliaceae, Diervillaceae by GRIN

LEAVES: Opposite, simple, elliptic to ovate-oblong, or obovate, 2 to 4 1/2" long, 3/4 to 1 1/2" wide, acuminate, rounded to cuneate at base, serrate, medium green and glabrous above except on mid-rib, pubescent or tomentose on veins beneath; petiole—short, about 1/8 to 1/4" long.

STEM: With 2 rows of hairs running from node to node, gray-brown, scurfy, with large circular lenticels; pith—moderate, pale brown, continuous.

SIZE: 6 to 9' high by 9 to 12' wide; smaller in exposed and harsh situations.

HARDINESS: Zone 5 to 8(9); most of the older cultivars are not cold hardy in Orono, ME but the Dance (Canadian) hybrids have performed extremely well.

HABIT: Spreading, dense, rounded shrub with coarse branches that eventually arch to the ground.

TEXTURE: Medium in summer, at times almost offensive in winter.

LEAF COLOR: Nondescript medium green, no fall color of consequence.

FLOWERS: Perfect, funnelform-campanulate, 1 to 2" long, abruptly narrowed below the middle, rosy pink outside, paler within, with rounded spreading lobes, May–June (mid to late April, Athens; early May, Chapel Hill, NC), singly or several in axillary cymes on short twigs from last year's branches, also flowering sporadically on current season's growth, have seen flowers as late as mid-October.

FRUIT: Two-valved, glabrous capsule of no ornamental value, to 1" long; seeds unwinged to slightly winged.

CULTURE: Transplant bare root or from a container; extremely adaptable but prefers a well-drained soil and full sun; shade is a killer; often considerable dieback occurs and pruning (after flowering) is necessary to keep it in shape; quite pollution tolerant; drought in Southeast 2005–2007 wrecked havoc.

DISEASES AND INSECTS: None serious, viruses have been reported, *Plant Disease* 77(3):318 (1993); Japanese beetle, four-lined plant bug, leaf spots & crown gall are listed.

LANDSCAPE VALUE: Best used in the shrub border, for grouping or massing; have seen it used frequently as a foundation planting in older sections of cities; really appears forlorn in the winter landscape; looks like it needs a place to hide; many new, relatively compact types with deep maroon-purple foliage and brighter flower (more red) colors; in spring, early summer, they are great; less so later in the heat and drought; are better suited to Zone 6 and colder; have observed many in Minnesota, especially the Canadian series which are the most hardy; certainly will grow in Zone 7(8), but later in season look tired.

CULTIVARS: One truly needs a score card to keep track of the many cultivars that have resulted from hybridization among the various species. A glance at the list is sufficient reason to throw the hands in the air and give up. Krüssmann mentions that there are 170 known hybrids that resulted from the work of van Houtte, Billard, Lemoine and Rathke. Svejda from Agriculture Canada introduced several cold hardy, compact, free-flowering forms since the 1983 edition of the *Manual*. Pellett and McNamara, *Landscape Plant News* presented acclimation data for 18 *Weigela* taxa; on December 2 'Centennial' was the hardiest (–40°F); followed by 'Java Red', 'Minuet', 'Polka', and 'Samba' at –36°F; 'Rumba' at –32°F; 'Pink Delight', 'Tango', and 'White Knight' at –29°F; 'Gustav Melquist', 'Pink Princess', 'Red Prince', 'Rosabella', and 'Vanicek' at –26°F. The cultivars listed here are not necessarily progeny of *W. florida*. More recent cultivars, Wine and Roses®, 'Dark Knight', Midnight Wine® and others are typically smaller in stature with dark burgundy to wine-purple foliage. Renewed enthusiasm for the genus resulted from these new cultivars. In early May, a large planting of 'Bristol Ruby' (red) was in flower on the UNC campus. I noticed because of the flowers. The other 50 weeks, there are no smoke signals. This edition includes 20 new selections.

'Abel Carriere'—Large, rose-carmine flowers flecked gold in the throat, free-flowering, buds carmine-purple; 1876, Lemoine.

'Avalanche'—Vigorous, free-flowering, white form, the flowers with pink tinge; 1909, Lemoine; a *W. praecox* selection.

'Boskoop Glory'—Large, trumpet-shaped, salmon-pink flowers; about 7 to 8' at maturity.

Briant Rubidor™ ('Rubidor', 'Olympiade', 'Rubridor', 'Rubigold')—Exact floral (red) and foliage (yellow) characteristics as 'Rubigold'; until somebody tells me something different, I will stay with the multiple name theory for one plant; 5 to 7' high. ('Rubigold'—Have seen this at Bressingham Gardens in England and find the yellow or yellow-green splashed foliage and red flowers a degree indigestible but

- for those who want bright foliage and flowers it might be worth a shot; might cook in heat of South or at least fade quickly; a branch sport of 'Bristol Ruby'; actually grew in Dirr garden, hired a hit gardener to eliminate it.)
- 'Bristol Ruby'—Ruby red flowers, erect growth habit, free-flowering; a hybrid between *W. florida* and 'Eva Rathke'; 7' high, 10' high at Hillier, 1999; good hardiness; 1954.
- 'Bristol Snowflake'—White, with some pink; more vigorous than 'Candida'; 1955.
- 'Buisson Fleuri'—Large shrub at Hillier, flowers deep rose-red, spotted yellow in the throat; flowering May 31, 2006.
- 'Canary'—Yellow-flowered form; selected by Dick Lighty, Mt. Cuba Center, Greenville, DE; listed as a *W. subsessilis* selection, could be related to *W. coraeensis* Thunb., nomenclature is somewhat unclear; plants I have seen at the Arnold Arboretum open yellow, fading to pink, or have pink and yellow flowers mixed; grown from seed obtained from Korea; grows 10' by 10'; flowers in mid-Atlantic region in mid to late April.
- 'Candida'—Pure white in bud stage and older flowers; foliage light green; 1879.
- Carnaval™ ('Courtalor')—More compact and restrained growth habit; red, white and pink, thickish, substantive flowers occur in great profusion; triploid hybrid, French origin; 4 to 5' high; not sure about nomenclature (i.e. two cultivar names but have seen it listed such in commerce).
- 'Centennial'—Robust shrub to 9' with erythrite red flowers to tips of branches; cold hardy form introduced in 1967, hybrid between 'Dropmore Pink' and 'Profusion'.
- 'Conquête' ('Conquerant')—Very large, deep pink flowers almost 2" long; spreading habit; 1904, Lemoine.
- 'Dame Blanche'—Almost pure white but with a pink tinge, large flowers; 1902, Lemoine.
- 'Dark Horse' (PP 14,381)—Compact mounded habit, 2' by 3'; deep purple-black leaves with lime-green venation hold during growing season (England); deep pink, trumpet flowers; bred by Peter Moore, Longstock, England.
- 'Dart's Colordream' ('Colourdream')—Cream and rose-red, while others are mixed; will be in the medium size category, probably 4 to 6' high.
- 'Dropmore Pink'—Hardy pink form developed by Dr. Skinner using a Manchurian strain for hardiness, 1951.
- 'Eva Rathke'—A slow-growing cultivar of compact habit with bright crimson-red flowers with yellow anthers, opening over a long period; 1892, Rathke.
- 'Eva Supreme'—Vigorous grower with bright red flowers; hybrid of 'Eva Rathke' and 'Newport Red'; supposedly only 5' high; limited repeat flower; quite cold hardy; 1958, Holland.
- 'Evita' (PP 5,555)—Resembles 'Eva Rathke' in flower color, crimson red with yellow anthers, but is dense and spreading in habit, 2 to 3' high, 4 to 5' wide; flowers profuse in May–June, with recurrent bloom later; good looking form; 1' high at Minnesota Landscape Arboretum, beat-up specimen, July 20, 2005.
- Eyecatcher™ (PPAF)—Yellow-margined, green-centered variegated foliage and dark red flowers; listed as 2' by 3', I have doubts about size; described as superior to French Lace™; from David Tristram, Walburton Nursery, England; plant at Hawksridge was vigorous.
- 'Fairy'—Large trusses of bright salmon-pink flowers; 4 to 5' high.
- Feline™ ('Courtamon')—Long trumpet-shaped white and pink flowers on a 6', erect, eventually arching shrub.
- Fine Wine™ ('Bramwell', PP 18,513)—Compact mounded, 2 to 2 1/2' by 3 to 3 1/2'; dark burgundy foliage; pink flowers.
- 'Floreal'—Clear rose-pink outside, deep carmine-pink throat, large-flowered, floriferous; 1901, Lemoine.
- 'Foliis Purpureis'—Pink flowers with purplish green foliage; dwarf, for a 20-year-old plant is purple-red, densely rounded and 4' tall; a *W. florida* form; buds carmine red, same as 'Java Red'.
- French Lace™ ('Brigela', PP 12,666)—Yellow leaf margins; red flowers; 4 to 6' high and wide; observed in England, I have doubts about performance in Zone 7 and South; flowered in Athens area with leaves becoming more green and losing strong variegation.
- Ghost™ ('Carlton', PPAF)—Foliage is cream-yellow-green; flowers dark reddish pink, shows reblooming tendency; 4 to 5' by 4 to 5'.
- 'Gold Rush'—Gold and green leaves; light pink flowers; 4 to 5' by 4 to 5'; from the Netherlands.
- 'Gracieux'—Erect, free-flowering, salmon-rose with sulfur yellow throat, large-flowered, floriferous; 1904, Lemoine; 8' high at Hillier, 1999.
- 'Java Red'—Somewhat confused in my mind, similar to 'Foliis Purpureis'?; carmine red buds open to deep pink (rose-pink) flowers; more compact-spreading, 3 to 4' by 4 to 5'; foliage deep green with a purplish red overcast.
- 'Jean's Gold'—A golden-foliaged branch sport of 'Bristol Ruby'; red flowers; more resistant to sun-scorch; first noticed by Staffordshire, England nurseryman Paul Zako in 1988.
- 'Jitsuko's Gold'—An all yellow leaf form with pink flowers named after the late wife of Ozzie Johnson; 6' by 6'; discovered by Dan Hinkley in the mountains of Japan.

- 'Joep'—Appears to be toned-down version of 'My Monet'; leaves variegated but less so and with more chlorophyll; did not notice burn/necrosis on plants in full sun at Bailey's; not sure of introduction status.
- 'Looymansii Aurea'—Is a form that jumps in my path in many European gardens; the leaves are bright golden yellow with a narrow, red, marginal rim, foliage will fade with heat and probably scorch in the heat of the United States summers; flowers are pink and habit is more restrained than *W. florida* but still 4 to 6' high at maturity.
- Lucifer™ ('Courtared')—A compact form, 3 to 5' high with dark green foliage and large, 1 3/4" long, deep red flowers.
- Magical® ('Kolsunn', PP 13,567)—Dark green leaves with broad cream-white margins; margins become greener with age; solid pink flowers; 3 to 4' by 3 to 4'; for all the world looks like 'Variegata', perhaps smaller; Zone 4 to 8; selected by Peter Kolster, Netherlands, introduced by Monrovia Growers.
- Midnight Wine® ('Elvera', PP 12,217)—Dwarf version of Wine & Roses®; dense metallic burgundy foliage; deep pink flowers; 18 to 24' high and wide; absolutely fried at Dearing, GA by early August; truly compact but fried.
- Minor Black™ ('Verweig3')—Deep maroon leaves; bright pink flowers; 3' by 3'.
- 'Minuet'—Very dwarf compact form with dark ruby red flowers profusely borne over the purple-tinged, dark green foliage, flowers slightly fragrant; 30" high; has shown excellent cold hardiness; flowers are ruby red on outside of corolla, lobes lilac-purple, throat yellow, 1 1/2" long, 1 1/4" wide; released by Agricultural Canada, parentage 'Foliis Purpureis' × 'Dropmore Pink'; see *Canadian J. Plant. Sci.* 62:249–250 (1982); grew in Dirr garden, pretty tatty by end of summer, eventually removed.
- 'Mont Blanc'—Vigorous form with large, white, fragrant flowers; often considered the best white; 1898, Lemoine.
- My Monet™ ('Verweig', PP 16,824)—Great name, so-so plant, especially under heat and drought conditions; first experienced in England and when well-watered, fertilized and climatized, looks great; leaves white-pink variegated; a sport of 'Tango', which has reddish flowers; 12 to 18" high, about the same width; in England, the plant was labeled Monet™ and the photo tag showed rich pink-white-green assemblage of foliage; the plant to which the tag was attached had relatively small, ovate-elliptical leaves with off-green centers and narrow pink margins on May 30, 2006 at Fairweather Garden Center, Beaulieu; widely promoted in U.S., reverts with fervor, cooks in heat; even a Minnesota grower provides shade.
- Nain Rouge™ ('Courtanin')—Bright orange-red flowers with creamy white stigma and style; rich green leaves turn red in fall; 2 to 3' high; French introduction.
- 'Newport Red' ('Vanicek')—Similar to 'Eva Rathke', flowers not as bright and more purple-red; vigorous grower; winter stems green, the same as 'Vanicek' and, in fact, introduced by V.A. Vanicek, Newport, RI; 5 to 6' high; good hardiness.
- 'Pink Delight'—Deep pink flowers that do not fade as blatantly as many forms, more compact habit, greater cold hardiness, 5 to 6' by 5 to 6'; from Mission Gardens, IL.
- Pink Poppet™ ('Plangen', PPAF)—Almost a low groundcover as I witnessed the plant; extremely shiny dark green foliage for a *Weigela*; 2' by 3 to 4'; light pink flowers, late April–early May, Zone 7, will repeat; from the Czech Republic at the Research Institute of Ornamental Gardening, Pruhonice.
- 'Pink Princess'—A pink-flowered (actually lavender-pink), hardy selection from Iowa State University; 5 to 6' high, spreading, loose, open; does not flower as heavily as 'Polka'.
- 'Polka'—Develops into a 3 to 4' high, 4 to 5' wide shrub; foliage is thick and dark green, leaves 2 1/2 to 3" long, 1 1/2 to 2" wide; flowers are pink on outside of the corolla with a yellow inner throat and average 1 3/4" long, 1 1/4 to 1 1/2" wide; suffered 7% winter injury in Ottawa and flowered for 10 to 11 weeks from June to September; counted 12 progenitor taxa in this clone's makeup, Wow!; see *HortScience* 23:787–788 (1988) for additional details; 5', loose habit, July 20, 2005, Minnesota Landscape Arboretum.
- 'Red Prince'—Good red flower that does not fade, full flower early April in Zone 7, recurrent flowering in late summer, 1 1/3" long, 1" wide; upright growing when young, 5 to 6', hardier than 'Newport Red' ('Vanicek'), listed as adaptable to Zone 4, introduced by Iowa State University, see *HortScience* 26(2):218–219 (1991); handsome planting in Spring Grove, Cincinnati; mid green leaves and stronger stems make for a better shrub than old reds like 'Bristol Ruby'.
- 'Red Trumpet'—Relatively compact, 4' high; abundant deep rose flowers face up and out; mid green leaves; bred by Peter Moore; quite showy as the flowers really jump out.
- 'Rubies N Gold'—Yellow-gold leaf selection that was starting to discolor (photo-bleach) on May 19, 2007 at the Center for Applied Nursery Research, Dearing, GA; have yet to see flowers.
- 'Ruby Queen' (PP 12,632)—Semi-dwarf, 2 to 3' by 2 to 3'; red-burgundy leaves, larger and more rounded than Midnight Wine®; smaller than Wine & Roses®.
- 'Rumba'—Vigorous, compact-spreading shrub, 3' by 3 1/2' wide; yellow-green leaves with purple edges, 3" long by 1 1/2" wide; flowers dark red with a yellow throat, 1 3/4" long and 1 to 1 1/4" wide; winter hardy and flowers for 8 weeks from June to September; see *HortScience* 20:149 (1985); result of cross between 'Foliis Purpureis' and 'Dropmore Scarlet'; 5' high, Minnesota Landscape Arboretum, July 20, 2005; leaves green at Bailey's, July 14, 2008.

'Samba'—Compact, vigorous, well-formed shrub that grows about 3' high and wide; leaves are dark green with purple tips and edges, 2 1/2 to 3" long, 1 to 1 1/2" wide; flowers are red with a yellow throat, 1 3/4" long, 1" wide; displays excellent winter hardiness; a hybrid between 'Rumba' and 'Eva Rathke', see *HortScience* 21:166 (1986) for details; 3' high, Minnesota Landscape Arboretum, July 20, 2005; small habit, green leaves, Bailey's, July 14, 2008.

'Seduction'—Magenta-rose, buds dark red, heavy-flowering.

Shining Sensation™ (PPAF)—Actually one of the best burgundy-purple leaf types I have observed; surface is shiny with good burgundy shade to overall leaf; habit appears compact; there are many purple-leaf types, and this appears to have commercial legs; 5 to 6' by 3 to 4'; pink flowers, May–June, and sporadically through summer; arching stems create graceful appearance; Novalis introduction in 2009.

'Silver Edge'—Thin white margin gives plant refined appearance; light pink flowers.

'Snowflake'—Profuse, white flowers; 3 to 4' high; good cold hardiness.

'Styriaca'—Small, carmine-rose flowers freely borne on arching branches; smaller shrub; foliage light green.

'Sunny Princess'—Golden bands along the leaf margin, otherwise like 'Pink Princess' from which it sported; not exciting.

'Suzanne'—White, pink flowers; narrow, white-margined leaf.

'Tango'—Compact shrub, 2' high by 2 1/2' wide; leaves 2 1/2 to 5" long, 3/4 to 2" wide, purple on the upper surface, dark green below, purple is predominant and maintained throughout the growing season; flowers are red on the outside, yellowish in the throat, 1 1/4 to 1 1/2" long, 3/4 to 1" wide; has shown a maximum of 4% winter injury in Ottawa, Canada, and flowered for 3 to 4 weeks in June (Canada); see *HortScience* 23:787–788 (1988) for more details; interestingly, this clone resulted from four progenitor taxa; 2 1/2' high, Minnesota Landscape Arboretum, July 20, 2005; leaves still purple July 14, 2008, Bailey Nurseries.

'Vanicek'—Same as 'Newport Red'.

'Variegata'—Flowers deep rose, leaves edged pale yellow to creamy white; compact grower, about 4 to 6' high although have seen 10' tall plants.

'Variegata Nana'—Most dwarf of the variegated weigelas, 3' tall, same foliage as above, again have seen larger specimens than the norm.

var. *venusta* (Rehd.) Nak.—Leaves smaller, flowers rosy pink, very hardy, free-flowering, listed as Zone (3)4.

'Versicolor'—Cream-colored flowers mixed with pink, rose, red flowers on the same plant; foliage green; 5 to 6' high and wide.

'Victoria'—May be the same as Wine and Roses® which is trademarked and if sold under that name a royalty fee is assessed; from my literature searches, it appears 'Victoria' was being sold by a number of United States nurserymen *before* the trademarked version appeared; was told that 'Victoria' is different, i.e., larger growing; RHS Plant Finder 2008–2009 lists it as a distinct cultivar.

'White Knight' (PP 8,348)—Smaller than species, 5 to 6' high and wide; medium green foliage; large pure white flowers in our Georgia trials, flowers are lovely; was a sprawly, erratic grower and soon became unwelcome; I assess many of the Georgia trial plants with the question . . . "Who would buy this?"; Iowa State University introduction.

Wine & Roses® ('Alexandra', PP 10,772)—Compact shrub, 4 to 5' high and wide with dark burgundy-purple leaves and hot rose-pink flowers; have seen small plants and they do have customer appeal in a container; again, foliage fades to green with purple hues in heat of Zone 7 and south; plant was widely promoted and has become mainstream, certainly better in cooler climates; larger and looser than originally described.

A final check of cultivar mayhem using RHS Plant Finder 2008–2009 as the arbiter showed 'Anne Marie', Cappuccino™ ('Verweig2'), 'Golden Candy', 'Gustave Malet', Moulin Rouge™ ('Brigela'), Naomi Campbell™ ('Bokrashine'), 'Stelzneri', and 'Wessex Gold' were missing from the *Manual* treatment.

PROPAGATION: Seeds can be directly sown; softwood cuttings in May, June, July, August root readily; one of the easiest plants to root; tissue culture has been successful, protoplasts have been regenerated into whole plants, see *Plant, Cell, Tissue and Organ Culture* 33(3):315–320 (1993).

ADDITIONAL NOTES: Cultivars, cultivars, and more cultivars. At Hillier Arboretum several years past I observed and photographed a number of *W. praecox* (Lemoine) L.H. Bailey French-named hybrids. Also, at Glasnevin, Ireland, an entire collection of cultivars confused me to the point where all looked the same. Without labels I am lost. Have also seen *W. japonica* Thunb. in flower without knowing it was different from *W. florida*. Considering that some 10 species are recognized it might be easier to lump them together. The numerous hybrids preclude any type of sanity at taxonomic order. All are found in Japan (greatest number), China, Korea, and Manchuria.

NATIVE HABITAT: Japan. Introduced 1860.

RELATED SPECIES:

Weigela coraeensis Thunb., (wī-gē'la kôr-ē-en'sis), produces 1 1/2" long, cream-yellow, pink, changing to carmine flowers in 2- to 8-flowered, axillary cymes. Quite handsome in flower, 5 to 6' high and wide. 'Alba' produces cream-white flowers maturing to pale pink-rose. Japan. Cultivated 1850. Zone 6 to 7. Also, ***W. praecox*** (Lemoine) L.H. Bailey, (wī-gē'la prē'koks), produces pale yellow flowers that fade to soft pink, finally deep pink. Early flowering, often mid to late March in Zone 7. Japan, Korea, Manchuria. Cultivated 1894. Zone 5 to 7.

Weigela decora (Nakai) Nakai, (wī-gē'la dē-kor'a), produces white to rose flowers in mid May on a medium-sized shrub. The leaves are slightly lustrous and darker green than the typical *Weigela*. Performed well at Raulston; the accession was listed as var. *amaglensis*. Japan. Cultivated 1933. Zone 6 to 7.

Weigela japonica Thunb., (wī-gē'la ja-pon'i-ka), is a 10' tall shrub with mid green, 2 to 4" long leaves; white, pale rose to carmine, 1 to 1 1/4" flowers in May. 'Sinica' (var *sinica* (Rehd.) Bailey) is similar but larger in habit. Described growing to 10', the lone plant at Hillier, 1999, was 6' high. Central China. Introduced 1908 by E.H. Wilson. The species is native to Japan, introduced 1892. Probably Zone 5 to 6 (7). Variety *sinica* is listed as *W. sinica* (Rehd.) H. Hara in GRIN.

Weigela middendorffiana (Carr.) K. Koch, (wī-gē'la mid-en-dôr-fi-ā'na), Middendorf Weigela, is a small (3 to 5' high) shrub of note for the 1 to 1 1/2" long, sulfur yellow flowers, dotted orange on the lower lobes. Flowers late April in Zone 7. I have seen it at the Arnold Arboretum and, although interesting, cannot compete with the better hybrids. Manchuria, northern China, Japan. Introduced 1850. Zone (4)5 to 7.

Another soft yellow-green flowered species is ***W. maximowiczii*** (S. Moore) Rehd., (wī-gē'la max-im-ō-wix'ē-ī), a smaller shrub to 4' that flowers early in spring. China. Introduced 1915. Zone 5.

*Weigela middendorffiana*

Weigela subsessilis (Nak.) L.H. Bailey, (wī-gē'la sub-ses'i-lis), is a 4 to 5' by 4 to 6', compact, twiggy shrub with yellowish green flowers changing to shades of pink and pale lavender. I first experienced this species in spring of 1991 at the Arnold Arboretum and indeed the flowers were spectacular. Looked a little tatty by the end of summer. See *Arnoldia* 53(4):331–333 (1993). China. Zone 6 to 7.

Wisteria floribunda (Willd.) DC. — Japanese Wisteria

(wis-tē'ri-a flôr-i-bun'da)

FAMILY: Fabaceae, also placed in Papilionaceae

LEAVES: Alternate, pinnately compound, 10 to 15" long, (11)13 to 19 leaflets, ovate-elliptic to ovate-oblong, 1 1/2 to 3" long, acuminate, rounded at base, rarely broad cuneate, entire, bright green above, appressed pubescent when young, soon nearly glabrous; petiole—flattened at base.

BUDS: Narrowly oblong and acute at the tip with 3 outer scales, one scale usually surrounding the entire bud, reddish brown, pubescent, appressed.

STEM: Twines clockwise, somewhat angled, light tan or brown changing to gray-brown, 2 spine-like projections at the top sides of the leaf scar.

SIZE: 30' or more, essentially limited by structure on which it is allowed to grow; have seen plants 40 to 50' (70 to 80') high in trees.

HARDINESS: Zone (4)5 to 9, Cappelletto reported kill in Orono, ME.

HABIT: Stout vine, climbing by twining stems which turn clockwise developing twisted woody trunks several inches in diameter and requiring considerable support.

RATE: Fast, as is true with most vines; will grow 10' or more in a single season once established, especially in the South.

TEXTURE: Medium in leaf, somewhat coarse in winter.

BARK: On old trunks a grayish color, smooth and sometimes irregularly fluted; almost reminiscent of the bark of *Carpinus caroliniana*.

LEAF COLOR: Bright green, usually late to leaf out, no fall color of any consequence, a tad of yellow, have on rare occasions savored reasonably good yellow fall color, new growth often bronze or purplish.

FLOWERS: Perfect, violet or violet-blue, on old wood on short leafy shoots, each flower 1/2 to 3/4" long, on a 1/2 to 1" long pedicel, slightly fragrant, April–May (early to mid-April, Athens), borne in slender, 8 to 20" (16 to 48") long racemes, the flowers opening from the base to the apex; very lovely as the flowers open before or just as leaves emerge; not too many vines rival it for flower effect; flowers occasionally on new growth of the season.

FRUIT: Pod, brown, 4 to 6", October, persisting into winter, velutinous.

CULTURE: Supposedly hard to transplant and slow to establish; however, I have grown many in containers and have had no difficulty establishing them; plant in deep, moist, well-drained loam; pH adaptable although supposedly does better at a higher pH; in order to insure successful culture it is wise to use nitrogen sparingly for this promotes excess vegetative growth, use superphosphate, root prune, cut back vigorous growth leaving only 3 to 4 buds, plant in full sun and use named cultivars rather than seedling grown material; if left to its own devices, the plant can consume fences, trellises, arbors and people; indeed it is one of the most beautiful of all flowering vines and deserves first consideration where it can be maintained; although all types of horticultural voodoo and folk art are recommended to keep it flowering, in the South it is unstoppable; for two or more weeks in April in Athens the plant appears as common as Japanese Honeysuckle.

DISEASES AND INSECTS: Crown gall, leaf spots, stem canker, powdery mildew, root rot, tobacco mosaic virus, sweet potato leaf beetle, Japanese mealybug, citrus flata planthopper, fall webworm, black vine weevil and scale.

LANDSCAPE VALUE: Excellent flowering vine, nice over patios, on large structures, or trained into a tree form; needs ample support and metal pipe is recommended for it will actually crush wood supports with time; not the easiest plant to keep flowering and cultural practices must be fairly precise; certainly escaped and has strangled trees and shrubs in the South; difficult to eradicate as it suckers prolifically from root pieces; in 2007 an April freeze over Easter (about 26°F) eliminated the flowers from the Georgia trial plants; the American species, *W. frutescens*, which flowers later, was not injured.

CULTIVARS: Many and for the most part not too different from a 20' distance; Peter Varder's, *Wisterias*, Timber Press, 1995, is an excellent reference for those who want to delve deeper. Noted 37 cultivars listed as commercially available in RHS Plant Finder 2007–2008.

'Alba'—Racemes 11" long, moderate fragrance, dense, white; 13 leaflets.

'Beni Fuji'—Slightly fragrant, light pink flowers; 19 leaflets.

'Geisha'—White flowers.

'Honko Fuji'—Pink flowers similar to 'Rosea'.

'Issai' ('Domino')—Racemes 12" long, moderate fragrance, violet to bluish violet; 17 leaflets; have seen 'Issai' described as having 24 to 30" long racemes.

'Ivory Tower'—White flowers, abundantly produced, heady fragrance.

'Kuchi-beni' ('Lipstick', 'Peaches and Cream')—Pale mauve-pink, wings and keel purple at tips, in racemes to 8"; soft green new growth, yellow in fall; Hillier 1999 listed 'Lipstick' and 'Peaches and Cream' as synonyms.

'Kyushaku'—Racemes 26" long, fragrance fair, reddish violet to violet.

Lavender Falls™ ('Betty Tam', PP 19,655)—Large lavender flower racemes before foliage, then reblooms during the growing season; 20' to 30'; seedling discovered by Pat and Betty Tam, Tulsa, OK; introduced by Greenleaf Nursery Co.

'Lavender Lace'—Fragrant, lavender-mauve flowers, inflorescence 2 to 3' long.

'Lawrence'—Flowers pale blue with white keels, original plant 20' by 10', discovered in Brantford, Ontario, 1970; selected because of exceptional hardiness and floriferousness.

'Longissima Alba' ('Shiro Noda')—Racemes 15" long, good fragrance, white; 13 leaflets; plants I have observed had 24 to 36" long racemes.

'Macrobotrys' ('Multijuga')—Racemes 18 to 36" (48") long, fragrance excellent, lilac tinged blue-purple.

'Murasaki Naga Fuji'—Produces purple and white flowers in up to 3' long racemes.

'Murasaki Noda'—Racemes 10" long, fragrance fair, 15 leaflets, reddish violet to violet.

'Naga Noda'—Pale violet, very fragrant.

'Pink Ice'—Soft pink flowers.

'Rosea' ('Honbeni', 'Honey Bee Pink')—Pale rose, tipped purple, excellent fragrance, in long racemes to about 18".

'Royal Purple' ('Black Dragon')—Violet-purple, 12 to 14" long, slightly fragrant; 15 leaflets, bronze new growth.

'Sekine's Blue'—Flowers blue-violet, 6 to 7" long racemes.

'Shiro Naga Fuji'—Produces long, narrow, white racemes.

'Snow Showers'—Offers fragrant, white flowers to 2' long; RHS Award of Merit in 1931, Award of Garden Merit 1969.

'Texas Purple'—Violet-purple, precocious, a Monrovia offering.

'Variegata' ('Mon Nishiki')—Cream-flecked variegated foliage and pale blue-lavender racemes; in Zone 7 fades to green in the heat of the summer.

'Violacea'—Violet-blue flowers.

'Violacea Plena'—Double flowers, violet-blue, flowers rosetted, slightly fragrant; 13 leaflets; racemes 10 to 12" long.

'White Blue Eye'—Has a blue-purple spot on each flower, pretty on close inspection, am not sure about the validity of this name.

PROPAGATION: Seeds germinate readily without treatment; I have collected seed in fall and direct sowed them with good results; if seed is quite dry and hard, a 24 hour soak in warm water is recommended; May, June, July cuttings rooted without treatment; hardwood cuttings taken in late January rooted 43%, 2,000 ppm IBA produced greatest number of roots per cutting; cultivars are also grafted.

ADDITIONAL NOTES: No matter how many times I am asked to identify this and *W. sinensis*, the process is never easy. *Wisteria floribunda* leafs out perhaps two weeks earlier than *W. sinensis* and may be injured by late spring frosts. Also, there is a hybrid, *Wisteria ×formosa* Rehd., between the above species that was raised on Professor C.S. Sargent's estate, Holm Lea, Brookline, MA in 1905. Flowers open, or almost so, simultaneously along the length of the inflorescence. Other possible hybrids like 'Burford', 'Caroline' (see under *W. sinensis*) and 'Lavender Lace' are described.

The wisterias are lovely vines but do require considerable care. In the South (Zone 7 and higher) they are pernicious pests and *W. floribunda* can be found strangling everything in its grasp. Admittedly, it is quite pretty draped over and around trees especially during April. Must be used with a certain amount of discretion and a commitment to proper culture and pruning. Good articles on *Wisteria* selection and culture appeared in *Horticulture* 63(4):38–40 (1985), *The Plantsman* 6(2):109–122 (1984), *The Garden* 120(2):92–97(1995), and *Brooklyn Botanic Garden Plants and Garden News* 12(1):8–10 (1997).

NATIVE HABITAT: Japan. Introduced 1830.

RELATED SPECIES:

Wisteria brachybotrys Siebold & Zucc. (*W. venusta* Rehd. & Wils.) — Silky Wisteria
(wis-tē'ri-a bra-ki'bō-trēs)

LEAVES: Alternate, compound pinnate, 8 to 14" long, 9 to 13 leaflets, usually 11, elliptic to ovate, 1 1/2 to 3 1/2" long, 1/2 to 1 1/2" wide, short acuminate, rounded, pubescent on both surfaces, bright green above.

Wisteria brachybotrys, Silky Wisteria, offers 1" long, white, fragrant flowers that are borne in 4 to 6" long, 3 to 4" wide racemes; all flowers opening about the same time. The 6 to 8" long pod is compressed and densely velutinous. Turns counter-clockwise akin to *W. sinensis* but shoots pubescent when young. Variety *violacea* Rehd. is the wild form with violet flowers. Listed by Hillier, 2002 as 'Murasaki-kapitan'. The typical white form is now 'Shiro-kapitan.' 'Shiro-beni' has mauve pink flowers with a small yellow blotch. Japan, where it (white) was only known in cultivation; before 1900. Zone 5 to 8. At the Raulston, this is about the latest of the Asiatic species to flower, April 6, 2005, the stems, peduncles and pedicels covered with silky, silver-white pubescence. Listed to 30' and is quite vigorous based on observations at the Raulston and in England. Certainly not common in gardens.

***Wisteria frutescens* (L.) Poir. — American Wisteria**
(wis-tě'ri-a frū-tes'enz)

LEAVES: Alternate, compound pinnate, 7 to 12" long, 9 to 15 leaflets of uniform size, elliptic-ovate to oblong or oblong-lanceolate, 1 1/2 to 2 1/2" long, to 1 1/4" wide, glabrous and bright green above, slightly pubescent below.

Wisteria frutescens, American Wisteria, is a vigorous, climbing vine that grows 20 to 30' or more. The fragrant (not as potent as *W. floribunda*), 3/4" long, pale lilac-purple flowers have a yellow spot and are compressed into 4 to 6" long, dense villous racemes in June–August on the current season's growth. Early to mid May at Coker Arboretum, Chapel Hill, NC. Degree of fragrance is variable. I was unable to detect any fragrance in species (UNC, Coker Arboretum) and 'Longwood Purple' (Raulston). Flowers are much later than those of *W. floribunda* and *W. sinensis* and, in Athens, open from late April into May with recurrent flowering during summer on new growth of the season. Flowers appear after the foliage has developed. Handsome plant in leaf and flower; much more restrained than the Asiatic bullies. The pods are compressed, 2 to 4" long, and glabrous with the seeds more rounded than those of *W. floribunda* and *W. sinensis*. 'Amethyst Falls' produces beautiful, fragrant, lavender-blue flowers, introduced by Head-Lee Nursery, Seneca, SC. Received the 2006 Georgia Gold Medal designation for its garden merit. 'Aunt Maude' has blue-violet flowers, lightly scented, 12 to 18', Pine Ridge Gardens, Fall 2006. 'Kate's Dwarf' has finer foliage, 6" purple flower clusters are more compact; flowers at a younger age; not as invasive as species. 'Longwood Purple' produces light violet (lavender), 4 to 6" long, non-fragrant flowers typically 10 to 14 days ahead of species; full flower April 24, 2005, species May 13, 2005. 'Lynn Lowrey' produces lavender-lilac, minimally fragrant, 6 to 8" long racemes in mid May, Zone 7. 'Magnifica' has lilac flowers with a large yellowish blotch on the standard. 'Nivea' is a white-flowered form. Occurs naturally along moist shores of streams, ponds, lakes, borders of wet woodlands and swamps, moist to wet thickets. Virginia to Florida and Texas. Introduced 1724. Zone 5 to 9.

***Wisteria frutescens* var. *macrostachya* Torr. & A. Gray (formerly *Wisteria macrostachya* (Torr. & A. Gray) Nutt. ex B.L. Rob. & Fernald) — Kentucky Wisteria**
(wis-tě'ri-a mak-rō-sta'kēs)

LEAVES: Alternate, compound pinnate, about 9 leaflets, 1 to 3" long, ovate-elliptic to lanceolate, acuminate, bright green, pubescent above initially, finally glabrous, pubescent beneath.

Wisteria frutescens var. *macrostachya*, Kentucky Wisteria, is restrained, much like *W. frutescens*, and grows 15 to 25' long. The lilac purple flowers are packed 70 to 90 to the 8 to 12" long raceme and open in May–June and later. Flowers in June in Morton Arboretum. The 3 to 5" long, glabrous pod is often twisted. Probably the hardiest wisteria. Also, more moist to wet soil tolerant. 'Abbeville Blue' is blue-flowered; 'Aunt Dee' produces light purple, slightly fragrant flowers in 7 to 12" long racemes, succeeded in protected areas of Zone 4, performed well with longer, more cylindrical racemes at the Raulston, Zone 7; 'Bayou Two O'Clock' has lavender-lilac flowers in long-pointed, 8 to 12" long racemes, flowers early to mid April, Zone 7; 'Clara Mack' has white, lightly fragrant flowers in longer racemes, late flowering (May 12, 2005, Raulston), introduced by Woodlanders, selected by Columbia, SC gardener Clara Mack; 'Pondside Blue' has light blue flowers in full racemes. Kentucky and Tennessee, southern Illinois, Missouri and Texas. Survived –22 to –26°F at Madison, WI. Cultivated 1855. Zone (4)5 to 8(9).

***Wisteria sinensis* (Sims) DC. — Chinese Wisteria**
(wis-tě'ri-a sī-nen'sis)

LEAVES: Alternate, pinnately compound, 10 to 12" long, 7 to 13 leaflets, usually 11, ovate-oblong to ovate-lanceolate, 2 to 4" long, 1/2 to 1 1/2" wide, abruptly acuminate, usually broad-cuneate at base, ciliate, densely appressed-pubescent at first, deep green and glabrous above, somewhat hairy beneath, especially on the midrib.

Wisteria sinensis, Chinese Wisteria, is similar to *W. floribunda* except the flower is blue-violet, about 1" long, not as fragrant, May, borne in dense, 6 to 12" long racemes, all flowers of one raceme opening at about the same time. Fruit is a pod, 4 to 6" long, densely velutinous with 1 to 3 seeds. Twines counter-clockwise. The exact identity of this species has brought much hand wringing to the author especially when confronted with a shoot and no flower. It would seem that leaflet numbers should be a good criterion for separation from *W. floribunda*. I have seen true *W. sinensis* in the Netherlands and England and, indeed, the flowers open more or less at the same time along the axis of the raceme compared to the differential opening of *W. floribunda* from base to apex. The clockwise (*W. floribunda*) and counter-clockwise (*W. sinensis*) turnings also leave room for interpretations. Most plants I see in cultivation and escaped into the wild are *W. floribunda*, not *W. sinensis*. *Wisteria sinensis*, according to Bean, is more vigorous than *W. floribunda*. Perhaps this is true in England but is not the case in this country. Variety *alba* Lindl. ('Alba') has white flowers; 'Amethyst' has 12" racemes of light rose-purple flowers; 'Anwen' produces sweet fragrant, light

purple flowers, from Bloom River Gardens, Waltherville, OR, fax 541-726-4056; 'Augusta's Pride' is an early flowering, light lavender-lilac selection from the Augusta National Golf Course in Augusta, GA, the old vine still resides outside the clubhouse, no doubt planted by P.J. Berckmann in the 1950's; 'Black Dragon' has double, dark purple flowers; 'Blue Moon' is a bi-colored, blue-flowered form; 'Blue Sapphire' is an early-flowering form with fragrant, lilac to mauve flowers; 'Caroline' has very fragrant, deep blue-purple flowers; 'Cooke's Purple' offers large, fragrant, dark lavender-blue flowers; 'Fuji White' offers fragrant, white flowers; 'Jako' is a selected form of *alba* with extremely fragrant flowers in up to 12" long racemes; 'Larry's White' is a fragrant white-flowered form, precocious, see *The Garden*, 126(3):163 (2001); 'Plena' has double, rosette-shaped, lilac flowers; 'Prolifica' ('Oosthoeks Variety') is a vigorous Dutch clone with blue-violet flowers of the species, flowers before the leaves; 'Rosea' bears pink flowers in 12" long racemes; 'Shiro Captain Fuji' produces abundant, broad racemes of fragrant, white flowers; 'Showa Beni Fuji' has broad dark pink inflorescences; 'Sierra Madre' with white standard and lavender-violet wing and keel, very fragrant; and, 'Texas White' has larger inflorescences of white flowers than typical for the species, may be a *W. floribunda* type. Bacterial stem gall was caused by *Pantoea dispersa*, see *Plant Disease* 78(12):1217 (1994). Also, *Phyllosticta wistariae* causes leaf spots. China. 1816. Zone 5 to 8.

Wollemia nobilis W.G. Jones et al. — Wollemi Pine

(wol-lē'mē-a nō-bil'lis)

FAMILY: Araucariaceae

LEAVES: Opposite or sub-opposite, 4-ranked, long-persistent, narrow-oblong, 1 1/4 to 1 3/4" long, dark olive-green, leathery-pliable, needle base ensheaths the stem.

Wollemia nobilis, Wollemi Pine, has piqued curiosity since its discovery in 1994 by David Noble, growing in sandstone formations of the Wollemi National Forest, a rain-forest setting about 90 miles northwest of Sydney, Australia. About 40 trees exist in two areas in a narrow canyon. Trees in photos are pyramidal-conical, central-leadered, with spongy-bumpy bark. Described as bubbling-chocolate textured and colored bark. A monoecious species and cones may reach 5" in length, the scales shattering at maturity. Initially, there was great mystery and secrecy surrounding the species but it is now appearing more frequently in commerce, and is a poster species for conservation. At Wakehurst Place, England, a small plant was actually protected by a cage so visitors could not touch. I have only seen the plant three times, the latest on March 24, 2009 at the Raulston Arboretum and all the needles were killed at circa 15°F. Whether regeneration from the trunk will occur in 2009 is unknown. Tony Avent noted the species surviving 15°F and 106°F in the ground at his Plant Delights Nursery south of Raleigh. Suspect it is better suited to Zones 7 to 9 on the West Coast. Fossil records show it has been extant for 90 million years but has obviously lost ground. The discovery and subsequent distribution are positives in preserving the species. Described as reaching 100' and greater at maturity. The largest seen by the author was about 4'. Literature noted relatively moderate growth, 12" or more per year. Might prove a better conservatory plant than hardy landscape evergreen. Douglas Justice, University of British Columbia Botanical Garden, reported cold susceptibility with top half of plant killed in winter of 2008–2009 with a low of 7°F, snow cover accounting for the surviving lower one half. He mentioned that propagation is easy from cuttings. Introduced in 1994. New South Wales.

Xanthoceras sorbifolium Bunge — Yellowhorn

(zan-thōs'ēr-as sōr-bi-fō'li-um)

FAMILY: Sapindaceae

LEAVES: Alternate, compound pinnate, 5 to 9" long, 9 to 17 sessile leaflets, narrow elliptic to lanceolate, 1 1/2 to 2 1/2" long, deeply and sharply serrate, lustrous dark green above, lighter beneath, persisting late in the fall.

Xanthoceras sorbifolium is a striking tree or more often large shrub, but virtually unknown in commerce and gardens. It tends to be upright in habit and the branching pattern is rather stiff and coarse. Size ranges from 18 to 24'. The beautiful, slender-stalked, 3/4 to 1" diameter flowers occur in 6 to 10" long racemes in May. Each fragrant flower is composed of 5, rather thin, white petals with a blotch at the base that changes from yellow to red. It is a striking tree in flower and one which any gardener would be proud to display. Adaptable to any good loamy soil even those of calcareous origin (high pH). Supposedly has the reputation for being difficult to transplant. Should be sited in full sun. The fruit is a 3-valved, thick-walled, 2 to 3"(4") diameter, rounded capsule; each cell contains several globose, dark brown, large pea-sized seeds. The seeds, when roasted, supposedly taste a little like macadamia nuts. At a conference in Nebraska, I talked with a gentleman who said the tree was growing well in Blair, NE where winter lows reach -25 to -30°F. Does not prosper in the heat of the South. Seed requires no pretreatment although 2 to 3 months at 40°F may unify and hasten germination. Root cuttings offer a feasible means of vegetative propagation. The lustrous green leaves remain late in fall. Have seen the tree in flower around mid-May at the Wister Garden, Swarthmore, PA and Winterthur Gardens, DE. At the Arnold Arboretum, flowers peaked during late April-early May, 1991. It is striking and certainly the rival of any flowering tree. Northern China. Introduced 1866. Zone (3)4 to 6(7). Never thought I would experience a cultivar because of propagation difficulties . . . but Clear Creek™ ('Psgan'), 22' by 15', fragrant, white, yellow to red flowers, April-May, Zone 5 to 8, was introduced via the Plant Select® program at Colorado State University, Fort Collins.

Xanthorhiza simplicissima Marsh. — Yellowroot

(zan-thō-rī'za sim-pli-cis'i-ma)

FAMILY: Ranunculaceae

LEAVES: Alternate, compound pinnate, or appearing bipinnate, clustered at stem ends, leaflets usually 3 to 5, 1 1/2 to 2 3/4" long, the basal pair 2- to 3-lobed, ovate to ovate-oblong, incisely toothed, sometimes serrate, lustrous bright green.

BUDS: Lateral buds solitary, sessile, ovoid-oblong, compressed and flattened against stem, with about 3 scales; terminal buds (flower) much larger, fusiform, terete, with about 5 scales, red-brown.

STEM: Outer bark yellowish brown, inner bark yellow, branchlets pale greenish gray; pith large, round, continuous; leaf scars low, slightly curved, more than half encircling twig; about 11 bundle traces.

ROOT: Long, slender, deep yellow; hence, the name Yellowroot.

SIZE: 2 to 3' in height and spreading freely as it suckers from the roots, observed 5' high plants in Savill Gardens, England.

HARDINESS: Zone 3 to 9, in laboratory tests survived -55°F .

HABIT: A flat-topped ground cover with erect stems and celery-like leaves, filling the ground as a thicket; magnificent plant for difficult as well as normal sites especially where shade is a problem.

RATE: Medium.

TEXTURE: Medium in all seasons.

STEM AND ROOT COLOR: The inner bark and roots are yellow.

LEAF COLOR: Lustrous bright green in summer; very handsome foliage; fall color may develop golden yellow and orange, sometimes a slight purple fall color; holds late, have seen foliage in early December in Boston.

FLOWERS: Brownish purple, 1/6 to 1/4" across, star-shaped, usually occurring before the leaves in March–April, borne in 2 to 4" long racemes, forming a racemose panicle, not showy but interesting.

FRUIT: Follicle, single-seeded, pale brown.

CULTURE: Transplant in spring or fall; utilize container-grown plants or divide old plants and space these 18 to 24" apart; prefers moist, well-drained soils and here makes its best growth; will do well in heavy soils; does well under average conditions but is less invasive in dry soils; full sun or partial shade; thrives along streams and moist banks; avoid high pH soils for it will develop chlorosis.

DISEASES AND INSECTS: None serious.

LANDSCAPE VALUE: A very desirable ground cover for moist areas; little known and grown; makes a very solid mass; the more I see it the more I believe it has been slighted by American gardeners; had several clumps in my Illinois garden where it did quite well; did notice chlorosis in a high pH pocket of soil; have seen tremendous plantings at Arnold Arboretum, Smith College and Heritage Plantation that would be sufficient to entice anyone to find a place for it in their landscape; abundant in Southeast along water courses in the dense shade of large trees; appears to savor a cool, moist root run.

PROPAGATION: Most effective method is by division of the parent plant; root cuttings will also work and June shoot cuttings treated with 8,000 ppm IBA rooted in high percentages.

ADDITIONAL NOTES: From the juice (sap) the Indians extracted a yellow dye. Just a beautiful native that is extremely common along water courses in the southern Appalachians. Obviously is able to withstand flooding for certain periods. Lancaster, *The Garden* 120(12):742–743 (1995), offers a worthy treatise on the species. Also discussed in *Arnoldia* 54(2):31–35 (1994).

NATIVE HABITAT: New York to Kentucky and Florida. Introduced 1776.

Yucca L.

FAMILY: Agavaceae

There is a certain reluctance on my part to include these sword-like members of the Agavaceae but their use in landscaping, especially in the Midwest, Southeast, Southwest and West, is an undeniable and often horrible fact. When I see them in a landscape a feeling of Mexico or the desert Southwest arises. Several are native to the Southeast and they are treated here. Some 40 species of evergreen perennial herbs or trees, acaulescent or branched. Too many *Yuccas* are sufficient reason to cause one to YUK!

Yucca filamentosa L. — Adam's-needle Yucca

(yuk'a fil-a-men-tō'sa)

LEAVES: Sword-like and ready for battle, 1 to 2 1/2' long, 1 1/2 to 4" wide, abruptly narrowed at the apex where the margins are usually infolded (cusped); from the margins curly thread-like filaments, 2 to 3" long break away and are especially numerous toward the base.

Yucca filamentosa is a low evergreen shrub with stiffly erect and spreading leaves, the stem of which does not rise above ground level. The real attraction occurs during May–June (Athens), July–August (Urbana) when the 3 to 6' high, erect, conical panicles are covered with 2 to 3" diameter, yellowish white, pendulous

flowers. It is best used in mass and is not particular as to soil as long as it is not excessively wet. This is a very hardy species and can be grown as far north as Minnesota with some protection. It has long been confused with *Yucca smalliana* Fern. but that species has thinner, flatter, narrower leaves, 7/8 to 1 3/4" wide, long-tapered at apex. The central axis of the panicle is pubescent and the flowers are smaller (2" long). Listed by Monrovia is *Y. f.* 'Starburst' with narrow, long, green leaves striped with creamy yellow, tinged with pink in cooler weather; flowers like the species.

Another closely related species is *Yucca flaccida* Haw., Weakleaf Yucca, but the leaves of this species are 1 to 1 3/4' long and 1 to 1 1/2" wide and bent downwards, above the middle, long-pointed, with straight marginal thread-like fibers. The flowers are similar to *Y. filamentosa* but occur in a downy, shorter panicle. 'Golden Sword' has a green margin and yellow center while in 'Bright Edge' the color patterns are reversed. As near as I can determine they are *Y. flaccida* selections, although plants I have grown appear more like *Y. filamentosa* in habit. 'Ivory Tower' ('Ivory') forms a mounded rosette of sword-like leaves 3 to 4' high, tall panicles of ivory-white flowers occur in summer, from Monrovia. There are many variegated forms and unfortunately their taxonomic affinities elude this author. Banana Split™ ('Monril') has a bright yellow center, gray-green margin, a Monrovia introduction. 'Bright Edge' was included in the Dirr garden near a rock wall with lavender, rosemary, and thyme. A handsome combination and Bonnie was the orchestrator. 'Color Guard' ('Colour Guard') has luminous cream-yellow central striped variegation against green, turns rose in cold weather. 'Garland Gold' has rich broad golden interior bands on the green leaves, grows about 2' high, more intense than 'Golden Sword'. 'Hofer's Blue' is rich blue-green foliage as is 'Blue Sword'.

Yucca filamentosa occurs from South Carolina to Mississippi and Florida. Cultivated 1675. Zone 4 to 9. *Yucca flaccida* tends to be more inland from North Carolina to Alabama. Introduced 1816. Zone 4 to 9. *Yucca smalliana* occurs from North Carolina, west to Louisiana and Tennessee. Zone 5 to 9.

Yucca glauca Nutt. — Small Soapweed

(yuk'a glâ'ka)

Yucca glauca is an evergreen shrub with a low, often prostrate stem that carries a hemispherical head of leaves 3 to 4' in diameter. The glaucous green leaves are narrow linear, 1 to 2 1/2' long and 1/2 to 3/4" wide. They taper to a fine point with whitish margins beset with a few threads, the dull greenish white, 2 1/2 to 3" long, pendulous flowers occur on an erect, 3 to 4 1/2' high, rarely branched raceme. Flowers occur in July–August. Variety *stricta* (Sims) Trel. is a vigorous form with a more branched inflorescence; in 'Rosea' the flowers are tinted pink on the outside. South Dakota to New Mexico. Introduced about 1656. Zone 4 to 8. This is a rather attractive species especially for its foliage.

Yucca gloriosa L. — Spanish-dagger

(yuk'a glō-ri-ō'sa)

Yucca gloriosa is often encountered in the Southeast where it forms an evergreen shrub 6 to 8' high or more. National champion is 32' by 38' in Huntington Beach, CA. I have seen it branched but it often produces a single, thick, fleshy stem that is crowned with stiff, straight, 1 1/2 to 2' long, 2 to 3" wide, glaucous green, spine-tipped leaves. The leaves are usually entire. The pendulous, creamy white, often tinged red or purple, 4" diameter flowers occur on an erect, narrowly conical, 3 to 8' high, 1' wide panicle from July to September. *Yucca recurvifolia* Salisb., Curveleaf Yucca, is similar (to 6') except the upper leaves, 1 1/2 to 3' long, 1 1/3 to 2 1/4" broad, are recurved rather than straight as in *Y. gloriosa* and the inflorescence is more loosely branched. It is found along the coast of Georgia and Mississippi. 'Hin Vargas' (PP 12,192) has 1/25 to 1/8" diameter, yellow to yellow-green bands running the length of the leaves. 'Monca' (PP 14,616) is a compact grower with narrow, sword-like, dark and light green variegated leaves. 'Walbristar' (PP 17,653) has a broad, deep yellow margin. Introduced 1794. Zone 6 to 9. Listed as *Yucca gloriosa* var. *recurvifolia* (Salisb.) Engelm. by GRIN. *Yucca gloriosa* occurs from South Carolina to northeast Florida often on sand-dunes. Introduced 1550. Zone 6 to 9.

Propagation of the various species and cultivars is best achieved by dividing the fleshy roots (stems) and placing them horizontally in a suitable medium; shoots and roots regenerate from these pieces. Pollination of most species is effected by the pronuba moth. The moths emerge from the pupae before the flowering of the species with which they are associated. The female gathers pollen and rolls it into a ball; she then lays her eggs in the ovary of another flower and places the pollen-ball in the stigmatic chamber of the ovary. The grubs feed on the ovules but leave enough to supply adequate seeds. The yucca is entirely dependent on the moth and vice-versa. The seeds are black, compressed and remind of little wafers. They usually occur in great numbers. Seeds germinate without pretreatment but may take several months.

Zanthoxylum americanum Mill. — Prickly-ash, Toothache Tree

(zan-thō-zī'lum a-mēr-i-kā'num)

FAMILY: Rutaceae

LEAVES: Alternate, compound pinnate, 6 to 8"(12") long, 5 to 11, sometimes 13 leaflets, often with 1 or 2 spines on the main stalk where the leaflets are attached, leaflets 1 1/2 to 2 1/2" long, ovate to oval, lustrous dark green above, pubescent below, minutely or not serrated.

Zanthoxylum americanum is a seldom cultivated shrub or small tree (15 to 25') that is prominently armed with 1/3 to 1/2" long prickles. The dark green foliage is handsome and not susceptible to insect or disease problems. The yellowish green flowers occur in axillary clusters before the leaves on the previous season's wood. This is a dioecious species. The 2-valved, 1/5" long, red to black capsule matures in July–August and contains small, lustrous black seeds. This species might be used in poor soil areas or where a barrier plant is needed. Supposedly the stems and fruits were chewed by the Indians to alleviate toothache for the acrid juice has a numbing effect. From a landscape standpoint this is possibly the least desirable of the species treated here. Quebec to Nebraska and Virginia. Introduced about 1740. Zone 3 to 7.

RELATED SPECIES:

Zanthoxylum clava-herculis L., (zan-thō-zī'lum clā'va-hēr-kū'lis), Hercules-club, is a shrub or small tree, 25 to 30' high, usually smaller, with glabrous leathery dark green, compound pinnate leaves with 7 to 9(19) leaflets. National champion is 36' by 48' in Beaufort, SC. The leaves and stems are aromatic when bruised and an oil from the bark has medicinal qualities. Flowers are borne terminally. Virtually all parts of plant, including rachises, are covered with prickles/spines. The spines continue to enlarge and older branches/trunks are dotted with the protuberances. Important source of butterfly caterpillar food. Virginia along the coast to Texas and Oklahoma. Zone 7 to 9 (10).

Zanthoxylum piperitum (L.) DC., (zan-thō-zī'lum pī-pēr'i-tum), Japanese Prickly-ash, is perhaps the most ornamental member of the genus. It forms a compact, dense shrub or small tree about 8 to 15' high and is clothed with handsome lustrous dark green leaves. Each 3 to 6" long leaf contains 11 to 23 sessile leaflets that average 3/4 to 1 1/2" long. The greenish yellow flowers occur in small 1 to 2" long corymbs in June. The fruits are reddish. The black seeds are ground and used as a pepper in Japan. The stems are armed with 1/3 to 1/2" long, flat spines that occur in pairs at each node. This is a rather handsome plant, the leaves of which may turn yellow in the fall. Northern China, Korea, Japan. Cultivated 1877. Zone 5 to 7.

Zanthoxylum schinifolium Sieb. & Zucc., (zan-thō-zī'lum skī-ni-fō'li-um), Peppertree, is a graceful medium-sized shrub growing 10' or more. The 3 to 7" long leaves are composed of 11 to 21, 3/4 to 1 1/2" long, deep green leaflets. The green-petaled flowers occur in 2 to 4" diameter, flattish corymbs in July–August and are followed by greenish or brownish (red) fruits. The 1/2" long spine is solitary at the node thus differentiating this species from *Z. piperitum* and *Z. americanum*. Leaf blotch and rust were reported on plants in Korea, Japan, Korea, eastern China. Cultivated 1877. Zone 5 to 7.

Zanthoxylum simulans Hance, (zan-thō-zī'lum sim'ū-lanz), Flatspine Prickly-ash, is a graceful, spreading shrub growing 10' or greater in height, although I have seen plants almost tree-like and 15 to 20' high. The stems are armed with broad, flat, 1/4 to 3/4" long spines. The 3 to 5"(9") long leaves are composed of 7 to 11, 1/2 to 2" long, lustrous green leaflets. The greenish flowers occur in 2 to 2 1/2" wide panicles in July and are followed by reddish fruits. Northern and central China. Introduced 1869. Zone 5 to 7.

Zelkova serrata (Thunb.) Mak. — Japanese Zelkova, Keaki

(zel-kō'va ser-rā'ta)

FAMILY: Ulmaceae

LEAVES: Alternate, simple, ovate to oblong-ovate, 1 1/4 to 2" long, or on vigorous shoots to 5" long, 3/4 to 2" wide, acuminate or apiculate, rounded or subcordate at base, sharply serrate with acuminate teeth, with 8 to 14 pairs of veins, dark green and somewhat rough above, glabrous or nearly so beneath; petiole—1/12 to 1/4" long.

BUDS: Ovoid, acutish, with many imbricate, shiny dark brown, broad scales, 1/4" long; diverge at 45° angle from stem.

STEM: Pubescent when young, glabrous at maturity, brown.

BARK: Beautiful, smooth-gray initially, lenticels cherry-like and prominent, finally resembling that of Chinese Elm but usually not as exfoliating.

SIZE: 50 to 80' in height, spread generally less than height; may grow over 120' high in native range.

HARDINESS: Zone (4)5 to 8; successful plants of 'Village Green' on UMaine campus, Orono; species was killed.

HABIT: In youth, a low-branched, vase-shaped tree; in old age maintaining a similar form with many ascending branches.

RATE: Medium, possibly fast in youth, 10 to 12' over a 4 to 6 year period, have seen 3 to 4' of growth on young trees.

TEXTURE: Medium-fine in leaf; medium in winter.

BARK: In youth cherry-like, reddish brown, heavily lenticelled; in old age gray-brown, often exfoliating with a character not unlike that of Chinese Elm, *Ulmus parvifolia*; not as exfoliating as *U. parvifolia*.

LEAF COLOR: Dark green in summer, may bronze or turn off-color in heat of Zone 7 and 8, variable from year to year; possibly the intensity and duration of the summer heat initiates the response; yellow-orange-brown in fall, possibly deep red to reddish purple; in Athens fall color is maximized from early to mid-November.

FLOWERS: Tri-monoecious with male, bisexual, and female flowers in regular sequence on a short shoot; the average number of flowers was 22.6, 2.2, and 3.3, respectively, on each shoot; not showy, flowers in April with the leaves; in Athens have charted full flower as early as February 24 with some years the second week of March.

FRUIT: A small, kidney bean-shaped drupe, about 1/4" across, ripening in fall.

CULTURE: Transplants readily balled-and-burlapped or from a container; prefers moist, deep soil; pH adaptable; once established very wind and drought tolerant; young trees are susceptible to frost; prune in fall; displays reasonable pollution tolerance; in Kansas tests 'Village Green' averaged 11.6" per year over a 9 year period.

DISEASES AND INSECTS: Susceptible to some of the problems which beset the elms; however, resistant to Dutch elm disease; shows good resistance to elm leaf beetle and Japanese beetle; English reference mentioned that it was proving susceptible to Dutch elm disease as well as bacterial canker.

LANDSCAPE VALUE: Very handsome tree because of good foliage, interesting growth habit and handsome bark; well suited to lawns, residential streets, parks, large areas; considered as a replacement for the American Elm but this has not, and will never, come about; there are beautiful specimens at the Arnold, Spring Grove, Cave Hill, Bristol, RI area; does quite well in the South and has been used for streets and urban areas; January 1998 trip to Wichita, KS confirmed good performance there where high pH soils are the norm: some debate about heat tolerance and leaf bronzing in summer; may be cultivar specific but I see extremely vigorous trees in coastal Southeastern cities; visited New Bern, NC in May 2007 and was genuinely impressed with performance; certainly superior to Bradford Pear that is quite common along

streets; the tight, upright vase-shaped branching pattern is the perfect fit between the street and walking areas (i.e. sidewalks); common street tree in Chattanooga, TN.

CULTIVARS:

- Autumn Glow™—Well-proportioned head, good leaf texture, deep purple fall color; John Barbour mentioned that fall color was zilch in his Monroe, GA nursery, now moved south to Hawkinsville, GA.
- City Sprite™ (JFS-KW1, PPAF)—Compact oval to vase-shape outline, densely branched because of short internodes; fine-textured, bright green summer foliage, yellow in fall; 24' by 18'; discovered as a chance seedling by Keith Warren, J. Frank Schmidt & Son Co. introduction.
- 'Goblin'—Dwarf, rounded bush, 3 to 4' high and wide; noted on several occasions, looks like a sheet draped over a child at Halloween; actually a cute obovate bush; difficult to reconcile with *Zelkova*.
- 'Gold Falls'—Newer introduction; graceful, upright, vase-shaped with slightly arching new growth, relatively dense; excellent yellow fall color; 30 to 35' by 15 to 20'; introduced by Charlie's Creek Nursery, Iva, SC.
- 'Goshiki'—Leaves are irregularly cream-marked, -speckled, -splashed, have seen the cultivar several times, leaf variegation pattern is akin to *Osmanthus heterophyllus* 'Goshiki'; reasonably vigorous.
- Green Vase® (PP 5,080)—Vase-shaped with upright arching branches, very vigorous, producing a taller more graceful tree than 'Village Green'; good dark green foliage, orange-brown to bronze-red fall color; 60 to 70' by 40 to 50', grows twice as fast as 'Village Green' as a young tree and 2-year-old trees are 2 to 3 times higher; in this author's opinion the best commercially available form; still believe this is the best and in 1989–90, an allée was planted at the Milliken Arboretum, 18' apart in the row, 24' across, that now constitutes one of the most beautiful plantings anywhere; received the prestigious Styer Award in 1988 from the Pennsylvania Horticultural Society.
- 'Green Veil'—Upright narrow vase shape with gracefully arching shoots producing a soft pendulous effect; does not appear to grow as fast as species, 'Green Vase' and 'Village Green'; beautiful texture, quite dense branching and foliage.
- 'Halka' (PP 5,687)—Have seen 'Green Vase', 'Village Green' and this form in the same nursery with 'Green Vase' and 'Halka' the fastest growing of the three and the most graceful; 50' by 30'; nursery evaluations do not always ring true and plants of the three forms at the Milliken Arboretum, with 18 years of seasoning, reflect the greatness of 'Green Vase', followed by 'Village Green' and then 'Halka'; in Zone 7 'Halka' is looser growing and open, the foliage never, summer and fall, a match for the other two, actually fall color is yellowish; size about 30' by 30' at Milliken.
- 'Illinois Hardy'—Described by Princeton Nursery as surviving a particularly harsh northern Illinois winter that pummeled the other Zelkovas in the vicinity.
- 'Kiwi Sunset'—Spreading tree with semi-pendulous branches, prominent red young stems, and smooth gray bark which exfoliates to reveal orange mosaics when older; leaves, golden yellow, turn orange-red in autumn; how different from 'Ogon', I do not know; listed in John Woods, 2008 catalog.
- Korean Forms—Dense, broad-rounded, full-headed specimens from seed collected in Korea by Drs. Spongberg and Weaver, worthy germplasm for the nursery industry; housed at the Arnold Arboretum.
- 'Low Weeper'—Listed as a lovely weeping form, developing into a true specimen plant; offered by the late Arborvillage, Holt, MO.
- 'Mushashino'—Upright, tightly branched, narrow columnar-vase-shaped habit, dense branches, early-leaving, good-looking plant, possibly more suitable than 'Green Vase' in restricted growing spaces; medium green leaves, yellow in autumn; 45' by 15'; may also go under name 'Iruma Sango', a tree so-named grew in the Raulston Arboretum.
- Myrimar® ('ZSFKF', PP 17,220)—Selected for heat tolerance; 50' by 40'; orange-brown in fall; Zone 5 to 8; see www.southernselections.com.
- 'Ogon' ('Aurea', 'Bright Park')—Rich yellow leaves in spring, yellow-green in summer–fall, striking when leaves first emerge; heat can injure the uppermost leaves in the canopy; stems an amber-yellow color, Newcastle Ale amber in winter; slower growing than species; roots well from cuttings; in *Biochimie Physiologie Pflanzen* 188(2):97–103 (1992); introduced by Barry Yinger I believe originally through Brookgreen Gardens, Wheaton, MD.
- 'Parkview'—A selection with a good vase shape; size similar to species; Dr. Hasselkus reported that it winterkilled in Madison, WI.
- Spring Grove® ('Grovsen')—A handsome vase-shaped form with arching branches that appear slightly stiffer than 'Green Vase' and 'Halka'; the parent tree in Spring Grove, Cincinnati, OH puts other mature zelkovas to shame because of handsome dark green foliage, wine red fall color, excellent branch structure and bark; parent tree was probably 80' with a 50 to 60' spread; has been produced in limited quantities and young trees outplanted in Spring Grove show excellent form; visit confirmed the superiority of 'Spring Grove' to 'Village Green'.
- 'Urban Ruby'—Medium to large tree with rounded head; deeply serrated green leaves turn fiery red in fall; 40 to 50' high
- 'Variegata'—Weak-growing, small-leaved (3/4 to 1 1/2" long) form with a narrow, white rim around the margin of the leaf; might be a good bonsai subject; have observed trees that were reasonably attractive, more than a single 'Variegata' in circulation: at Junker's Nursery, witnessed an improved selection, June 29, 1999.

Village Green™ (PP 2,337)—Selected by Princeton Nurseries, the tree grows more rapidly than ordinary seedlings and develops a smooth, straight trunk; 40' by 40'; the dark green foliage turns a rusty red in fall; much hardier than trees of Japanese origin and is highly resistant to Dutch elm disease and to leaf eating and bark beetles; I studied this selection closely through the years and it is superior to the normal *Z. serrata*; it is vigorous and I recorded as much as 3' of new growth in 1978; interestingly, the fall color was a reasonably good wine-red while every other *Z. serrata* in the Arnold and Boston environs was a golden brown; in laboratory hardiness tests (Dr. Harold Pellett, retired, University of Minnesota), we found that it was not as cold hardy as some seedling material in the Arnold's collections; probably could be grown in Chicago area without too much trouble; was killed at Madison, WI; listed in 1988 Princeton Nursery catalog as one zone hardier than Green Vase®; actually broad, broom head shape with age, denser in form than Green Vase®, still a worthy selection; at Milliken Arboretum, Village Green™ grew slower than Green Vase®, the habit is tighter, broader and not as graceful; Bill Inabinet, Bold Spring Nursery, considered Village Green™ a better performing tree than Green Vase® in Zone 7; both are good, may come down to personal tastes.

Wireless® ('Schmidtlow')—Broad vase-shaped, almost flat-topped, 24' by 36'; medium green foliage, red fall color; tree in the Schmidt Arboretum fits the description to a "T"; 2002 Schmidt introduction.

PROPAGATION: Seeds germinate without pretreatment but percentage is better when stratified at 41°F for 60 days (this was my own personal experience). I have rooted cuttings taken from seedlings with 100% success when treated with 1,000 ppm IBA. Cuttings from older trees root 50 to 60% (70%). Sprouts from 30- to 100-year-old trees rooted in the range of 46 to 83% with 68% average. P-ITB at 5,000 ppm promoted excellent rooting, see *J. Environ. Hort.* 8(2):83–85 (1990). Cultivars are budded on seedling understock. Tissue culture has been successful.

ADDITIONAL NOTES: High quality timber, beautifully grained, used for expensive furniture; extreme durability and strength and used in construction. See *The Plantsman* 11(2):80–86 (1989) for detailed descriptions of *Z. serrata*, *Z. carpinifolia*, *Z. sinica*, *Z. abelicea*, and *Z. xverschaffeltii*. ***Zelkova abelicea*** (Lam.) Boiss. is a spreading shrub with coarsely serrated leaves, about 1" long, that distinguish it from the other species discussed in the *Manual*. Only seen at Hillier. Quite distinct. Flowers small, scented, white. Mountains of Crete. Introduced 1924.

NATIVE HABITAT: Found in rich colluvial soils at the foot of mountains and along the banks of rivers and streams. Japan, Korea, Taiwan, Manchuria. Introduced about 1860, 1862 to America.

RELATED SPECIES:

Zelkova carpinifolia (Pall.) K. Koch — Elm Zelkova, Caucasian Zelkova
(zel-kō'va kār-pī-ni-fō'li-a)

LEAVES: Alternate, simple, ovate or oval, 1 1/2 to 3" long, 3/4 to 1 3/4" wide, acute, rounded or subcordate, coarsely crenate-serrate, obtuse serrations, dark green with scattered hairs above, scabrous, paler and more downy below, 6 to 8 vein pairs; petiole—about 1/8" long.

Zelkova carpinifolia, Elm Zelkova, forms an ovoid or oblong head of rather upright branches, 50 to 75' high, with a short, beech-like trunk. It is a beautiful tree with dark green leaves, 1 1/2 to 3" long, that have 6 to 8 vein pairs. Fall color may approach golden orange depending on weather conditions. The bark is smooth and gray like a beech but flakes with age. There was a magnificent specimen in Kew Gardens, London. 'Verschaffeltii' (*Z. xverschaffeltii* (Dipp.) Nichols.) has driven me taxonomically crazy until a chance encounter at Crathes Castle Garden, Scotland. I enter the garden and say to myself, *Zelkova*, but the leaves are deeply serrate, tree is smaller than typical, i.e., Kew tree, return home, read and two plus two equals this clone. I can now retire-fulfilled. Considered a hybrid between *Z. carpinifolia* and *Z. abelicea* (Lam.) Boiss., leaves 1 to 2 1/2" long, 4 to 8 veins, dark green turning golden in fall. Also listed as a hybrid of *Z. carpinifolia* × *Z. serrata*. Caucasus and southern coastal regions of Caspian Sea. Introduced 1760. Zone 6 to ?

Zelkova schneiderana Hand.-Mazz., (zel-kō'va shnī-dēr-ā'na), Schneider Zelkova, is a virtually unknown entity in the United States but may prove worthy of consideration. A tree in the Morris Arboretum developed excellent wine-red fall color. At first, I thought the tree was *Z. serrata* Village Green™, but the label said otherwise. The habit is akin to *Z. serrata*. The dark green, 1 3/4 to 4" long, 3/4 to 2" wide leaves have 7 to 14 indented vein pairs. Leaves are quite scabrous on their upper surface, much like sandpaper. Supposedly similar to *Z. sinica* and may grow to 100'. Have had correspondence with several individuals who commented on the outstanding fall color. Southwest, central, and eastern China. Introduced 1920. Zone 6 to 8.

Zelkova sinica C.K. Schneid. — Chinese Zelkova
(zel-kō'va sin'i-ka)

LEAVES: Alternate, simple, elliptic to oblong, 1 to 2 1/2" long, 2/3 to 1 1/8" wide, acuminate or apiculate, rounded or broad cuneate, sharply serrate with acute or apiculate teeth, dull dark green and scabrous above, grayish green and pubescent below, 7 to 10 vein pairs; petiole—short, pubescent.

Zelkova sinica, Chinese Zelkova, is smaller (probably 20 to 40' high under cultivation) than *Z. carpinifolia* and *Z. serrata* and sometimes multi-trunked. The dark green leaves have 7 to 10(12) vein pairs. Leaves may turn orange-yellow in autumn. The bark is the handsomest of the genus and on old trunks assumes a rich mottle of gray, orange, and brown. One key difference I noted between this and *Z. serrata* is that the winter buds are more plump and rounded while those of *Z. serrata* are ovoid and pointed. There is a specimen at the Morton Arboretum that indicates the species may be hardier than the Zone 6 rating it was originally given. Cappiello reported cold hardy to Orono, ME. Also fine specimens at the Arnold Arboretum and the old USDA Bamboo farm, Savannah, GA. Have grown seedlings in our Georgia trials but too often crooked in the trunk, slow-growing with little sizzle. I have observed beautiful trees that spur me to keep testing. Central and eastern China at altitudes to 6,500'. Introduced 1907–1908 by E.H. Wilson.

Zenobia pulverulenta (Bartr. ex Willd.) Pollard — Dusty Zenobia
(zen-ō'bi-a pul-vēr-ū-len'ta)

FAMILY: Ericaceae

LEAVES: Alternate, simple, semi-evergreen to deciduous, oval to oblong, 1 to 3" long, obtuse or acutish, usually rounded at base, entire to serrulate-crenate, glabrous and covered more or less with a glaucous bloom on both surfaces, appearing green, gray-green to bluish green to glaucous blue.

STEM: Glabrous, glaucous, bloomy, often arching.

Zenobia pulverulenta is a 2 to 3'(6') high, gracefully arching shrub. A 6 to 8' high colony grew at Furzey Garden, Hampshire. The leaves are particularly attractive and in fall turn yellowish with a tinge of red, bronze to purple. The 3/8" broad, white, anise-scented, narrow bell-shaped flowers occur on slender, nodding, 3/4" long stalks in axillary clusters during May–June. Requires acid, moist, well-drained soil for best growth. Full sun to partial shade. Often available from native plant nurseries. Some nurseries offer selected dusty blue foliage forms and have no trouble rooting them. Great planting of green, blue-green, and bluish foliaged seedlings in a sweep by Bussey Brook in the Arnold Arboretum. Terrific native plant for wet soil areas. 'Raspberry Ripple' is a green foliaged form that develops good autumn color, flowers like the species, listed in Heronswood 1998 catalog and have observed in bronze-red fall color at the Raulston. Flowers are large, white and marked with rose-red staining. Not superior to 'Woodlanders Blue', a glaucous, powder-blue foliage selection with red-purple fall color. Fall color develops late, magnificent on December 22, 2005 at the Atlanta Botanical Garden. This latter form is a knockout plant for foliage effect. Requires even moisture under cultivation or will languish. A f. *nitida* (Michx.) Forn. with green leaves is listed but in my opinion of no real taxonomic merit. Also listed are 'Blue Skye' and 'Misty Blue', I assume referring to foliage color. North Carolina to Florida. Introduced 1801. Zone 5 to 9. Injured, on occasions severely, in Orono, ME.

Ziziphus jujuba Mill. — Chinese Date (The generic name is also spelled *Zizyphus*)
(ziz'i-fus jō-jō'ba)

FAMILY: Rhamnaceae

LEAVES: Alternate, simple, oval, ovate to ovate-lanceolate, 1 to 2 1/2" long, acutish or obtusish, oblique, 3-nerved at base, crenate-serrulate, lustrous dark green, glabrous, firm; petiole—1/8 to 1/4" long.

STEM: Glabrous, flexuose, with paired spines at the nodes, the larger straighter ones to 1 1/4", the shorter—decurved.

Ziziphus jujuba is a rather unique large shrub or small tree with handsome lustrous green foliage, rounded outline, and 15 to 20'(25') ultimate size. In 1983, I saw a 40' high tree on United States Capitol grounds with blocky, persimmon-like bark. This is now the National Champion at 61' by 51'. Leaves may turn good yellow in fall. The small, 1/4" diameter, fragrant (grape soda), yellowish flowers occur

2 to 3 together from the leaf axils of the current season's growth. The edible fruits, which I have been fooled by on previous occasions, are plum-like to egg-shaped in outline, 1/2 to 1" long and generally listed as dark red to black when ripe. Ripen about mid September in Athens. Grown in China for over 4,000 years and one of the five most popular fruits there. A former student's, Mr. Mark Callahan, greatest joy was trying to ruin my Monday by attacking me with some unusual plant from the vicinity of Hazelhurst, GA. The fruits he brought were more brownish than red or black. The species will grow in any well-drained, acid, alkaline, and droughty soil and based on observations at Tennessee Valley Nursery, Winchester, TN is hardy to -15°F. An old planting at Bernheim Arboretum is kind of limping along after exposure to -24°F. Obviously this is a plant for the collector and will never find its way into the gardening mainstream. However, at least four individuals wanted to know why it was left out of the earlier editions. Well, I couldn't take the pressure and relented. Happy Chinese Dating. Seeds are the usual means of propagation and apparently require 3 months warm/3 months cold for best germination. June cuttings were rooted at 85% using 250 ppm IBA + 500 ppm NAA. Tissue culture has been successful. Cultivars are grafted to seedling understocks. 'Inermis' (var. *inermis* Rehd.) is thornless. 'Lang' is precocious and bears 1 1/2 to 2" long, pear-shaped fruits while 'Li' has 2" long, rounded fruits. 'Sherwood' produces large, sweet fruit that does well in the deep South. Dr. Mark Reiger planted 'Lang' and 'Li' in the edible ornamentals test plots at UGA's Horticulture Farm. I watched them for years, sampled the fruit (taste quite tasteless, like a water chestnut, just not crunchy), noted suckering like sumac, and was poked by thorns. Grew in the worst soil at the Farm where even weeds couldn't take hold. Fruit is set without pollination and there are no serious insect, disease or nematode pests in the United States. Have read about 'So' with twisted, spiraling branches; fruit is listed as sweet. Available from Burnt Ridge Nursery and Orchards, Onalaska, WA. Southeastern Europe to southern and eastern Asia. Introduced about 1640. Zone 6 to 9.

BIBLIOGRAPHY

Many new references, published since the 1998 edition, are included in the Bibliography. However, others are meshed with their respective text, especially the generic treatments. For example, there are six *Hydrangea* books now included. Dr. Clifford Parks, Gao Jiyin and Yuequiang Du produced a self-published *Camellia* species text, *Collected Species of the Genus Camellia, an Illustrated Outline* with magnificent photographs. Cited in the bibliography, it is a lost treasure; up-front and visible, the reader may opt to search it out.

No easy way to make a Bibliography meaningful except to advocate the readers chase some of the books during their learning journeys. Remarkable how many books have been penned about trees and shrubs. Only so many ways to describe a Sugar Maple, *Acer saccharum*, and then redundancy takes over. The flavorful, spicy, pithy comments by the authors bring the Sugar Maple to life. I always anticipate the next woody plant book, thin or tome-like, as long as it provides a unique perspective.

GLOSSARY OF TAXONOMIC TERMS COMMONLY EMPLOYED IN THE IDENTIFICATION OF WOODY PLANTS

- a-**: prefix indicating not or without.
- abortive**: defective, barren, not developed.
- abruptly pinnate**: without a terminal leaflet.
- abscission**: the separating of a leaf from a self healing, clean-cut scar.
- acaulescent**: stemless or apparently so. Ex: *Taraxacum*, *Dodecatheon*, *Primula*.
- accessory buds**: those found beside or above the true bud at a node.
- accessory fruit**: one whose conspicuous tissues have not been derived from those comprising the pistil of the fl.
Ex: in strawberry, (*Fragaria*) the fleshy part of the fr. is of receptacular and not of pistillate origin. An accessory fr. may or may not also be an aggregate fr. (it is so in the strawberry and not so in the banana).
- accessory parts of a flower**: the petals and sepals.
- achene**: a dry indehiscent one-seeded fruit. Ex: fr. of members of the Compositae.
- acicular**: needle-shaped. Ex: lvs. of *Pinus*, spines of some cacti.
- acorn**: the fruit of oaks, a thick walled nut with a woody cup-like base.
- actinomorphic**: of regular symmetry, applied to perianth whorls, as opposed to zygomorphic.
- aculeate**: prickly.
- acuminate**: having an apex whose sides are gradually concave and tapering to a point.
- acute**: having an apex whose sides are straight and taper to a point.
- adherent**: a condition existing when two dissimilar organs touch each other (sometimes seemingly fused) but not grown together.
- adnate**: fused with unlike parts, as in the fusion of a filament to a petal.
- adventitious**: arising from an unusual or irregular position.
- aerial rootlets**: those produced above ground, especially as in climbing organs of a vine.
- aestivation**: the arrangement of floral parts (especially sepals and petals) in the bud.
- aggregate flower**: a flower heaped or crowded into a dense cluster.
- aggregate fruit**: one formed by the coherence or the connation of pistils that were distinct in the flower (as in *Rubus*); when the pistils of separate flowers (as in mulberry) make up the fr. it is designated as a multiple fruit.
- akene**: a small dry indehiscent fruit with one seed free inside the thin pericarp; also spelled achene.
- alternate**: an arrangement of leaves or other parts not opposite or whorled; parts situated one at a node, as leaves on a stem: like parts succeeding each other singly with a common structure.
- ament**: see *catkin*.
- amplexicaul**: encircling the stem.
- anastomosing**: netted, applied to the veins of a lf.; the marginal reticulations closed.
- androecium**: stamens of a fl. as a unit.
- anemophilous**: describes flowers that are pollinated by wind.
- angiospermous**: having seeds borne within a pericarp.
- angular**: of pith; not rounded in cross section.
- annual**: maturing and living one season only.
- annular**: shaped like a ring.
- anterior**: on the front side, away from the axis, toward the subtending bract.
- anther**: pollen-bearing part of a stamen, borne at the top of a filament, or sessile.
- anthesis** (an-thee-sis): that period of fl. development when pollen is shed from the anther; also used to designate the act of flowering or the time of fl. expansion.
- apetalous**: without petals. Ex: fls. of grasses.
- apex**: the tip or terminal end.
- apical**: describes the apex or tip.
- apiculate**: ending abruptly in a short pointed tip.
- apocarpous**: having separate carpels; frequently applied to a gynoeceum of several pistils.
- apophysis**: that part of the cone scale that is exposed when the cone is closed.
- appressed**: pressed close to the stem, not spreading.
- arboreal, arboreous**: treelike or pertaining to trees.
- arching**: curving gracefully.
- arcuate venation**: pinnate, with the secondary veins curving and running parallel to the margin.
- areole**: small pit or raised spot, often bearing a tuft of hairs, glochids, or spines.
- aril**: a fleshy appendage of the seed, usually a fleshy seedcoat.
- aristate**: bearing a stiff bristle-like awn or arista, or tapered to a very slender stiff tip. Ex: awns of many grasses, apices of many calyx-teeth.
- armed**: provided with a sharp defense such as thorns, spines, prickles or barbs.

aromatic: fragrantly scented, at least if broken or crushed.

articulate: having nodes or joints where separation may naturally occur.

ascending: curving indirectly or obliquely upward. Ex: branches of *Taxus canadensis*.

assurgent: rising at an angle, not straight upwards.

attenuate: showing a long gradual slender taper; usually applied to apices, but equally appropriate for bases of leaves, petals, etc.

auriculate: bearing ear-like appendages, as the projections of some leaf and petal bases.

awl-shaped: tapering to a slender stiff point.

awn: a bristle-like appendage.

axil: belonging to the axis. See *placentation*.

axillary: in the axil.

axis: the main stem or central support of a plant.

baccate: pulpy, fleshy.

barbed: bristles, awns, etc. provided with terminal or lateral spine-like hooks that are bent sharply backward.
Ex: pappus on fruits of beggar's ticks.

bark: a dead outer protective tissue of woody plants, derived from the cortex. Varies greatly in appearance and texture; often including all tissue from the vascular cambium outward.

basal: pertaining to the extremity of an organ by which it is attached to its support; said of lvs. when at base of plant only. See *rosette*.

basifixed: attached basally as ovules or anthers.

beak: a long prominent point. Ex: on lettuce (*Lactuca*) or dandelion (*Taraxacum*) frs.

beaked: ending in a point, especially on fruits.

bearded: having long hairs.

berry: a fleshy indehiscent pulpy multi-seeded fr. resulting from a single pistil. Ex: tomato.

bi-: prefix indicating twice or doubly.

biennial: of two seasons duration, normally flowering, fruiting and dying the second growing season from time of seed germination.

bifid: two-cleft, as in apices of some petals and leaves. Ex: petals of some *Lychnis* or leaves of *Bauhinia*.

bifurcate: forked, as some Y-shaped hairs.

bilabiate: two-lipped, often applied to a corolla or calyx: each lip may or may not be lobed or toothed.
Ex: corolla of snapdragon (*Antirrhinum*) and most members of the mint family (Lamiaceae).

bipinnate: twice pinnate.

bisexual: stamens and pistil present in the one fl.

biternate: twice ternate; a structure basically ternate, but whose primary divisions are again each ternate.
Ex: lvs. of some columbines (*Aquilegia*) and meadow-rues (*Thalictrum*).

bladder-like: inflated, empty with thin walls.

blade: the expanded part of lf. or petal; lamina.

bloom: a waxy coating found on stems, leaves, flowers and fruits, usually of a grayish cast and easily removed.

bole: stem of a tree.

boss: a raised usually pointed projection.

bract: a much-reduced lf., often scale-like and usually associated with a fl. or infl.

branch: one of the coarser divisions of a trunk or main branch.

branchlet: smaller, a division of the branch.

bristle: a stiff hair.

broad-elliptic: wider than elliptic.

broad-ovate: wider than ovate.

bronzing: turning a metallic bronze or coppery color, especially of foliage after a winter.

bud: a structure of embryonic tissues, which will become a leaf, a flower, or both, or a new shoot. Especially the stage in which a growing point spends the winter or a dry season. May be naked or enclosed in scales.

bud scale: a modified leaf or stipule (there may be one, a few, or many) protective of the embryonic tissue of the bud.

bud scale scar: the mark left by the sloughing off of the bud scale.

bulb: a modified underground stem comprised of shortened central axis surrounded by fleshy scale-like lvs.

bulbil: small bulbs arising around parent bulb.

bulblet: small bulbs arising in leaf axils.

bullate: with the surface appearing as if blistered between the veins. Ex: Savoy cabbage.

bundle scar: seen in the leaf scar, the broken ends of the woody vascular strands that connected the leaf and the stem.

bur: any rough or prickly seed envelope.

burl: a knot or woody growth of very irregular grain.

bush: a low several stemmed shrub with no single trunk.

- caducous:** falling off early or prematurely.
- calcarate:** having a spur.
- calcicole:** a plant growing best on limey soils.
- callus:** a hard protuberance, or the new tissues formed in response to a wound.
- calyx:** the outer set of perianth segments or floral envelope of a flower, usually green in color and smaller than the inner set.
- campanulate:** bell-shaped.
- cane:** a long woody pliable stem rising from the ground.
- canescent:** having a gray hoary pubescence.
- capillary:** hair-like; very slender.
- capitate:** headlike, in a dense rounded cluster.
- capsule:** a dry dehiscent fruit produced from a compound pistil. Ex: fruit of a tobacco, *Catalpa*, *Dianthus*.
- carinate:** keeled; with longitudinal ridge or line.
- carpel:** one of the foliar units of gynoecium. See *pistil*.
- carphophore:** elongated axis bearing a gynoecium and projecting between the carpels.
- caryopsis:** the fruit of members of the grass family; not basically distinct from an achene.
- castaneous:** dark brown.
- catkin:** a spike-like infl. comprised of scaly bracts subtending unisexual fls., often somewhat flexuous and pendulous but not necessarily so. Ex: infl. of willows (*Salix*) and poplars (*Populus*).
- caudate:** bearing a tail-like appendage. Ex: spadices of some aroids.
- caulescent:** having an evident leaf-bearing stem above ground.
- cauliflorous:** flowering from the trunk or main branches directly or on short specialized spurs.
- cauline:** of or belonging to the stem.
- ceriferous:** waxy.
- cernuous:** drooping or nodding.
- cespitose:** growing in tufts or dense clumps.
- chaff:** dry, thin, membranous bract, particularly those subtending the fls. of the Compositae.
- chaffy:** covered with small thin dry scales or bracts.
- chalaza:** basal part of ovule, where it is attached to the funiculus.
- chambered:** of pith, divided into empty horizontal chambers by cross partitions.
- channeled:** grooved lengthwise.
- chartaceous:** of papery or tissue-like texture.
- ciliate:** marginally fringed with hairs, often minutely so and then termed "ciliolate."
- cinereous:** ash colored.
- circinate:** rolled coil-wise from top downward. Ex: unopened fern fronds.
- circumscissile:** opening or dehiscing by a line around the fr. or anther, the top (valve) coming off as a lid. Ex: fr. of *Portulaca* or *Plantago*.
- cladophyll:** a flattened, foliaceous stem having the form and function of a leaf, but arising in the axis of minute bract-like often caducous true leaf. Ex: the so-called leaves of *Ruscus* and *Asparagus*.
- clasping:** a stalkless leaf, with the base partly surrounding the stem.
- clavate:** club-shaped, as a baseball bat.
- claw:** the constricted petiole-like base of petals and sepals of some flowers. Ex: petals of flowers of mustard family, of *Cleome*.
- cleft:** divided to or about the middle into divisions.
- cleistogamous:** describes a small, closed self-fertilized flower, usually near the ground.
- climbing plant:** one which raises its foliage by supporting itself on surrounding objects, by twining stem or tendrils, grasping rootlets, or scrambling.
- clone:** a group of plants derived vegetatively from one parent plant, identical to each other and to the parent.
- close bark:** not broken up or scaly.
- clustered:** of leaves, crowded so as not to be clearly opposite or alternate, also said of whorled condition.
- coalescent:** two or more parts united.
- coarse (texture):** consisting of large or rough parts.
- coherent:** two or more similar parts or organs touching one another in very close proximity by the tissues not fused. Ex: the two ovaries of asclepiadaceous flowers. (By some the term treated as if synonymous with connate.)
- collateral buds:** accessory buds to either side of the true lateral bud at a node.
- columella:** the carphophores in umbellifer fruits.
- column:** the structure formed by union of filaments in a tube (as in mallows) or of the filaments and style of orchids.
- commisure:** the edge or face of two adjoining structures.
- comose:** tufted with hairs. Ex: milkweed seeds.
- compact:** arranged in a small amount of space, dense habit.
- complete flower:** one which has corolla, calyx, stamens and one or more pistils.

composite: compound.

compound leaf: a leaf of two or more leaflets, in some cases (*Citrus*) the lateral leaflets may have been lost and only the terminal lft. remain. *Ternately compound* when the lfts. are in 3's; *palmately compound* when three or more lfts. arise from a common point to be palmate (if only three are present they may be sessile); *pinnately compound* when arranged along a common rachis or if only three are present at least the terminal lft. is petioled; *odd-pinnate* if a terminal lft. is present and the total number of lfts., for the lf. is an odd-number; *even-pinnate* if no terminal lft. is present and the total is an even number.

compound pistil: a pistil comprised of two or more carpels. The number of cells or locules within the ovary may or may not indicate the number of carpels. An ovary having more than one complete cell or locule is always compound, but many one-celled ovaries are compound also. A pistil having a one-celled ovary, but more than one placenta or more than one style or more than one stigma, or any combination of these duplicities, may be presumed to be compound insofar as taxonomic considerations are concerned.

compressed: flattened from the sides.

concave: curved like the inner surface of a sphere.

conduplicate: folded together lengthwise.

cone: a coniferous fruit, having a number of woody, leathery, or fleshy scales, each bearing one or more seeds, and attached to a central axis.

conelet: a young, immature first season cone, in the pines.

conical: cone shaped, as the young form of many spruces.

confluent: blending together, not easily distinguishable as separate.

coniferous: cone bearing.

connate: like parts fused together into one, fused into a tube. Ex: filaments of a mallow androecium, or anthers of a Composite flower.

connective: the tissues between the two anthers of a stamen, often much elaborated when the anther cells are separated. Ex: *Salvia*.

connivent: a synonym of coherent.

constricted: squeezed or compressed as if by shrinking or tightening.

continuous pith: solid and without interruption.

convex: curved like the outer surface of a sphere.

convolute: rolled up lengthwise; in flower buds when overlapping of one edge of a perianth segment by the next while the other margin is overlapped by its preceding member.

coppice: growth arising from sprouts at the stump, bushy.

cordate: heart-shaped, with a sinus and rounded lobes; properly a term applied only to bases of leaves and bracts, but frequently employed to designate a structure of ovate outline and heart-shaped base.

coriaceous: of leathery texture. Ex: *Buxus* lf.

corky ridges: elongated warts or strips of soft springy wood.

corm: a solid bulb-like underground stem not differentiated into scales, often depressed-globose in form, bearing scale-like buds on surface, usually tunicated. Ex: *Gladiolus*, *Crocus*.

cormel: small corm arising from base of parent corm.

corolla: the usually petaloid, inner whorl or floral envelopes; when the parts are separate and distinct they are petals and the corolla is said to be *polypetalous*; when connate in whole or in part the distal parts are teeth, lobes, divisions, or segments and the corolla is said to be *gamopetalous*.

corona: a crown; an appendage or extrusion that stands between the corolla and stamens; an outgrowth of perianth tissue in the "cup" of *Narcissus*, or of the androecium in the milkweeds.

corymb: a more or less flat-topped indeterminate infl. whose outer fls. open first. Ex: *Hydrangea*, some verbenas.

costate: having longitudinal ribs or veins.

cotyledon: the primary leaves of the embryo, present in the seed.

creeping: running along at or near the ground level and rooting occasionally.

cremocarp: a dry dehiscent 2 seeded fruit of the Umbelliferae (Apiaceae), each half a mericarp.

crenate: rounded teeth on mgn. Ex: lvs. of some *Coleus*.

crenate-serrate: having a mixture of blunt and sharp teeth.

crenulate: having very small rounded teeth.

crested: with an elevated and irregular or toothed ridge; found on some seeds or some floral parts.

crisp-hairy: with kinky hair or tomentum.

crown: the upper mass or head of a tree, also a central point near the ground level of a perennial herb from which new shoots arise each year.

cruciform: cross shaped.

cucullate: hooded.

culm: stem of grasses and sedges.

cultigen: a plant arising through domestication and cultivation.

cultivar: a cultivated variety; see Classification and Nomenclature section.

cultivated: maintained by man.

- cuneate**: wedge-shaped with essentially straight side, the structure attached at the narrow end.
- cuspidate**: with an apex somewhat abruptly and concavely constricted into an elongated sharp-pointed tip.
- cuticle**: an outer film of dead epidermal cells, often waxy.
- cyathium**: the infl. characteristic of *Euphorbia*, the fls. condensed and congested within a bracteate envelope, emerging at anthesis.
- cymbiform**: boat-shaped.
- cyme**: a more or less flat-topped determinate infl. whose outer fls. open last. Ex: elderberry (*Sambucus*).
- cymose**: of or arranged on cymes.
- cymule**: a diminutive cyme. Ex: *Armeria*.
- deciduous**: falling off, as lvs. of a tree.
- decompound**: more than one compound.
- decumbent**: reclining on ground with tip ascending.
- decurrent**: extending down the stem.
- decussate**: with alternating pairs at right angles to each other, as pairs of opposite lvs. on a stem.
- deflexed**: synonym of reflexed.
- defoliation**: casting off or falling off of leaves.
- dehiscent**: splitting open, the sides or segments of the splitting organ usually termed valves; *loculicidally* dehiscent when the split opens into a cavity or locule, *septicidally* dehiscent when at point of union of septum or partition to the side wall, *circumscissilely* when the top valve comes off as a lid. *Poricidally* when by means of pores whose valves are often flap-like. The term is commonly applied to anthers or seed pods.
- deliquescent**: the primary axis or stem much branched. Ex: branching of an elm tree.
- deltoid**: triangular.
- dense**: crowded together, thick, compact.
- dentate**: having marginal teeth whose apices are perpendicular to the margin and do not point forward.
- denticulate**: slightly or minutely dentate.
- denuded**: naked through loss of covering.
- depressed**: flattened, as if compressed somewhat.
- determinate**: said of an inflorescence when the terminal flower opens first and the prolongation of the axis is thereby arrested.
- di-**: prefix indicating two.
- diadelphous**: in two sets, applied to stamens. In many legumes the androecium is comprised of 10 stamens: 9 in one set, 1 in the other.
- diandrous**: having an androecium of two stamens.
- diaphragmed pith**: having horizontally elongated cells with thickened walls spaced throughout the pith like the rungs of a ladder.
- dichlamydeous**: having both a corolla and a calyx.
- dichotomous**: forked in pairs.
- diclinous**: with unisexual flowers.
- dicot**: angiospermous plant having two cotyledons.
- didynamous**: in two pairs of different length.
- diffuse**: loosely or widely spreading, an open form.
- digitate**: palmate.
- dimorphic**: having two forms.
- dioecious**: having unisexual fls., each sex confined to a separate plant, said of species.
- disarticulate**: to fall away leaving a clear cut scar.
- discoid**: having only disk fls. as an infl. of a member of the Compositae family.
- disk**: (1) a glandular elevation about the base of a superior ovary; (2) the flattened receptacle of the infl.; (3) a flattened extremity as a stigma or as on the tendrils of some climbing vines.
- disk flower**: the tubular fl. in the center of the usual Composite infl. Ex: daisy, aster.
- disposed**: arranged.
- dissected**: divided in narrow, slender segments.
- distal**: toward the apex, away from the base.
- distichous**: two-ranked, with lvs., lfts. or fls. on opposite sides of a stem in the same plant.
- distinct**: separate, not united with parts of like kind. Compare with "free".
- diurnal**: blossoms opening only during the day.
- divaricate**: spreading very wide apart.
- divergent**: spreading broadly.
- divided**: separated to the base into divisions.
- dormant**: in a restive or non vegetative state, especially a winter condition.
- dorsal**: the back or outer surface.
- dorsiventral**: referring to a front-to-back plane.
- dotted**: describes the underside of a leaf having a pattern of spots or hair glands visible.

double flower: one with more than the usual number of petals, colored sepals or bracts.

double serrate: serrations bearing minute teeth on margins.

doubly compound: bi-pinnate.

doubly crenate, dentate, or serrate: having small teeth of the given kind within the larger ones.

downy: pubescent with fine soft hairs.

drooping: hanging from the base, suggesting wilting.

drupaceous: drupe-like.

drupe: a fleshy indehiscent fr. whose seed is enclosed in a stony endocarp. Ex: date, cherry.

drupelet: a small drupe. Ex: raspberry.

duct: generally, a water conducting tube, also a canal through the wood carrying resin, latex or oil.

dwarf: an atypically small plant.

dwarf shoots: spur shoots.

ebracteate: without bracts.

echinate: with stout bluntish prickles.

eglandular: without glands.

ellipsoid: three dimensional shape of ellipse, football shaped.

elliptic-oblong: a shape between the two forms.

elliptical: having the outline of an ellipse, broadest at middle and narrower at each end.

elongate: lengthened.

emarginate: with a shallow notch at the apex.

emergences: appendages other than hairs.

endemic: confined to a small geographic area.

endocarp: the inner layer of the pericarp.

ensiform: sword-shaped.

entire: having a margin without teeth or crenations.

entomophilous: describes flowers that are pollinated by insects.

ephemeral: persisting for one day only, of short duration. Ex: fls. of *Tradescantia*.

epidermis: the outer superficial layer of cells.

epigynous: borne on the ovary; said of the fl. when the ovary is inferior, or of stamens when apparently borne on the gynoecium.

epitrophic: more nourished and developed on the upper side.

equitant: overlapping in two ranks. Ex: lvs. of *Iris*.

erect: upright habit of growth.

erose: having a margin appearing eroded or gnawed; of a jaggedness not sufficiently regular to be toothed.

Ex: leaf apices of the fish-tail palm (*Caryota*).

espalier: any plant trained lattice fashion in one plane.

established: growing and reproducing without cultivation.

estipulate: without stipules.

evanescent: describes veins grown very faint near the margin.

even-pinnate: results in a lack of the terminal leaflet, since each one is paired.

evergreen: having green foliage throughout the year.

excavated: describes pith which is hollow between the nodes.

excurrent: extending beyond the margin or tip. Ex: awns of some grasses.

exfoliate: to peel off in shreds or thin layers, as bark from a tree.

exotic: foreign, not naturalized.

exserted: projecting beyond, as stamens beyond a corolla.

extipulate: without stipules.

extorse: facing outward from the center; in the case of anthers, dehiscing outward; a character most accurately determined by a cross-section of the anther.

falcate: sickle-shaped.

falls: outer whorl of perianth segments of an iridaceous fl., often broader than the inner and, in some *Iris*, drooping or flexuous.

farinaceous: with a powdery or mealy coating.

fasciated: abnormally much flattened, and seemingly several units fused together.

fascicle: a close cluster. Ex: lvs. of white pine.

fastigiate: branches erect and close together.

felty: having compressed matted fibers.

fenestrate: perforated with opening or with translucent areas. Ex: lvs. of *Monstera deliciosa*.

ferrugineous: rust colored.

fertile: capable of producing fruit and seed.

fibrous: having long narrow shreds or flakes.

filament: that portion of a stamen comprising the stalk.

filamentous: thread-like.

filiform: long and very slender; thread-like.

fimbriate: fringed.

fine texture: consisting of small rather delicate parts.

firm bark: close, not broken into loose or shaggy parts.

fissured bark: torn lengthwise, with vertical furrows.

fistulose: hollow and cylindrical.

fistulous: describes a hollow stem with excavated pith.

flabellate: fan-like.

flaccid: limp.

flaking: shreddy, with shorter fragments.

flat: a low horizontal habit of growth.

fleshy: applied to a fruit somewhat pulpy or juicy at maturity, as opposed to a dry hard or papery fruit.

flexuous: wavy.

floccose: having surface with tufts of soft woolly hair, often rubbing off easily.

floret: technically a minute flower; applied to the flowers of grasses and Composites.

flower: an axis bearing one or more pistils or one or more stamens or both: when only the former, it is a *perfect flower* (i.e. bisexual or hermaphroditic). The androecium represents a series or whorls, derived from a spiral condition adjoining the pistil. When this perfect flower is surrounded by a perianth represented by two floral envelopes (the inner envelope comprising the corolla, the outer the calyx), it is a *complete flower*.

flower scar: marks remaining after the abscission of the flower parts.

fluted: having rounded lengthwise ridges.

foliaceous: leaf-like in color and form.

foliage: leaves.

-foliate: -leaved.

-foliolate: -leafleted.

follicle: a dry dehiscent fruit opening only along one suture and the product of a single carpel (simple ovary).

Ex: peony, columbine, milkweed.

forma: a subdivision of a species which occurs occasionally in the wild, seldom breeds true, and does not develop a natural population or distribution.

foveola: a pit.

fragmented: not continuous, especially of vascular bundle scars.

free: separate in that it is not joined to other organs; as petals free from calyx or calyx free from capsule. Contrast with "distinct".

free-central: *see placentation*.

fringed: ciliate with glands or scales rather than hairs.

frond: a leaf, once applied only to leaves of ferns but now to leaves of palms also.

fruit: technically a ripened ovary with its adnate parts, the seed-containing unit characteristic of all Angiosperms. The term is also employed loosely for all similar structures as the "fruit" of a Cycad which in reality is a naked seed or the "fruit" of the Blue Cohosh (an Angiosperm) which also is a naked seed: all are functionally fruiting structures.

fruticose: shrubby, in sense of stems being woody.

fugacious: falling or withering very early.

fulvous: tawny, a dull grayish yellow color.

funiculus: the stalk by which an ovule is attached to the ovary wall.

funnelform: the tube gradually widening. Ex: corolla of morning-glory.

furcate: forked.

furrowed: having longitudinal channels or grooves.

fuscous: grayish brown.

fusiform: spindle-shaped; tapering to each end from a smaller mid-section.

galea: a helmet. Ex: *Aconitum*.

gamopetalous: the petals united, at least at base, to form a corolla of one piece; the corolla coming off from the fl. as a single unit.

geniculate: bent like a knee.

genus: a group of species possessing fundamental traits in common but differing in other lesser characteristics.

gibbous: swollen on one side, usually basally. Ex: snapdragon corolla.

glabrate: becoming glabrous with maturity, but as seen under a lens is noted to be not quite so prior to maturity.

glabrous: not hairy. Note: a glabrous surface need not be smooth, for it may be bullate or rugose.

gland: a general term applied to oil-secreting organs, or sometimes an obtuse projection or a ring at base of a structure.

glandular: bearing glands.

glandular-pubescent: glands and hairs intermixed.

glandular-punctate: see *punctate*.

glaucouscent: slightly glaucous.

glaucous: covered with a waxy bloom or whitish material that rubs off readily. Ex: the bloom on many sorts of grape.

globose: having a round or spherical shape.

globular: circular.

glochid: a minute barbed spine or bristle. Ex: the components of the tawny hair-like tufts on many species of *Opuntia*.

glomerate: in dense or compact clusters, usually applied to flowers.

glossy: shining, reflecting more light than if lustrous.

glume: a stiff chaff-like bract, usually applied to the two empty bracts at base of grass spikelets.

glutinous: sticky.

granular: minutely roughened.

grooved: marked with long narrow furrows or channels.

ground cover: a plant that grows near the ground densely, and spreads.

gum: a fluid sticky resin.

gymnospermous: plant bearing naked seeds without an ovary.

gynoecium: collectively the female element of a fl.; a collective term employed for the several pistils of a single fl. when referred to as a unit; when only one pistil is present the two terms are synonymous.

gynophore: a stalk bearing a pistil above point of stamen attachment. Ex: *Cleome*.

habit: the general aspect or mode of growth of a plant.

habitat: the type surrounding in which a plant grows.

hair: superficial outgrowth, trichome.

hairy: pubescent with longer hairs.

hardened: conditioned by various factors to withstand environmental stresses; contrast with succulent growth which is very vulnerable.

hardy: capable of enduring winter stresses.

hastate: having the shape of an arrow-head and the basal lobes pointed outwards at or nearly at right angles to the mid-rib.

head: a short dense infl. of variable form, as in Compositae (daisy) family, *Eryngium*, or many clovers.

helicoïd: spiraling like a snail shell.

herb: a plant dying to the ground at the end of the season; one whose aerial stems are soft and succulent without appreciable parenchymatous xylem tissue; a plant not woody in texture.

herbaceous: having no persistent woody stem above ground.

herbage: vegetative parts of an herb.

hermaphrodite: bisexual.

hesperidium: a fleshy berry-like fr. with hard rind and definite longitudinal partitions. Ex: orange.

heterogamous: bearing two kinds of flowers.

heterogeneous: not uniform in kind of flowers.

hidden bud: bud covered by the petiole base and therefore inconspicuous.

hilum: the scar on a seed marking its point of attachment.

hip: fruit of the rose.

hippocrepiform: horseshoe-shaped.

hirsute: pubescent with coarse or stiff hairs.

hirtellous: minutely hirsute.

hispid: with stiff or bristly hairs.

hispidulous: minutely hispid.

hoary: with a close white or whitish pubescence.

hollow: describes pith with a central cavity.

homogamous: bearing only one kind of flower.

homogeneous: all of one kind and texture, continuous pith.

hooked: bent like a hook, having a hook.

horizontal: with broad faces parallel to the ground.

humifuse: spreading over the ground.

husk: outer covering of the seed or fruit.

hyaline: translucent when viewed in transmitted light.

hybrid: plant resulting from a cross between two or more other plants which are more or less alike.

hydrophyte: an aquatic plant.

- hypanthium:** the cup-like “receptacle” derived from the fusion of perianth parts and on which are seemingly borne the stamens, corolla, and calyx. Ex: fuchsia, plum.
- hypocrateriform:** *see salverform*.
- hypogynous:** borne on the torus or receptacle, beneath or at base of ovary; said of stamens, petals or calyx when the ovary is superior or above their point of attachment.
- hypotrophic:** more nourished and developed on the under side.
- imbricated:** overlapping, as shingles on a roof.
- imperfect flower:** one which lacks either stamens or pistils.
- impressed:** bent inward, furrowed as if by pressure.
- incised:** cut by sharp and irregular incisions more or less deeply, but intermediate between toothed and lobed.
- included:** not protruding as stamens not projecting beyond a corolla; opposed to exerted.
- incomplete flower:** one which lacks any one or more of these parts: calyx, corolla, stamens, and pistils.
- incumbent:** having cotyledons which within the seed lie face to face with the back of one lying against the hypocotyl; anthers are incumbent when turned inwards.
- incurved:** bent into an inward curve.
- indehiscent:** not opening regularly, as a capsule or anther.
- indeterminate:** said of those kinds of infl. whose terminal fls. open last, hence the growth or elongation of the main axis is not arrested by the opening of first flowers.
- indigen:** plant native and original to a region.
- indumentum:** with a generally heavy covering of hair: a general term without precise connotation.
- indurate:** hardened.
- indusium:** the epithelial excrescence that, when present, covers or contains the sporangia of a fern when the latter are in sori.
- inferior:** beneath, below; said of an ovary when situated below the apparent point of attachment of stamens and perianth; a fl. having such an ovary is said to be epigynous.
- inflated:** bladder like, loose and membranous about the seed.
- inflorescence:** the method of flower-bearing; the disposition of flowers on the axis (or axes).
- infundibular:** funnel-shaped.
- inner bark:** cortical tissues inside the protective outer layers but outside the wood.
- internode:** the part of an axis between two nodes.
- interrupted:** not continuous, smaller parts or lack of parts between normal ones.
- introduced:** brought intentionally from another region for purposes of cultivation.
- introrse:** turned or faced inward, toward the central axis; said of stamens whose anthers dehisce on the side facing inward.
- involucel:** a secondary involucre.
- involucral:** of the involucre.
- involucrate:** having an involucre.
- involucre:** one or more whorls or series of small lvs. or bracts that are close underneath a fl. or infl.; the individual bracts termed phyllaries by some. Ex: subtending the heads of most members of the Compositae.
- involute:** a longitudinal curving or rolling upwards as opposed to revolute.
- irregular flower:** a flower that can be cut longitudinally into two equal halves at only one place; one having some parts different from other parts in the same series; a flower that is not symmetrical when in face view; a zygomorphic flower.
- isodiametric:** as broad as tall.
- jointed:** having nodes or points of real or apparent articulation.
- jugum:** a pair, as of leaflets.
- junctions:** winter nodes.
- juvenile:** an early phase of plant growth, usually characterized by non-flowering, vigorous increase in size, and often thorniness.
- keel:** of a papilionaceous corolla, the two front petals united along lower margin into a boat-shaped structure enveloping the pistil and stamens.
- key:** a small indehiscent fruit with a wing.
- knees:** pointed or domelike outgrowths from baldcypress roots, rising above the water.
- labellum:** a modified petal; the enlarged spreading or pouch-like lip of the orchid flower.
- labiate:** lipped, as in the corolla of most mints; as a proper noun, a member of the Labiatae family.
- lacerate:** irregularly torn or cleft.
- lacinate:** slashed into narrow pointed incisions.
- lactiferous:** milky.
- lacuna:** a cavity, hole or gap.

lageniform: gourd-shaped.

lamellae: thin flat plates or laterally flattened ridges.

lamellate: made up of thin plates.

lamina: a blade.

lanate: woolly; with long intertwined curly hairs.

lanceolate: much longer than wide, broadest below the middle and tapering to the apex.

lanuginose: cottony or woolly; downy, the hairs somewhat shorter than in lanate.

lanulose: very short woolly.

lateral: borne at or on the side, as flowers, buds or branches.

lateral bud: a bud borne in the axil of a previous season's leaf.

latex: milky sap.

lax: loose; the opposite of congested.

leader: the primary or terminal shoot, trunk of a tree.

leaf: the whole organ of photosynthesis, characterized by an axillary bud most of the year.

leaf ratio: the fraction obtained by dividing length by width.

leaf scar: the mark remaining after the leaf falls off a twig.

leaflet: a foliar element of a compound leaf.

legume: a dry fruit dehiscing along both sutures and the product of a single carpel (simple ovary). Ex: pea, most beans.

lemma: the outer or lowermost bract of the two immediately inclosing a grass flower.

lenticel: a small corky spot on young bark made of loosely packed cells, providing gaseous exchange between the inner tissues and the atmosphere.

lenticular: lens-shaped, the sides usually convex.

lepidote: covered with minute scurfy scales.

liana: a tropical woody vine.

lignified: woody, hardened.

ligulate: strap-shaped; a leaf blade with the sides essentially parallel and abruptly terminated.

ligule: (1) a strap-shaped organ; (2) (in grasses) a minute projection from the top of the leaf sheath; (3) the strap-shaped corolla in the ray flowers of Composites.

limb: the expanded, and usually terminal, part of a petal (as in *Dianthus*), or of a gamopetalous corolla as distinguished from the often constricted tube.

linear: long and very narrow, as in blades of grass.

lineate: lined; bearing thin parallel lines.

lined: lightly ridged or ribbed.

lingulate: tongue-shaped.

lip: one of the parts of an unequally divided corolla or calyx; these parts are usually two, the upper lip and the lower lip, although one lip is sometimes wanting; the seemingly lower lip of orchid fls. (the labellum) has this position because of a twisting of the pedicel or receptacle.

lobe: a projecting part or segment of an organ as in a lobed ovary or stigma; usually a division of a lf., calyx, or petals cut to about the middle (i.e. midway between margin and midrib).

locule: a cell or compartment of an ovary, anther or fruit.

loculicidal: see *dehiscent*.

lodicule: minute, gland-like structure at base of grass ovary.

loment: a legume constricted between the seeds (as in peanut) or which separates into one-seeded articulations (as in *Desmodium* or *Lespedeza*).

loose: not compact, irregularly formed.

lorate: strap-shaped.

lunate: crescent-shaped, as a quarter moon.

lustrous: having a slight metallic gloss, less reflective than glossy.

lyrate: having a pinnately compound leaf with the terminal lft. much larger than the lateral lfts. and the latter becoming progressively smaller basally.

macrospore: the larger of two spores (as in *Selaginella*) which on germination produces the female gametophyte; synonymous with megaspore.

marcescent: withering, but the remains persisting.

margin: the edge of a leaf.

marginal: pertaining to the margin.

matted: growing densely, forming a low close ground cover or compact tufts.

mature: a later phase of growth characterized by flowering, fruiting, and a reduced rate of size increase.

mealy: having a mottled, granular appearance.

membranaceous: of parchment-like texture.

meristem: nascent tissue, capable of developing into specialized tissues.

- merous**: referring to the number of parts; as fls. 3-merous, in which the parts of each kind (as petals, sepals, stamens, etc.) are 3 each or in multiples of 3.
- metamorphosed**: changed from one state to a different one.
- microsporangium**: the microspore-containing case; an anther sac.
- microspore**: the smaller of two kinds of spores (as in *Selaginella*) which on germination produces the male gametophyte; sometimes applied to a pollen grain.
- midrib**: the primary-rib or mid-vein of a leaf or lft.
- milky sap**: whitish in color, often thicker than water.
- monadelphous**: said of stamens when united by their filaments. Ex: hollyhock.
- moniliform**: constricted laterally and appearing bead-like.
- monocarpic**: fruiting once and then dying. Ex: some palms and most bamboos.
- monocot**: angiospermous plant having only one cotyledon.
- monoecious**: a species with unisexual fls., having both sexes on the same plant. Ex: corn.
- monogynous**: having a gynoecium of one pistil.
- monopodial**: continuing growth from a terminal bud each year.
- mossy**: describes a matted growth habit, with small overlapping foliage.
- mound**: plant having a massive form, full to the ground.
- mucilaginous**: slimy.
- mucro**: a short, sharp, abrupt tip.
- mucronate**: abruptly terminated by a mucro.
- mucronulate**: minutely mucronate.
- multiple buds**: a terminal or lateral bud crowded by many accessory buds.
- multiple fruit**: one formed from several fls. into a single structure having a common axis, as in pineapple or mulberry.
- mummy**: a dried shrivelled fruit.
- muricate**: rough, due to presence of many minute spiculate excrescences on the epidermis.
- muriform**: with markings, pits, or reticulations arranged like bricks of a wall; as on some seed coats and achenes.
- mutation**: a sudden change in genetic material resulting in an altered individual. Generally disadvantageous to survival.
- naked bud**: one without scales.
- naked flower**: one having no floral envelopes (perianth).
- nascent**: in the act of being formed.
- native**: inherent and original to an area.
- naturalized**: thoroughly established, but originally from a foreign area.
- navicular**: coat-shaped, as glumes of most grasses.
- nectary**: a nectar-secreting gland; may be a protuberance, a scale, or a pit.
- needle**: the slender leaf of many conifers.
- nerve**: a slender rib or vein, especially unbranched.
- netted venation**: the veins reticulated and resembling a fish net; the interstices close.
- neutral flower**: a sterile fl. consisting of perianth without any essential organs.
- nocturnal**: opening at night and closing during the day.
- nodding**: drooping, bending over.
- node**: a joint on a stem, represented by point of origin of a leaf or bud; sometimes represented by a swollen or constricted ring, or by a distinct leaf scar.
- nodulose**: having small, swollen knobs; knot-like.
- notched**: with v-shaped indentations.
- nut**: a dry, indehiscent, 1-celled, 1-seeded fruit having a hard and bony mesocarp; the outermost endocarp may be fibrous or slightly fleshy.
- nutlet**: diminutive nut; applied to one of the four nucules of the fruit of the mint family.
- ob-**: prefix indicating the inverse.
- obcordate**: the apex being cordate.
- oblanceolate**: inversely lanceolate.
- oblate**: flattened at the poles.
- oblique**: lop-sided, as one side of a leaf base larger, wider or more rounded than the other.
- oblong**: longer than broad; rectangular; the sides nearly parallel.
- oblong-lanceolate**: a shape in between the two forms.
- oblong-obovate**: a shape in between the two forms.
- obovate**: inversely ovate, broadest above the middle.
- obovoid**: three dimensional shape of obovate, pear shaped.
- obsolete**: rudimentary.

obtuse: rounded, approaching the semi-circular.

ochrea: a nodal sheath formed by fusion of the two stipules. Ex: *Rumex*, *Polygonum*.

odd-pinnate: see *compound*.

odoriferous: aromatic but questionably pleasant.

oligo-: a prefix meaning few, as oligospermous-few-ovuled.

operculate: provided with a cap or lid (the operculum).

opposite: two at a node, as leaves.

orbiculate: circular or disk-shaped. Ex: leaf of common nasturtium.

orthotropous: said of an ovule or seed when straight and erect, the hilum at the base and micropyle at the apex.

osier: a long lithe stem.

oval: twice as long as broad, widest at the middle, both ends rounded.

ovary: the ovule-bearing part of a pistil; one borne above the point of attachment of perianth and stamens is a *superior ovary*; when below attachment of these floral envelopes it is an *inferior* or *hypogenous ovary*; when intermediate or surrounded by an hypanthium it is a *half-inferior* or *perigynous ovary*.

ovate: egg-shaped in outline, broadest below the middle, like an oval.

ovate-oblong: a combination of the two forms.

ovoid: said of a solid that is three-dimensionally egg-shaped.

ovulate: bearing ovules.

ovule: the egg-containing unit of an ovary, which after fertilization becomes the seed.

paired: occurring in twos.

palamatified: cut palmately about half-way down.

palate: the projecting part of the lower lip of a bilabiate corolla that closes the throat of the corolla or nearly does so. Ex: toad-flax, snapdragon.

palea (Palet): the inner of the two bracts immediately subtending a grass flower; the lower one is the lemma.

palmate: digitate, radiating, fan-like from a common point, as leaflets of a palmately compound lf. or veins of palmately-veined lf.

pandurate: fiddle-shaped.

panicle: an indeterminate infl. whose primary axis bears branches of pedicel led fls. (at least basally so); a branching raceme.

paniculate: bearing panicles.

papilionaceous: having a pea-like corolla that is comprised of standard, wings and keel.

papillate: bearing minute, pimple-like protuberances (Papillae).

pappillose: with small nipple-like projections.

pappus: the modified calyx of Composites, borne on the ovary (usually persisting on the achene) and represented by hairs, bristles, awns, scales, or others.

parallel: especially of veins, running side by side from base to tip.

parallel venation: the veins extending in more or less parallel fashion from base to apex.

parenchyma: unspecialized living cells, present in the pith.

parietal: borne on the side walls of an ovary (or capsule), or on invaginations of the wall that form incomplete partitions or septae within the ovary.

parted: cleft or cut not quite to the base.

pectinate: comb-like or pinnatifid with very close narrow divisions or parts; also used to describe spine conditions in cacti when small lateral spines radiate as comb-teeth from areole.

pedate: a palmately divided or compound lf. whose two lateral lobes are again cleft or divided.

pedicel: the stalk of a flower or fruit when in a cluster or when solitary.

peduncle: the stalk of a fl. cluster or a single fl. when that fl. is solitary, or the remaining member of a reduced infl. (as in *Euphorbia* where a constriction designates the "break" between peduncle and pedicel).

pellucid: clear or translucent, said of minute glandular dots that can nearly be seen through when viewed in transmitted light.

peltate: having the petiole attached inside the margin, such a lf. is typically shield-shaped.

pendulous: more or less hanging or declined.

penniveined: pinnately arranged.

percurrent: the main trunk continuing through to the top.

perennial: of three or more seasons duration.

perfect flower: having both functional stamens and pistils.

perfoliate: the leaf-blade surrounding the stem. Ex: *Uvularia perfoliatus*.

perianth: the two floral envelopes of a fl.; a collective term embracing both corolla and calyx as a unit; often used when it is not possible to distinguish one series from the other (as in most monocots) and the parts then called tepals.

pericarp: a term used by some to designate a fruit; technically, the ovary wall.

periderm: a protective layer of corky cells.

- perigynous:** borne around the ovary but not fused to it, as when calyx, corolla and stamens are borne on the edge of a cup-shaped hypanthium. Ex: coral-bells, fuchsia, evening-primrose.
- persistent:** adhering to position instead of falling, whether dead or live.
- personate:** concealed; a corolla whose tube is closed by a palate, as in snapdragon.
- perulate:** scale-bearing, as a scaly bud.
- petal:** one unit of the inner floral envelope or corolla of a polypetalous fl., usually colored and more or less showy.
- petaloid:** a structure not a petal (for example a sepal) that is of the color and shape of a petal; resembling a petal.
- petiole:** leaf-stalk.
- petiolule:** leaflet-stalk.
- phylloclad:** a branch, more or less flattened, functioning as a leaf. Ex: Christmas cactus.
- phyllodium:** a flattened, expanded petiole without blade and functioning as a lf. Ex: some spp. *Acacia*.
- phyllotaxy:** arrangement of lvs. or of floral parts on their axis.
- picturesque:** striking in an unusual way.
- pilose:** shaggy with soft hairs.
- pinked:** notched.
- pinna:** the lft. of a compound lf.; of ferns, the primary division attached to the main rachis; feather-like.
- pinnate:** compounded with the lfts. or segments along each side of a common axis or rachis; feather-like.
- pinnatifid:** pinnately cleft or parted.
- pinnatisect:** pinnately cut to midrib or almost to it.
- pinnule:** the lft. of a pinna; a secondary lft. of a pinnately decompound lf.
- pistil:** the unit of the gynoecium comprised of ovary, style and stigma: it may consist of 1 or more carpels; the former with a single placenta is a *simple pistil*, the latter with 2 or more carpels is a *compound pistil*. See *carpel* or *ovary*.
- pistillate:** having no functional stamens (staminodia may be present) in the flower.
- pith:** the central part of a twig, usually lighter or darker than the wood.
- pitted:** marked with small depressions.
- placenta:** that place in the ovary where ovules are attached. A location, not a structure.
- placentation:** the arrangement of ovules within the ovary. Several types are recognized, among them are: *parietal placentation* (see *parietal*), *axile placentation*, the ovules borne in the center of the ovary on the axis formed by the union and fusion of the septae (partitions) and usually in vertical rows; in 2-celled ovaries they are borne in the center and on the cross partition or on a proliferation of it often filling the loculi; *free central placentation*, the ovules borne on a central column with no septae present; *basal placentation*, the ovules few or reduced to one and borne at the base of the ovary, the solitary ovule often filling the cavity; *lamellate placentation*, the ovules completely sunken in spongy ovarian and receptacular tissues with only the discoid stigmas exserted.
- plicate:** folded, as in a folding fan, or approaching this condition.
- plugged pith:** having cross partitions at the nodes.
- plumose:** feather-like, plummy.
- pod:** a dry dehiscent fruit; a general term.
- pollen:** microspores contained within an anther; sometimes agglutinated into a mass.
- pollinium:** an agglutinated, coherent mass of pollen. Ex: milkweeds, orchids.
- polycarpic:** flowering and fruiting many times. See *monocarpic*.
- polygamo-dioecious:** having male and female fls. on separate plants, but these plants having perfect flowers as well.
- polygamous:** bearing unisexual and bisexual flowers on the same plant.
- polymorphism:** multiple shapes for same organ as in the leaves of *Morus* species.
- polypetalous:** with a corolla of separate petals. See *corolla*.
- polysepalous:** having a calyx of separated sepals.
- pome:** a type of fleshy fruit represented by the apple, pear and related genera, resulting from a compound ovary.
- poricidal:** see *dehiscence*.
- porrect:** said of cactus spines when the laterals are at right angles to the central one of an areole.
- posterior:** at or toward the back; opposite the front; nearest the axis; away from the subtending bract.
- preformed:** already having definite structure, such as leaves within a bud.
- prehensile:** clasping or coiling in response to touch.
- prickle:** an excrescence of bark that is small, weak, and spine-like.
- primocane:** the first year's shoot or cane of a biennial woody stem. Ex: *Rubus*.
- procumbent:** lying flat on the ground but the stem not rooting at nodes or tip.
- prominent:** projecting outward, conspicuous.
- prostrate:** lying flat on the ground; a general term.
- protandrous:** with anthers maturing before the stigma.

protogynous: having stigma receptive to pollen before pollen is released from anthers of same fl.

proximal: toward the base, away from the apex.

pruinose: having a coarse, granular, dust-like, waxy bloom.

pseudo-terminal bud: seemingly the terminal bud of a twig, but actually the upper-most lateral bud with its subtending lf. scar on one side and the scar of the terminal bud often visible on opposite side.

puberulent: minutely pubescent as viewed with a lens.

pubescent: covered with short soft hairs; a general term.

pulvinate: cushion-shaped.

pulvinus: a minute gland or a swollen base of the petiole or petiolule responding to vibrations. Ex: sensitive-plant (*Mimosa*).

punctate: with translucent or covered dots, depressions, or pits.

pungent: terminated by a sharp stiff point; sharp and acid to taste or smell.

pustular: blistery, usually minutely so.

pyramidal: broadest at base, tapering apically; pyramid-shaped.

pyrene: the pit or "seed" of a drupelet.

pyriform: pear-shaped.

pyxidium: pyxis: a capsule dehiscing circumscissilely.

quadrangular: four angled, of pith or a twig.

raceme: a simple indeterminate inflorescence with pedicel led flowers.

racemose: having flowers in racemes.

rachilla: a diminutive or secondary axis; a branch of a rachis; the minute axis bearing the individual florets in grass and sedge spikelets; the secondary axes of decomposed fern fronds.

rachis: axis bearing leaflets or the primary axis of an infl.; the axis bearing pinnae of a fern frond.

radial: arranged around and spreading from a common center.

radiate: (1) said of a Composite infl. when bearing ray fls.; (2) star-shaped or spreading from a common center.

radical: of or pertaining to the root.

radicle: the embryonic root of a seed.

ramified: branched.

ramiform: branching.

ranked: foliage is arranged in longitudinal planes around the stem.

raphides: needle-like crystals in plant tissues.

ray: (1) the ligulate or lorate corolla of some composite flower; (2) the fl. of a Composite having a ligulate or strap-shaped corolla; (3) the axes of an umbel or umbel-like inflorescence.

receptacle: a torus; the distal end of a flower-bearing axis, usually more or less enlarged, flattened, or cup-like on which some or all of the flower parts are borne. Ex: Compositae, Onagraceae.

reclining: having an axis that is falling back or bent down from the vertical.

recurved: bent or curved backward, usually roundly or obtusely so. *See reflexed.*

reduced: smaller or simpler than normal.

reduplicate: said of buds whose components have their edges rolled outward in aestivation.

reflexed: bent abruptly backward or downward.

regular flowers: (1) a flower that can be cut longitudinally into two equal halves along an indefinite number of radii; (2) one having the parts of any one series all alike and uniformly disposed about the axis, as petals all alike, sepals all alike, etc.; a symmetrical or actinomorphic fl.

remote: widely spaced.

reniform: kidney-shaped.

repandate: having a weakly sinuate margin, one slightly uneven.

repent: creeping along the ground and rooting at the nodes.

replum: the partition separating the two loculi or cells or cruciferous fruits.

resin duct: a lengthwise or transverse canal carrying resins.

resinous: secreting a viscid exudate.

reticulate: like a net, the interstices closed.

retorse: turned back or downwards, usually applied to armament or vesture.

retuse: notched slightly at a usually obtuse apex.

revolute: rolled toward the back, as a margin tightly or laxly rolled along the lower side.

rhizome: an underground stem distinguishable from a root by presence of nodes, buds or scale-like lvs.

rhombic: with four nearly equal sides, but unequal angles, diamond shaped.

rhombic-ovate: somewhere between egg and diamond shaped.

rhomboidal: of the shape of a rhomboid.

rib: conspicuous vein of a lf.; a prominent ridge.

root: the descending axis of the plant, without nodes and internodes, usually underground.

rootlet: a subdivision of a root, also an aerial root.

- rosette:** a crown of lvs. radiating from a st. and at or close to the surface of the ground.
- rostellum:** a small beak: a projection from the distal edge of the stigma in many monandrial orchids.
- rostrate:** beaked.
- rosulate:** in rosettes, or rosette-like in form.
- rotate:** wheel-shaped, a corolla whose limb flares out at right angles to the fl. axis and with no conspicuous tube produced; a flat circular or disc-like limb.
- rotund:** orbicular and inclining to be oblong.
- rudiment:** the beginning of an undeveloped member.
- rufous:** reddish brown.
- rugose:** wrinkled, usually covered with wrinkles.
- ruminate:** mottled in appearance, in a surface or tissue due to dark and light zones or irregular outline.
- runcinate:** pinnatifidly incised, the incision sharp and pointing backward. Ex: some *Taraxacum* leaves.
- runner:** a slender trailing shoot that usually roots at the tip and some nodes.
- saccate:** bag-shaped, pouchy.
- sagittate:** shaped like an arrow-head with the basal lobes pointing directly downward (backward) or inward.
- salverform:** said of a corolla with a slender tube and an abruptly expanded flat limb extending at right angles to the tube. Ex: *Phlox*, *Galium*, most primulas.
- samara:** a dry indehiscent fruit bearing a wing (the wing may be limb-like or envelop the seed and be wafer-like). Ex: maple, ash, *Ptelea*.
- sarmentose:** producing long flexuous runners.
- scabrous:** rough or gritty to the touch; rough-pubescent.
- scalariform:** said of pits or pith partitions when arranged like ladder rungs.
- scale:** a small and usually dry bract or vestigial leaf or a structure resembling such.
- scandent:** climbing, usually without tendrils.
- scape:** a leafless peduncle arising from the basal rosette of a few or no basal leaves; sometimes a few scale-like lvs. or bracts may be borne on it; a scape may be one or many-flowered.
- scapose:** bearing its fls. on a scape.
- scar:** the mark left from a former attachment.
- scarious:** thin, dry, membranous and usually translucent margins or parts that are not green in color.
- scattered:** not in any patterned arrangement, especially of vascular bundle scars.
- schizocarp:** a dry dehiscent fr. that splits into two halves. Ex: maple.
- scorpioid-cyme:** a determinate infl. (often seemingly indeterminate) that is coiled with the fls. 2-ranked and borne alternately at the right and the left. Ex: forget-me-not, heliotrope.
- scrambler:** plant that climbs without twining or grasping in some way.
- scurfy:** describes a surface covered with bran-like particles.
- scutate:** like a small shield.
- secund:** one-sided, in that the fls. are seemingly borne in a one-sided infl.
- seed:** a fertilized ripened ovule that contains an embryo.
- segment:** a portion of a leaf or perianth that is divided but not compound.
- semi-cordate:** partly heartshaped.
- semi-evergreen:** green for only a part of the winter, or only part of the foliage fully evergreen.
- sepal:** one of the units comprising the calyx; a usually green foliaceous element subtending the corolla.
- septate:** divided by partitions.
- septicidal:** *see dehiscence*.
- septum:** a partition.
- sericeous:** *see silky*.
- serotinous:** produced late in the season, late to open; having cones that remain closed long after the seeds are ripe.
- serrate:** saw-toothed, the teeth pointing forward.
- serrulate:** minutely serrate.
- sessile:** without a stalk.
- seta:** a bristle.
- setaceous:** bristle-like.
- setose:** covered with bristles.
- shaggy:** covered with or resembling long rough woolly hair.
- sheath:** any elongated, more or less tubular structure enveloping an organ or part.
- shrub:** a woody plant that is never tree-like in habit and produces branches or shoots from or near the base.
- silicle:** the short fr. of some crucifers, which is usually not more than 1 1/2 times as long as wide.
- siliqua:** the elongated fr. of some crucifers, usually 3 times as long as wide or longer.
- silky:** covered with soft appressed fine straight hairs; sericeous.
- simple:** said of a lf. when not compound, of an infl. when unbranched.
- sinuate:** with a strongly wavy margin.

sinus: the space between two lobes, segments, or divisions; as of lvs. or perianth parts.

smooth: not roughened, not warty.

solitary: occurring alone, not paired or clustered.

sori: *see sorus*.

sorus: cluster of sporangia (of ferns), appearing usually as a dot on the dorsal surface of a frond.

spadix: a fleshy usually club-shaped axis on which are borne fls. and which is generally enveloped by a spathe; the infl. of most Araceae; sometimes employed for the branched infl. of palms.

spathe: the bract or modified leaf surrounding or subtending a flowering infl. (usually a spadix); it may be herbaceous, colored, and "flower-like" as in the calla-lily or the anthurium, or hard, dry and woody in many palms. By some the term is restricted to members of the Araceae.

spathe valves: one or more herbaceous or scarious bracts that subtend an inflorescence or a flower.

spatulate: spoon-shaped.

species: a natural group of plants composed of similar individuals which can produce similar offspring; usually including several minor variations.

spicate: with spikes.

spicula: a cymule or small cyme.

spike: (1) a usually unbranched, elongated, simple, indeterminate infl. whose fls. are sessile; the fls. may be congested or remote; (2) a seemingly simple infl. whose "fls." may actually be composite heads (*Liatris*).

spikelet: (1) a secondary spike; (2) one part of a compound infl. which of itself is spicate; (3) the floral unit, or ultimate cluster, of a grass infl. comprised of fls. and their subtending bracts.

spine: an excrescence of st., strong and sharp-pointed. Ex: spines of hawthorns.

spinescent: more or less spiny.

spinose: beset with spines.

spirally arranged: the actual pattern of alternate leaves.

spongy: porous, as parenchyma cells of the pith.

sporangium: a spore-containing case, as in ferns.

spore: a minute reproductive body comprised of a single gametophytic cell.

sporocarp: a body containing sporangia or spores.

sporophyll: a spore-bearing leaf.

spray: a branchlet with foliage.

spreading: growing outward or horizontally.

spur: a tubular or sac-like projection from a fl. and usually from a sepal or petal.

squamate: with small scab-like projection from a fl. and usually from a sepal or petal.

squamose: covered with small scales, more coarsely so than when lepidote.

squarrose: with branches spreading and recurved at the ends.

stalk: a supporting structure of a leaf, flower or fruit.

stalked bud: a bud whose outer scales are attached above the base of the bud axis.

stamen: the unit of the androecium and typically comprised of anther and filament, sometimes reduced to only an anther; the pollen-bearing organ of a seed plant.

staminate: describes an imperfect flower with only functional stamens, male.

staminate flower: *see flower*.

staminode (staminodium): a sterile stamen reduced to a non-functional filament-like stalk, a gland, or sometimes expanded and petal-like; borne in the same or adjacent whorl as the functional stamens.

standard: (1) of a papilionaceous fl., the upper usually expanded, more or less erect petal; (2) the erect petals of an iris fl. as opposed to the broader and often drooping falls.

stellate: star-like; stellate hairs having radiating branches or are separate hairs aggregated in star-like clusters; hairs once or twice forked often are treated as stellate.

stellate-pubescent: with hairs in small starlike tufts.

stem: the primary axis of a plant having foliage and flowers opposed to the root axis.

sterigma: the raised base from which some small evergreen leaves finally fall (spruces).

sterile: barren, not able to produce seed.

stigma: the usually distal end of the pistil that receives the pollen, of varied shapes and surfaces.

stipe: (1) a naked stalk; (2) the petiole of a fern frond.

stipel: a stipule of a lft.

stipellate: having stipels at the base of the leaflets.

stipular, stipulate: having stipules at the base of the leaves.

stipule: a basal appendage of a petiole, usually one at each side, often ear-like and sometimes caducous.

stipule scar: a pair of marks left after the stipules fall off, to either side of the leaf scar.

stolon: a horizontal stem that roots at its tip and there gives rise to a new plant.

stoloniferous: bearing slender stems just on or under the ground which root at the tips.

stoma: a minute pore in the epidermis, especially in the lower surface on the leaf.

stomatiferous: bearing stomata.

stone: the hard usually one-seeded endocarp of a drupe.

stratified: arranged in horizontal layers.

striate: with fine longitudinal lines, channels or ridges.

strict: rigidly erect.

strigose: with sharp, stiff, straight and appressed hairs.

strobilus: a cone.

style: the more or less elongated part of a pistil between the stigma and the ovary.

stylopodium: a disk-like enlargement at the base of a style.

subcontinuous pith: with occasional but not regular gaps.

submerged bud: a bud hidden by the petiole or embedded in the callus of the leaf scar.

subopposite: pairs of leaves close but not exactly at the same level on the stem.

subpetiolar: under the base of the petiole.

subtend: to stand immediately beneath.

subulate: awl-shaped.

succulent: thickened, juicy, fleshy tissues that are more or less soft in texture.

sucker: a shoot arising from the roots or from beneath the surface of the ground; also the adhering discs of a vine.

suffrutescent: a plant whose stems are woody basally but herbaceous above, dying back to the woody portion at the close of each growing season. Ex: *Alyssum saxatile* (now *Aurinia saxatile*), rock rose, *Caryopteris*.

sulcate: deeply grooved lengthwise.

superficial: on the surface, not connected to inner tissues.

superior ovary: see *ovary*.

superposed bud: accessory bud above the true lateral bud.

supine: lying flat, face upwards.

suture: a line of dehiscence or groove marking a face of union.

syconium: the fruit of a fig.

symmetrical: actinomorphic or regular (flower) to the extent that the parts of the several series (calyx, corolla, stamens) are each of the same number.

symmetrical flower: one having the same number of parts in each envelope (calyx and corolla).

sympetalous: the petals united at least at the base; synonym for gamopetalous.

sympodial: continuing growth by the development of an axillary bud and not the terminal bud, season after season.

sympodial inflorescence: a determinate infl. that simulates an indeterminate infl., as if a scorpioid cyme were straight rather than circinate.

syncarp: a fleshy aggregate fruit.

syncarpous: having a gynoecium with all the carpels united.

syngenesious: stamens connate by their anthers in a cylinder about the style. Ex: Compositae family.

tailed: said of anthers having caudal appendages.

tapering: gradually decreasing towards an end.

taxonomy: the area of botany dealing with the classifying and naming of plants.

tendrill: a modified stem or leaf, usually filiform, branched or simple, that twines about an object providing support.

tepal: a segment of perianth not differentiated into calyx or corolla. Ex: tulip, magnolia.

terete: cylindrical, or at least circular in cross section.

terminal: at the tip or distal end.

ternate: in threes.

testa: the outer coat of a seed.

tetradynamous: with an androecium of 6 stamens, four longer than the other two, as in Cruciferae.

texture: the effect of the surface structure.

thallus: a foliaceous organ, not differentiated into the stem and foliage and not bearing true roots.

thicket: a dense growth of shrubs, a copse.

thorn: a modified twig which has tiny leaf scars and buds; can be single or branched.

throat: the opening into the lower end of a gamopetalous corolla, the point where the limb joins the tube.

thyrs: compact panicle-like infl. whose distal end is indeterminate and the lateral branches determinate.
Ex: lilac (*Syringa vulgaris*).

tomentose: densely woolly, the hairs soft and matted.

tomentulose: diminutive of tomentose; delicately tomentose.

tomentum: the dense matted hairs.

toothed: the margin broken up into small rather regular segments.

torose: cylindrical with constrictions at intervals, slightly moniliform.

torsion: twisting.

torulose: twisted or knobby; irregularly swollen at close intervals.

torus: see *receptacle*.

trailing: prostrate and not rooting.

translucent: transmitting light but diffuse enough to distort images.

transverse ridge: one which runs across the stem from one leaf scar to its pair on opposite twigs.

tree: a woody plant with one main stem at least 12 to 15 feet tall, and having a distinct head in most cases.

triangular-ovate: a flattened angular egg shape.

trichoma: a bristle.

trifid: three-cleft.

trifoliate: three-leaved. Ex: *Trillium*.

trifoliolate: with a leaf of three lfts.

tripinnate: with compounded pinnules.

triquetrous: three-angled.

triternate: a biternate lf. again divided in 3's. Ex: many spp. of *Thalictrum*.

truncate: as if cut off at right angles to the primary axis; a term applicable to bases or apices.

tuber: a short, thickened organ, usually-but not necessarily-an underground stem.

tubercle: a miniature tuber, tuber-like body or projection.

tubular: having petals, sepals, or both united into a tube.

tuft: a clump of hairs growing close together.

tumid: swollen.

tunic: a coat about an organ, often fibrous or papery. Ex: about the crocus corm or tulip bulb.

tunicated: with concentric layers, often of fleshy scales. Ex: onion bulb.

turbinate: inversely conical, top-shaped.

turgid: swollen to firmness.

turion: a young shoot or sucker. Ex: asparagus stalk.

twig: the shoot of a woody plant representing the growth of the current season.

twig scar: mark left by the sloughing of a length of dead twig tissue.

twiggy: having many divergent twigs.

twining: the stem winding about a support.

umbel: an indeterminate infl., usually but not necessarily flat-topped with the pedicels and peduncles (termed rays) arising from a common point, resembling the stays of an umbrella.

umbellate: having umbels.

umbellet: a secondary umbel.

umbo: a conical projection arising from the surface.

unarmed: without a sharp defense such as spines or bristles.

uncinate: hooked at the tip.

undulate: wavy, as a leaf margin.

unguiculate: narrowed into a petiole-like base; clawed.

unijugate: a compound lf. reduced to a single pair of leaflets.

unilateral: one-sided.

unilocular: one-celled or with a single cavity.

unisexual flowers: of one sex only. See *flower*.

urceolate: urn-shaped; constricted at the throat.

utricle: a small dry thin-walled, usually dehiscent, 1-seeded fruit; an achene whose pericarp is loose and readily removed. Ex: *Amaranthus*.

vaginate: sheathed.

valvate: (1) dehiscent by valves; (2) meeting by the edges without overlapping, as lvs. or petals in the bud.

valve: a separable part of a dehiscent fruit or stamen; the unit into which a capsule splits or divides in dehiscent.

variegated: striped, margined or mottled with a color other than green, where green is normal.

variety: subdivision of a species having a distinct though often inconspicuous difference, and breeding true to that difference. More generally also refers to clones.

vascular bundle: a discrete group of conducting vessels.

vascular bundle scar: a minute spot within the leaf scar where the vessels were positioned.

vasiform: an elongated funnel-shaped object.

vein: a vascular rib of the leaf.

velutinous: clothed with a velvety indumentum comprised of erect straight dense moderately firm hairs.

venation: arrangement of veins.

ventral: relating to the anterior or inner face or part of an organ, the opposite of dorsal.

ventricose: a one-sided swelling or inflation, more pronounced than gibbous.

venulose: with very fine veins.

vernal: related to spring.

vernation: the arrangement of leaves within a bud.

verrucose: having a wart-like surface.

versatile: moving freely because of attachment near the middle, as an anther attached crosswise medianly to the filament.

vertical: having broad faces perpendicular to the earth.

verticil: a whorl.

verticillate: arranged in whorls.

verticillate inflorescence: one with the flowers in whorls about the axis, the whorls remote from one another (as in many salvias) or congested into head-like structures (catnip). Such whorls are false-whorls since they are actually sessile cymes arranged opposite one another in the axils of opposite bracts or leaves.

vesicle: a small bladdery sac or cavity filled with air or fluid.

vestige: the remains of an exhausted or dead member.

vesture: any substance on or arising from the surface rendering it other than glabrous.

vexillum: the petal of a papilionaceous corolla known also as the standard; the upper broad petal.

villous: having long, soft, shaggy hairs that are not matted.

vine: a slender-stemmed climbing or trailing plant.

virgate: wand-like; long straight and slender.

viscid: sticky or with appreciable viscosity.

vittatae: the oil tubes of Umbelliferae (Apiaceae), especially of their fruits.

voluble: twining.

warty: marked with rounded tubercles, rougher than granules.

watery sap: thin and clear.

wavy: alternating concave and convex curves.

weeping: dropping conspicuously, pendent.

whorl: arrangement of three or more structures arising from a single node.

whorled: in a whorl, as leaves.

wilt: to become limp and lose turgor through a deficit of water.

wing: (1) the lateral petal of a papilionaceous flower; (2) a dry, thin, membranous appendage.

wither: to dry up and shrivel.

wood: a dead, hard xylem tissue.

woolly: having long, soft, more or less matted hairs; like wool.

×: indicates a hybrid; symbol is a multiplication sign, not the letter "x".

zig-zag: bent back and forth at the nodes.

zone: an area restricted by a range of annual average minimum temperatures, used in describing hardiness.

zygomorphic: irregular, not symmetrical.

Vinca major var. *oxyloba* 1232
Vinca minor 412, 1230, 1231
Vitex agnus-castus 1232, 1233
Vitex agnus-castus f. *alba* 1234
Vitex agnus-castus f. *latifolia* 1234
Vitex agnus-castus var. *latifolia* 1233, 1234
Vitex negundo 1232, 1233
Vitex negundo var. *heterophylla* 1233
Vitex negundo var. *incisa* 1233
Vitex rotundifolia 1233
Vitex trifolia 1233
Vitis 111, 1234
Vitis aestivalis 1234
Vitis cinerea 1234
Vitis coignetiae 1235
Vitis labrusca 1234
Vitis riparia 1234
Vitis rotundifolia 1234, 1235
Vitis vinifera 1235
- ## W
- Washingtonia filifera* 788
Washingtonia robusta 788
Weigela 273
Weigela coraeensis 1240
Weigela decora 1240
Weigela decora var. *amaglensis* 1240
Weigela florida 1236
Weigela florida var. *venusta* 1239
Weigela japonica 1239, 1240
Weigela japonica var. *sinica* 1240
Weigela maximowiczii 1240
Weigela middendorffiana 1240
Weigela praecox 1239
Weigela sinica 1240
Weigela subsessilis 1240
Wisteria brachybotrys 1242
Wisteria floribunda 1240, 1242
Wisteria xformosa 1242
Wisteria frutescens 1241, 1243
Wisteria frutescens var. *macrostachya* 1243
Wisteria macrostachya 1243
Wisteria sinensis 112, 1242, 1243, 1244
Wollemia nobilis 1244
- ## X
- Xanthoceras sorbifolium* 1245
Xanthocyparis nootkatensis 250
Xanthorhiza simplicissima 1245
- ## Y
- Yucca* 1246
Yucca filamentosa 1246, 1247
Yucca flaccida 1247
Yucca glauca 1247
Yucca glauca var. *stricta* 1247
Yucca gloriosa 1247
Yucca recurvifolia 1247
Yucca smalliana 1247
- ## Z
- Zanthoxylum americanum* 1248
Zanthoxylum clava-herculis 1248
Zanthoxylum piperitum 1248
Zanthoxylum schinifolium 1249
Zanthoxylum simulans 1249
Zelkova abelicea 1251
Zelkova carpinifolia 1251
Zelkova schneiderana 1251
Zelkova serrata 1172, 1249, 1251
Zelkova sinica 1251, 1252
Zelkova xverschaffeltii 1251
Zenobia pulverulenta 1252
Zenobia pulverulenta f. *nitida* 1252
Ziziphus jujuba 1252
Ziziphus jujuba var. *inermis* 1253
